Preface

Thank you for using our products. This manual matches the RGOS Release 11.9(2)B2.

Audience

This manual is intended for:

- Network engineers
- Technical support and servicing engineers
- Network administrators

Obtaining Technical Assistance

Related Documents

Documents	Description
Command Reference	Describes the related configuration commands, including command modes, parameter descriptions, usage guides, and related examples.
Hardware Installation and Reference Guide	Describes the functional and physical features and provides the device installation steps, hardware troubleshooting, module technical specifications, and specifications and usage guidelines for cables and connectors.

Conventions

This manual uses the following conventions:

Convention	Description
boldface font	Commands, command options, and keywords are in **boldface**.
italic font	Arguments for which you supply values are in *italics*.
[ ]	Elements in square brackets are optional.

{ x | y | z }	Alternative keywords are grouped in braces and separated by vertical bars.
[x | y | z]	Optional alternative keywords are grouped in brackets and separated by vertical bars.

Symbols

Means reader take note. Notes contain helpful suggestions or references.

Means reader be careful. In this situation, you might do something that could result in equipment damage or loss of data.

WLAN Basic Configuration

1. Configuring APMG
2. Configuring STA Management
3. Configuring CAPWAP
4. Configuring WBS
5. Configuring WLAN WBS FWD
6. Configuring ETH-MNG
7. Configuring DATA-PLANE
8. Configuring WLOG
9. Configuring Roaming

1 Configuring APMG

1.1 Overview

Tailored for the wireless network structures that support centralized management, AP Management (APMG) implements centralized management and configuration of access points (APs).

A Wireless Local Area Network (WLAN) refers to a network system that allows different PCs to communicate and share resources with each other by interconnecting different PCs through wireless communication technologies. The essence of a WLAN is that PCs are interconnected with each other in wireless rather than wired mode, thus constructing a network and allowing terminals to move more flexibly.

A traditional WLAN adopts the fat AP network structure in which APs work independently. On the traditional WLAN, each AP must be separately configured and managed, which increases the complexity of network management and O&M workload. In addition, problems, such as radio interference between APs and roaming of wireless users, cannot be effectively resolved due to poor collaboration between APs. To address these issues, a wireless network structure that supports centralized management emerges. This network structure consists of access controllers (ACs) and fit APs, and is also called fit AP network structure. In this network structure, APs are connected to ACs through the Control and Provisioning of Wireless Access Points (CAPWAP), and ACs perform centralized management on APs.

Protocols and Standards

- RFC5415: Control And Provisioning of Wireless Access Points (CAPWAP) Protocol Specification
- RFC5416: Control and Provisioning of Wireless Access Points (CAPWAP) Protocol Binding for IEEE 802.11

1.2 Application

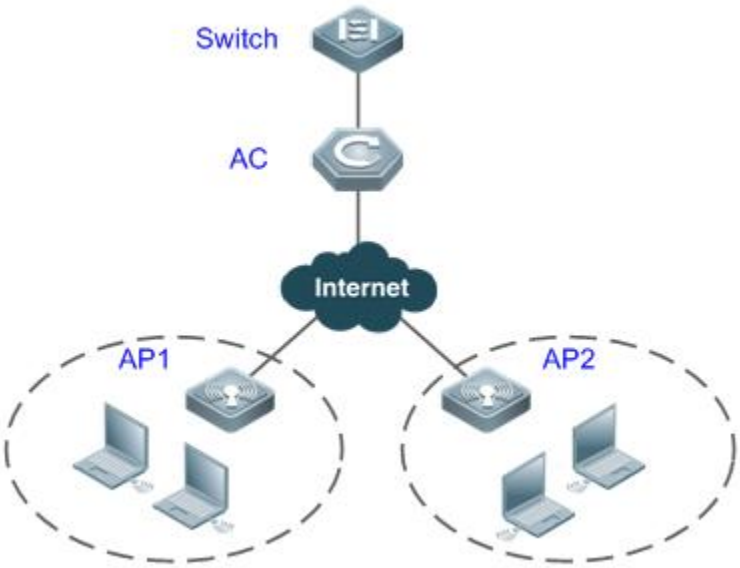
Application	Description
Fit AP Network Structure	This type of network consists of wired switches, ACs, and fit APs.

1.2.1 Fit AP Network Structure

Scenario

A fit AP network consists of wired switches, ACs, and fit APs. In the fit AP network structure, APs serve as the simple wireless access points and do not have the management or control function. The AC manages all the APs in a centralized manner, and pushes control policies to APs, and it is not necessary to configure APs one by one. As shown in Figure 1-1, the AC is connected to multiple APs through the CAPWAP tunnels. Users only need to perform configuration management on all the connected APs through the AC.

Figure 1-1 Simple fit AP network topology



Remarks	AP1 and AP2 are AP devices in fit AP mode.

Deployment

- Configure a meaningful name for each AP so that the AP can be configured based on the name.
- Create a WLAN and configure WLAN-related properties.
- Create an AP group and add APs to a specified AP group so that all the APs in this AP group can be configured in a centralized manner through the AP group.
- Deploy the WLAN on all the APs in the AP group through configuration of the AP group, after which the APs can provide the WLAN access service for external entities and wireless terminals users can access the WLAN.

1.3 Features

Basic Concepts

AP

AP is an access point used by wireless terminals to access a wired network. It is equivalent to a bridge for communication between wireless terminals and a wired network.

AC

AC is a wireless access controller. It is connected with APs through the wired network to manage and control APs in a centralized manner.

AC Cluster

AC cluster is also called AC redundancy. With this function, multiple ACs with different priorities are designated for an AP. When the connection between the AP and a high-priority AC is down, the AP is connected to a low-priority AC (standby AC). When the connection with the high-priority AC is recovered, the AP disconnects the CAPWAP tunnel with the low-priority AC, and sets up a CAPWAP tunnel with the high-priority AC again.

Overview

Feature	Description
Configuration of AC Authorization Key	Configure the license activation/deactivation key of an old version system.
Configuration of AC Parameters	Configure parameters, such as the AC name and Trap message control.
Configuration of AP Parameters	Configure parameters, such as the AP name, Telnet user name and password, and periodical statistics report interval.
Configuration of AP Behaviors	Configure AP behaviors, including daily scheduled restart of an AP, restoration of AP factory settings, and AP reset.
AP Group Management	Manage APs through the AP group to reduce the workload incurred by configuring APs one by one.
AP Quantity Limit	Limit the maximum number of APs that can be connected to the AC.
AP Compliance Check	Implement the AP access control based on the bound MAC address.
AP Access Authentication	Authenticate the AP access.
AP Priority	Implement the AP access control based on the priority.
AC Cluster	Implement AC redundancy by using the AC cluster to reduce the AC single-point failure and improve availability of the wireless network.
AC Hot Backup	Set up the hot standby connection to ensure that the AP can set up two CAPWAP tunnels.
WLAN Configuration	Configure a WLAN and deploy the WLAN on APs to provide network services for wireless users.
AP Backup	Configure the AP backup function to improve availability of the wireless network.
AC Virtualization	Virtualize one AC into multiple ACs through permission control.
AP Virtualization	Virtualize an AP into multiple APs to be managed by different ACs.
Default SSID Configuration	Configure the default SSID of an AP. When no tunnel is available, the AP uses the default SSID to provide the WLAN access service.

1.3.1 Configuration of AC Authorization Key

The AC authorization key is a license activation key of an earlier version system, and used to control the upper limit of APs supported by an AC.

Working Principle

The license activation key is used to control the upper limit of APs supported by an AC. You can use a command to configure or add a valid license. The input license must be valid, effective, and applicable to the local device. If the upper limit of APs

supported by the AC is reached, no new license can be configured or added. You can also inactivate a license using the **no set license** *activation-key* command.

1.3.2 Configuration of AC Parameters

AC parameters include the AC name, Trap message control, and AC network access server (NAS) ID.

Working Principle

Configuration of AC parameters does not involve any working principle.

1.3.3 Configuration of AP Parameters

AP parameters include the AP name, Telnet user name and password, and periodical statistics report interval.

Working Principle

The AC configures AP parameters by pushing CAPWAP packets to an AP.

1.3.4 Configuration of AP Behaviors

AP behaviors include daily scheduled restart of an AP, restoration of AP factory settings, and AP reset.

Working Principle

Configuration of AP behaviors is implemented by pushing CAPWAP packets to an AP. The AP performs the related behaviors based on the configuration pushed by the AC.

1.3.5 AP Group Management

The AC manages APs through the AP group. All the APs in an AP group can be configured through the AP group, which reduces the configuration workload. Configurations of the AP group take effect on all the APs in the group. For the same configuration, if both the AP-based configurations and the AP-group-based configurations exist, the AP-based configurations prevail.

Working Principle

The system automatically creates a default AP group, which is named "default**"**. By default, APs are added to the default group. You can create AP groups and add APs to these groups to manage APs by group.

1.3.6 AP Quantity Limit

The maximum number of APs that can be connected to an AC is configured to limit the maximum AP load of the AC, thus avoiding overload of the AC.

Working Principle

When the number of APs connected to the AC reaches the maximum number, no more APs can access the AC.

For the WALL-AP product series supplied by Ruijie Network, each device is treated as 0.5 device when the maximum number of APs that can be connected to an AC is calculated. That is, the maximum number of WALL-APs that can be connected to an AC is twice the number of APs supported by the AC.

1.3.7 AP Compliance Check

The AP compliance check is also called AP access control based on the bound MAC address. If the AP compliance check is enabled, only APs with some specified MAC addresses are allowed to access the AC. This prevents access of unwanted APs and enhances security of the wireless network.

Working Principle

An AP is allowed to access the AC only when the AP configuration that is bound with the MAC address of this AP exists on the AC; otherwise, access of the AP to the AC is denied. To prevent binding MAC addresses with a large number of AP configurations, the MAC addresses of currently online APs are automatically bound when the AP compliance check is enabled. In addition, MAC addresses can be bound with specified AP configurations.

1.3.8 AP Access Authentication

AP access authentication can be implemented based on the serial number, password, or certificate. With the AP access authentication function, only authorized APs can access the AC.

Working Principle

When an AP sends an access request to the AC and uploads the authentication information, the AC verifies the authentication information. Only the AP that is successfully authenticated can access the AC.

1.3.9 AP Priority

The AP priority function is an advanced version of the AP quantity limit function. With this function, when the current number of APs connected to the AC reaches the upper limit, if a high-priority AP sends an access request, the AC proactively forces a low-priority AP to go offline and allows the access of the high-priority AP.

Working Principle

When an AP sends an access request, the current number of APs connected to the AC reaches the upper limit, and the AP priority function is enabled, the AC first compares the priorities. If the priority of an online AP is lower than the requesting AP, the AC forces a low-priority AP to go offline and allows the access of the high-priority AP.

1.3.10 AC Cluster

On the one hand, the AC cluster function enhances reliability of the AC cluster. On the other hand, this function controls the home AC of APs in stable conditions based on the priority to facilitate AP management.

Working Principle

See the CAPWAP protocol in RFC5415.

1.3.11 AC Hot Backup

The AC hot backup function is a dual-host hot standby function. It enables switchover of the CAPWAP tunnels between ACs and APs within several milliseconds when an AC is unreachable or faulty, thus ensuring uninterrupted services for associated STAs to the maximum extent.

Working Principle

Two tunnels are set up between an AP and two ACs, and one tunnel works in active mode, and the other works in standby mode. The AC corresponding to the active tunnel serves as the active device that processes all services and transfers the service status information to the standby device for backup purpose. The standby device does not process services, and only backs up the service data. If the active AC is faulty, the standby AC takes over all services.

For details about AC hot standby, see "Configuring WLAN Hot Standby".

1.3.12 WLAN Configuration

Create and deploy a WLAN on an AP so that the AP can provide the WLAN access service for external entities.

Working Principle

The WLAN created on the AC is used for WLAN parameter configuration. The WLAN deployment information and parameters are pushed through the packets defined in the CAPWAP protocol.

1.3.13 AP Backup

The AP backup function is used to back up radio signals transmitted by APs that are physically adjacent with each other, have overlapped coverage, and transmit different radio signals. When an AP that transmits important radio signals is faulty, one or more standby APs transmit radio signals of the faulty AP to replace the faulty AP, thus ensuring stability of radio signals transmitted by devices supplied by Ruijie Networks. This function is generally used in special scenarios. For example, in the zero roaming scenario of the medial industry, the AP4210 with a wide coverage is an important AP, and the APD-M within the coverage of the AP4210serves as a standby AP of the AP4210.

Working Principle

An AP backup group is created on the AC. In this AP backup group, one AP is selected as the active AP, and other APs are standby APs. When the active AP is faulty and goes offline, the WLAN configuration of the active AP is sent to all the standby APs in the group so that the standby APs can transmit radio signals of the active AP.

1.3.14 AC Virtualization

AC virtualization function is used to virtualize one AC into multiple ACs through permission control. Currently, AC virtualization function takes effect only to web management. Users can log in to the web management page using different administrator accounts to check and configure different WLANs, AP groups, and APs. In addition, administrators can back up information of each other. When multiple administrators share the same role, these administrators have the same permissions. When one administrator cannot perform operations due to absence or other causes, another administrator can log in to the web management page using his or her own account and perform the operations. This ensures account security.

Working Principle

A super administrator can create different roles on the AC or by logging in to the web management page, associate administrators with different roles, and assign WLANs, AP groups, and APs to the roles. When an administrator logs in to the web management page, the administrator can only check and configure the corresponding WLANs, AP groups, and APs (STAs). This ensures that different roles manage the same AC at the same time but do not interfere with each other, achieving the effect of virtualizing one AC into multiple ACs.

1.3.15 AP Virtualization

The AP virtualization function virtualizes one AP into multiple APs. Each virtual AP establishes a connection to an AC (not in the hot backup state), and these virtual APs share physical resources of the AP. Each AC can deliver its own configurations and configure its own wireless signals to manage the AP. When an STA receives signals released by an AC, the AP serving the STA reports the corresponding data to the AC. As the data channels used by the virtual APs to report data to the ACs are different and the virtual APs are not accessible to each other, the data security is improved. In addition, as the APs are controlled by multiple ACs, the AC single point of failure (SPOF) will not occur and the AP stability is improved.

Working Principle

Create an AP virtualization template on the active AC and apply the template to an AP, an AP group, or all APs. In this case, the AP establishes connections to other ACs according to configurations of the AP virtualization template and the connected ACs can deliver their own configurations to the AP.

1.3.16 Default SSID Configuration

Configure an SSID for a fit AP to provide the WLAN access service when no CAPWAP tunnel is established.

Working Principle

The AC configures a default SSID for the AP. When the AP restarts or the tunnel is torn down, the AP uses the SSID to provide the WLAN access service.

1.4 Configuration

Configuration	Description and Command	
Configuring the AC Authorization Key	⚠ (Optional) To increase the number of APs supported by an AC, purchase and install a new license.	
	set license	Configures the license activation key.
	license-idle-timeout	Configures the shared aging time of a license.
Configuring an AC Name	⚠ (Optional) A meaningful name can be configured for the AC to facilitate management.	
	ac-name	Configures the name of the local AC.

Configuration	Description and Command	
Configuring the Trap Message Control Function	(Optional) It is used to enable sending of Trap messages. Network operation and maintenance (O&M) can be implemented based on the received Trap messages.	
	acctrl-trap	Configures whether the AC sends specified Trap messages.
Configuring the NAS ID of an AC	(Optional) By default, the NAS ID is the MAC address of the AC in dotted decimal notation.	
	nas-id	Configures the NAS ID of the AC in AC configuration mode.
Creating an AP Configuration	(Optional) It is used to create an AP configuration to configure a specified AP.	
	ap-config	Adds an AP configuration, or enter the AP configuration mode.
Creating an AP Group	(Optional) In AP group configuration mode, this command takes effect on all the online APs in the AP group.	
	ap-group	Adds an AP group configuration, or enters the AP group configuration mode.
Configuring the AP Group of an AP	(Optional) It is used to configure the AP group of a specified AP in AP configuration mode. By default, an AP belongs to the default group.	
	ap-group	Configures the AP group of an AP.
Configuring an AP Name	(Optional) A new name can be configured for an AP according to requirements.	
	ap-name	Configures an AP name.
Binding an MAC Address with an AP Configuration	(Optional) It is used to bind an MAC address with an AP configuration so that the AP configuration can take effect on the AP with the MAC address.	
	ap-mac	Binds an MAC address with an AP configuration.
Configuring the User Name and Password of an AP	(Optional) It is used to modify the Telnet user name and password of an AP according to requirements.	
	credential	Configures the user name and password of an AP.
Configuring the Interval at Which the AP Reports Statistics	(Optional) According to the standard, the AP reports statistics at the interval of 120s by default. The interval can be configured according to requirements.	
	statistics-timer	Configures the interval at which the AP reports statistics.
Configuring the Daily Scheduled Restart Time for an AP	(Optional) The daily scheduled restart function can be configured for an AP to prevent the AP from working for a long time.	
	reload at	Configures the daily scheduled restart time for an AP.
	(Optional) It is used to restore factory settings of an AP.	

Configuration	Description and Command	
Restoring Factory Settings of a Specified AP	**factory-reset**	Restores factory settings of a specified AP.
Resetting an AP	(Optional) It is used to reset an AP.	
	reset	Resets an AP.
Configuring the AP Quantity Limit	(Optional) The maximum number of APs connected to the AC can be configured according to requirements to reduce the maximum load of the AC.	
	wtp-limit	Configures the maximum number of APs that can be connected to the AC.
Configuring the AP Compliance Check	(Optional) The AP compliance check can be enabled to allow the access of only APs with the bound MAC addresses, thus effectively controlling the access of APs.	
	bind-ap-mac	Enables or disables the AP compliance check in AC configuration mode.
Configuring AP Access Authentication	(Optional) AP access authentication can be configured so that only authorized APs can access the AC, which enhances security of the wireless network.	
	ap-auth enable	Enables or disables the AP access authentication function of the AC in AC configuration mode.
	ap-auth serial-update	Updates authentication serial numbers for all online APs in AC configuration mode.
	ap-auth	Configures the access authentication information of an AP in AP configuration mode.
Configuring the AP Priority	(Optional) This command is available in both the AC and AP configuration modes.	
	ap-priority	Enables or disables the AP access priority function of the AC in AC configuration mode.
	priority	Configures the failover priority of a specified AP in AP configuration mode.
Configuring the AC Cluster Function	(Optional) It is used to configure the redundancy ACs of a specified AP or all APs in AP configuration mode.	
	primary-base	Configures the primary AC of an AP.
	secondary-base	Configures the secondary AC of an AP.
	tertiary-base	Configures the tertiary AC of an AP.
	backup-controller-primary	Configures the fourth AC of an AP.
	backup-controller-secondary	Configures the fifth AC of an AP.
	backup-controller-tertiary	Configures the sixth AC of an AP.
	(Optional) It is used to adjust the hot backup connection parameters.	

Configuration	Description and Command	
Configuring the AC Hot Backup Function	**ap-group**	Binds an AP group.
	peer-ip	Configures the peer IP address.
	peer-ipv6	Configures the peer IPv6 address.
	peer-ipv6 enable	Enables the peer IPv6.
Configuring the AP System Log Information	(Optional) It is used to configure the log information of a specified AP or all APs in AP configuration mode.	
	logging on	Enables or disables the function of displaying system logs.
	logging server	Configures the address of the system logging server.
Creating a WLAN	(Optional) A WLAN must be created before it can be deployed.	
	wlan-config	Creates a WLAN, or enters the WLAN configuration mode.
Deploying a WLAN	(Optional) It is used to configure the WLAN-VLAN mapping of a specified AP group and deploy the WLAN on all the APs in the AP group.	
	interface-mapping	Configures the WLAN-VLAN mapping of a specified AP group in AP group configuration mode.
Enabling or Disabling WLAN SSID Broadcasting	(Optional) SSID broadcasting is disabled by default.	
	enable-broad-ssid	Enables or disables SSID broadcasting of a specified WLAN in WLAN configuration mode.
Configuring the NAS ID of WLAN Users	(Optional) The NAS ID is a null string by default.	
	nas-id	Configures the NAS ID of a specified WLAN user.
Configuring the Fit or Fat AP Mode	(Optional) The AP mode can be switched between the fit AP mode and the fat AP mode according to requirements.	
	switch2fat	Switches the mode of a specified AP to the fat AP mode in AC configuration mode on the AC device.
	ap-mode	Configures the fit or fat AP mode in global configuration mode.
Configuring the WLAN SSID Name	(Optional) A new SSID can be configured for the WLAN according to requirements.	
	ssid	Modifies the SSID name of the WLAN in WLAN configuration mode.
	ssid-code	Configures the coded character set for the SSID.
Configuring the AP Backup Function	(Optional) It is used to improve availability of the wireless network.	
	ap-backup group	Creates an AP backup group in AC configuration mode.
	ap-backup-group	Binds an AP backup group.

Configuration	Description and Command	
Configuring the AC Virtualization Function	(Optional) It is used to assign wireless permissions and virtualize one AC into multiple ACs.	
	permit enable	Configures whether to enable AC virtualization
	master-group	Adds a role and enters the role configuration mode.
	master-group (AP configuration mode)	Assigns an AP to a specific role in AP configuration mode.
	master-group (AP group configuration mode)	Assigns an AP group to a specific role in AP group configuration mode.
	master-group (WLAN configuration mode)	Assigns a WLAN to a specific role in WLAN configuration mode.
	webmaster (role configuration mode)	Adds/Deletes an administrator in role configuration mode.
Configuring the AP Virtualization Function	(Optional) It is used to enable multiple ACs to manage the same AP.	
	virtual-ap	Creates an AP virtualization template in global configuration mode.
	ac-ip	Configures the IP address of the AC to which a virtual AP is to be connected.
	wlan-capacity	Configures the number of WLANs supported by a virtual AP.
	sta-capacity	Configures the number of STAs supported by a virtual AP.
	link-interface	Configures the uplink interface used by a virtual AP to connect to an AC.
	virtual-ap	Configures a virtual AP in single AP, AP group, and all-AP configuration modes.
	ap-idle-timeout	Configures the duration for a virtual AP to continue service provision after the connection between the AP and active AC is down.
Configuring the Default SSID	**offline-ssid**	Configures the WLAN access signal provided when an AP is offline.

1.4.1 Configuring the AC Authorization Key

Configuration Effect

- Increase the number of APs supported by an AC.

Notes

- A configured license takes effect permanently. That is, the license never expires. Once you configure the license, you are assigned to use the function permanently.

- The license takes effect as soon as it is configured on a device, and restart of the device is not necessary.
- Multiple licenses can be configured on the same AC device. That is, the maximum number of APs supported by an AC is equal to the sum of the AP quantities authorized by the licenses, but cannot exceed the capacity of the AC.
- After being inactivated, the license cannot be installed on the device again. But you can apply for a new license for another device using this license, the old SN, the deactivation key and a new SN.
- After you inactivate a license, the number of APs allowed to be online reduces immediately. The APs that are already online are not affected.
- This command is used to import the activation key of the earlier-version license system. A new license is installed by using the license file installation command. For details, see "Software Authorization Management."

Configuration Steps

- Optional. To increase the number of APs supported by an AC, purchase and install a new license.
- The license activation key is not installed by default.
- You can run the **set license** *activation-key* command in global configuration mode to import the activation key of the earlier-version license system.
- You can run the **no set license** *activation-key* command in global configuration mode to inactivate an existing activation key.

Command	**set license***activation-key*
Parameter Description	*activation-key*: indicates the license activation key to be configured. The format of the license key depends on the actual situations, for example, AAAA-BBBB-CCCC-DDDD-EEEE-FFFF-GGGG-HHHH.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	A license is applicable to only the device that you specify when applying for a license, and does not take effect on other devices. The same license cannot be configured for multiple times on one device.

Command	**no set license** *activation-key*
Parameter Description	*activation-key*: indicates the license key to be inactivated. The format of the license key depends on the actual situations, for example, AAAA-BBBB-CCCC-DDDD-EEEE-FFFF-GGGG-HHHH.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	After being inactivated, the license cannot be installed on the device again. But you can apply for a new license for another device using this license, the old SN, the deactivation key and a new SN.

Command	**license-idle-timeout** *timeout*
Parameter Description	*timeout*: Indicates the shared aging time (in the unit of hour) of the license in a license sharing network after the AC stops using the license. The value ranges from **1** to **336** (14 days).

Defaults	168 (7 days)
Command Mode	AC configuration mode
Usage Guide	This command applies to the license sharing scenarios, for example, AC virtualization scenarios.

Verification

- Run the **show license all-license** command to check the license information and determine whether the configuration is successful.
- **show license unbind-code command** to check the inactivated license.

Configuration Example

Configuring the License Activation Key

Configuration Steps	• Add a license.
AC	`Ruijie#config terminal` `Ruijie(config)#set license4A3F-16AB-330C-B254-42C4-E18A-24F3-15CA`
Verification	Run the **show license all-license** command to check the current license.
AC	`Ruijie(config)#show license all-license` `Searching license in the system...` `There's no license installed in the system.` `-----------------------------------------` `There are some old version licenses:` `1. 4A3F-16AB-330C-B254-42C4-E18A-24F3-15CA 128`

Inactivating a License

Configuration Steps	• Inactivate a license.
AC	`Ruijie#config terminal` `Ruijie(config)# no set license 4A3F-16AB-330C-B254-42C4-E18A-24F3-15CA` `After unbinding, you can not install the corresponding license again. Are you sure to continue[y/n]:y` `The verification string is: xxxxxxxxxxxx`

Verification	Run the **show license all-license** command to check the inactivated license.
AC	`Ruijie(config)#show license unbind-code` `LICENSE UNBINDING-CODE` `4A3F-16AB-330C-B254-42C4-E18A-24F3-15CA xxxxxxxxxxxxxxxxxxxxxxxxxxxx`

Common Errors

- N/A

1.4.2 Configuring an AC Name

Configuration Effect

- Set the name of an AC to a specified string.

Notes

- The AC name is a string of 1 to 63 characters, and cannot contain any space.

Configuration Steps

- Optional. Run the **ac-name** *ac-name* command in AC configuration mode to configure a new name for an AC.
- Run the **ac-controller** command to enter the AC configuration mode.
- Run the **ac-name** command to configure an AC name in AC configuration mode on an AC device.

Command	**ac-controller**
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**ac-name***ac-name* **no ac-name**
Defaults	The default AC name is Ruijie_Ac_*Last six digits of MAC address*. For example, if the MAC address of an AC is 001a.a916.e7b8, the default name of this AC is Ruijie_Ac_16e7b8.
Parameter Description	*ac-name*: indicates the name of an AC. The name is a string of 1 to 63 characters, and cannot contain any space.
Command Mode	AC configuration mode
Usage Guide	Different names can be configured for different ACs to facilitate management.

Verification

- Run the **show ac-config** command to check the current AC name and determine whether the configuration is successful.

Configuration Example

↘ Configuring the Name of an AC as "Ruijie-AC1"

Configuration Steps	● Enter the AC configuration mode. ● Configure an AC name. ● Use the **no** form of this command to restore the default AC name.
AC	`Ruijie(config)#ac-controller` `Ruijie(config-ac)#` `Ruijie(config-ac)#ac-name Ruijie-AC1` `Ruijie(config)#ac-controller` `Ruijie(config-ac)#no ac-name`
Verification	Run the **show ac-config** command to check the current AC name.
AC	`Ruijie#show ac-config` `ac_name :Ruijie-AC1`

Common Errors

- N/A

1.4.3 Configuring the Trap Message Control Function

Configuration Effect

- The AC sends the following types of Trap messages: CAPWAP tunnel up/down information, failures to add APs to the AC,CAPWAP tunnel packet decryption failures, upgrade failures, time synchronization failures, and STA online/offline information.
- By default, all the preceding Trap messages are not sent. You can run the **acctrl-trap** command in AC configuration mode to enable sending of specified Trap messages.

Notes

- N/A

Configuration Steps

- Optional. On the AC device, enter the AC configuration mode and run the **acctrl-trap** command to configure the Trap message control function.

Command	**acctrl-trap**[**acap-updown-ctrl** | **acap-joinfail-ctrl** | **acap-decryeroreport-ctrl** | **acap-imageupdt-ctrl** | **acap-timestamp-ctrl** | **acsta-oper-ctrl**]
Parameter Description	**acap-updown-ctrl**: Determines whether to send the Trap messages that contain the CAPWAP tunnel up/down information. **acap-joinfail-ctrl**: Determines whether to send the Trap messages that contain information about failures of adding APs to the AC. **acap-decryeroreport-ctrl**: Determines whether to send the Trap messages that contain information about CAPWAP tunnel packet decryption failures. **acap-imageupdt-ctrl**: Determines whether to send the Trap messages that contain information about the **bin** file upgrade failures of the AP. **acap-timestamp-ctrl**: Determines whether to send the Trap messages that contain the time synchronization information. **acsta-oper-ctrl**: Determines whether to send the Trap messages that contain the STA online/offline information.
Defaults	By default, all types of Trap messages are not sent. You can run the **acctrl-trap** command in AC configuration mode to enable sending of these messages.
Command Mode	AC configuration mode
Usage Guide	This command is used to control sending of Trap messages on the AC.

Verification

- Run the **show ac-config** command to check the sending status of various types of Trap messages.

Configuration Example

↘ Enabling the AC to Send the Trap Messages That Contain Information About Failures to Add APs to the AC

Configuration Steps	• Enter the AC configuration mode. • Enable the AC to send the Trap messages that contain information about failures to add APs to the AC. • Use the **no** form of this command to restore the default setting.
AC	`Ruijie(config)#ac-controller` `Ruijie(config-ac)#acctrl-trap acap-joinfail-ctrl` `Ruijie(config)#ac-controller` `Ruijie(config-ac)#no acctrl-trap acap-joinfail-ctrl`
Verification	Run the **show ac-config** command to check the sending status of various types of Trap messages.

AC	Ruijie#show ac-config acctrl-trap acap-updown-ctrl :Disable acctrl-trap acap-joinfail-ctrl :Enable acctrl-trap acap-decryeroreport-ctrl :Disable acctrl-trap acap-imageupdt-ctrl :Disable acctrl-trap acap-timestamp-ctrl :Disable acctrl-trap acsta-oper-ctrl :Disable

Common Errors

- N/A

1.4.4 Configuring the NAS ID of an AC

Configuration Effect

- On the WLAN, the NAS IDs identify different hot spot areas. By default, the NAS ID of an AC is the MAC address of the AC in dotted decimal notation.

Notes

- N/A

Configuration Steps

- Optional.
- On the AC device, enter the AC configuration mode and run the **nas-id** command to configure the NAS ID.

Command	**nas-id** *ac-nas-id* **no nas-id**
Parameter Description	N/A
Defaults	MAC address of the AC in dotted decimal notation
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to check the AC configuration.

Configuration Example

Setting the NAS ID of the AC to 123456789

Configuration Steps	● Enter the AC configuration mode. ● Configure the NAS ID.
AC	`Ruijie(config)# ac-controller` `Ruijie(config-ac)#nas-id123456789`
Verification	Run the **show running** command to check the AC configuration.
AC	`Ruijie#show running` `!` `ac-controller` ` nas-id 123456789` `!`

Common Errors

- N/A

1.4.5 Creating an AP Configuration

Configuration Effect

- Create an AP configuration with the specified name, and enter the AP configuration mode.
- If the AP configuration corresponding to a name already exists, you can directly enter the AP configuration mode after the command is executed.
- The *ap-name* parameter indicates the name of the AP configuration. When an AP gets online, the AP name uploaded by the AP is matched with the AP configuration name to determine the mapping relationship between the AP device and AP configuration.

Notes

- N/A

Configuration Steps

- Optional.
- On the AC device, enter the global configuration mode and run the **ap-config***ap-name* command to create an AP configuration.

Command	**ap-config** *ap-name*
Parameter Description	*ap-name*: indicates the name of the AP configuration.

Defaults	No AP configuration is created by default.
Command Mode	Global configuration mode
Usage Guide	1. You can run the **ap-config all** command to enter the all-AP configuration mode. Configurations made in this mode take effect on all APs associated with the current AC. Configurations made in AP configuration mode take precedence over configurations made in all-AP configuration mode. If configurations (non-default settings) exist in AP configuration mode (entered by running the **ap-config** *ap-name* command), such configurations are preferentially used; otherwise, configurations made in all-AP configuration mode (entered by running the **ap-config all** command) are used. 2. You can run the **no ap-config** *ap-name* command to delete a specified AP configuration. If the AP corresponding to this configuration is already online, the AP will be forced offline and then go online again after the configuration is deleted. 3. You can run the **no ap-config all** command to delete configurations of all offline APs on the current AC.

Verification

- Run the **show ap-config running** *ap-name* command to check the configurations of the AP.

Configuration Example

Creating an AP Configuration Named "Ruijie_AP"

Configuration Steps	• Create an AP configuration named "Ruijie_AP".
AC	`Ruijie(config)#ap-config Ruijie_AP` `You are going to config AP(Ruijie_AP), which is not on line now.` `Ruijie(config-ap)#`
Verification	Run the **show ap-config running** command to check the current configurations of the AP.
AC	`Ruijie#show ap-config running Ruijie_AP` `!` `ap-config Ruijie_AP` `!`

Common Errors

- N/A

1.4.6 Creating an AP Group

Configuration Effect

- The AC manages APs through the AP group. All the APs in an AP group can be configured through the AP group, which reduces the configuration workload. Configurations of the AP group take effect on all the APs in the group.

Notes

- The default group is created automatically by the system, and cannot be deleted.
- When an AP group is deleted, APs of this group are automatically moved to the default group.
- Configurations made in different configuration modes take effect in the following sequence: ap-config ap-name>ap-group>ap-config all.

Configuration Steps

- Optional.
- On the AC device, enter the global configuration mode, and run the **ap-group** *ap-group-name* command to create an AP group.

Command	**ap-group** *ap-group-name* **no ap-group** *ap-group-name*
Parameter Description	***ap-group-name***: indicates the name of an AP group.
Defaults	An AP group named "default" is automatically created by default after the system is started. This group can neither be created nor deleted.
Command Mode	Global configuration mode
Usage Guide	When the **no** form of the command is used to delete an AP group, APs of this group are automatically moved to the default group.

Verification

- Run the **show running** command to check configurations of all AP groups.

Configuration Example

↘ Creating an AP Group Named "APG-1"

Configuration Steps	● In global configuration mode, run the **ap-group** command to create an AP group.
AC	`Ruijie(config)#ap-group APG-1` `Ruijie(config-ap-group)#`
Verification	Run the **show running** command to check whether the AP group named "APG-1" exists.

AC	Ruijie#show running ! ap-group APG-1 !

Common Errors

- N/A

1.4.7 Configuring the AP Group of an AP

Configuration Effect

- An AP group must already exist if you want to add an AP to this group.
- By default, APs belong to the default AP group, that is, the AP group named "default".
- APs inherit all configurations of the AP group to which APs belong. If the same configuration exists in the specified AP configurations (**ap-config***ap-name*), all AP configurations (**ap-config all**), and AP group configurations, the configurations take effect in the following sequence: specified AP configurations > AP group configurations > all AP configurations. Therefore, if the AP group of an AP changes, AP group configurations inherited by this AP change as well.

Notes

- N/A

Configuration Steps

- Optional.
- Run the **ap-config** command to create an AP group or enter the AP configuration mode.
- On the AC device, enter the AP configuration mode and run the **ap-group** command to configure the AP group of an AP.

Command	**ap-config***ap-name*
Parameter Description	*ap-name***:** indicates the name of the AP configuration.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**ap-group** *ap-group-name* **no ap-group**
Parameter Description	*ap-group-name***:** indicates the name of an AP group.

Defaults	By default, APs are automatically added to the default group.
Command Mode	AP configuration mode
Usage Guide	When an AP group is deleted, APs of this group are automatically moved to the default group.

Verification

- Run the **show ap-config running** command to check the current configurations of the AP.

Configuration Example

Configuring the AP Group to Which Ruijie-AP1 Belongs

Configuration Steps	• Create an AP group named "apg-1". • Enter the AP configuration mode. • Use the **no** form of this command to restore the default AP group, that is, the AP group named "default".
AC	`Ruijie(config)#ap-group apg1` `Ruijie(config-ap-group)#` `Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#` `Ruijie(config-ap)#ap-group apg-1` `Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ac)#no ap-group`
Verification	Run the **show ap-config running** command to check the current configurations of the AP.
AC	`Ruijie(config)#show ap-config running Ruijie-AP1` `!` `ap-config Ruijie-AP1` `ap-group apg-1` `!`

Common Errors

- N/A

1.4.8 Configuring an AP Name

Configuration Effect

Configure an AP name on the AC.

- If the AP is currently online, the configuration of the AP name takes effect immediately. In addition, the AP name in the specified AP configuration mode (that is, the string next to **ap-config**) is immediately replaced by the new name.
- If the AP is currently offline, the configuration of the AP name takes effect after the AP goes online, and the AP name in the AP configuration mode is not replaced by the new name until the AP goes online.
- After the AP name is configured, you can continue to configure this AP without exiting from the AP configuration mode.
- If the corresponding AP is online, the **no** form of the command is not supported.
- If the corresponding AP is online, the **no** form of the command can be used to delete the AP name configuration that is currently not effective.
- If the new name is already in use, the configuration fails.

Configure an AP name on the AP.

- If the CAPWAP connection is not set up, the AP name is configured directly.
- If the CAPWAP connection is set up, the AP name is configured first. Then the CAPWAP tunnel will be torn down and a connection will be set up again. If the AP name is already configured on the AC or configured offline, this AP name prevails.

Notes

- The AP name is a string of 1 to 63 characters, and cannot contain any space.
- The AP name cannot be configured as "all" or "AP".
- Avoid configuring the same AP name for different offline APs. If the same AP name is configured for different offline APs, the new name takes effect on the AP that goes online first, and the APs that go online later still use the original names.
- Configuring the AP name on the AP only takes effect in fit AP mode.

Configuration Steps

- Optional. You can run the **ap-name** *ap-name* command in AP configuration mode to configure an AP name. It is recommended that a meaningful AP name be configured to facilitate management.
- On the AC device, enter the AP configuration mode and run the **ap-group** command to configure an AP name.

Command	**ap-name** *name*
Parameter Description	*name*: indicates the name of an AP. The name cannot contain any space.
Defaults	The AC uses the name uploaded by the AP as the AP name. In the factory settings, the MAC address is often used as the name of an AP.
Command Mode	AP configuration mode
Usage Guide	1. Do not configure the AP name as "all" or "AP". 2. After the command is executed, the command mode of an online AP is the AP command mode with the new AP name, and you can continue to configure other properties of the AP without existing from the command mode. The command mode of an offline AP remains unchanged.

- On the AP device, enter the global configuration mode and run the **ap-name** command to configure an AP name.

Command	**ap-name** *name*
Parameter Description	*name*: indicates the name of an AP. The name cannot contain any space.
Defaults	The default name is AP.
Command Mode	Global configuration mode
Usage Guide	1. Do not configure the AP name as "all". 2. After this command is executed, the CAPWAP tunnel will be set up again.

Verification

- Run the **show ap-config running** command to check the current configurations of the AP.
- Run the **show ap-config summary** command to check whether the name of the online AP is the new name.
- Run the **show running-config** command to check the AP configuration.

Configuration Example

Changing the Name of an Online AP from "Ruijie-AC1" to "Ruijie-AC2"

Configuration Steps	• Enter the AP configuration mode. • Configure the name of an AP.
AC	`Ruijie(config)#ap-config Ruijie-AC1` `Ruijie(config-ap)#ap-name Ruijie-AC2`
Verification	• Run the **show ap-config running** command to check the current configurations of the AP. • Run the **show ap-config summary** command to query the current name of the online AP.
AC	`Ruijie#show ap-config running` `!` `ap-config Ruijie-AC2` `!` `Ruijie#show ap-config summary` `========= show ap status =========` `Radio: Radio ID or Band: 2.4G = 1#, 5G = 2#` `E = enabled, D = disabled, N = Not exist` `Current Sta number/Max Sta number supported` `Channel: * = Global`

```
      Power Level = Percent

Online AP number: 0

Offline AP number: 1

AP Name                                 IP Address      Mac Address    Radio 1
Radio 2           Up/Off time   State
---------------------------------------- --------------- -------------- -----
-------------- ------------------ ------------- -----

ap1                                  10.0.20.15     00d0.f822.33b0 N   -/-     -
- N   -/-     -     -    0:00:16:03 Quit
```

Changing the Name of an Offline AP from "Ruijie-AC1" to "Ruijie-AC2"

Configuration Steps	● Enter the AP configuration mode. ● Configure the name of an AP.
AC	`Ruijie(config)#ap-config Ruijie-AC1` `Ruijie(config-ap)#ap-name Ruijie-AC2`
Verification	Run the **show ap-config running** command to check the current configurations of the AP.
AC	`Ruijie#show ap-config running` `!` `ap-config Ruijie-AC1` `  ap-name Ruijie-AC2` `!`

Deleting the Name Configuration of an Offline AP Ruijie-AC1

Configuration Steps	● Enter the AP configuration mode. ● Delete the name configuration of an offline AP Ruijie-AC1.
AC	`Ruijie(config)#ap-config Ruijie-AC1` `Ruijie(config-ap)#no ap-name`
Verification	Run the **show ap-config running** command to check the current configurations of the AP.
AC	`Ruijie#show ap-config running` `!`

	ap-config Ruijie-AC1 !

Configuring the Name of an AP as Ruijie-AP1.

Configuration Steps	● Enter the global configuration mode. ● Configure the AP name.
AP	Ruijie(config)#ap-name Ruijie-AP1
Verification	Run the **show ap-config running** command to check the current configurations of the AP.
AP	Ruijie#show running-config Building configuration... Current configuration: 1592 bytes version 11.1(5)B0 privilege exec all level 1 debug privilege exec all level 1 show privilege exec all level 1 terminal privilege exec all level 1 undebug ap-name Ruijie-AP1 fair-schedule !

Common Errors

- N/A

1.4.9 Binding an MAC Address with an AP Configuration

Configuration Effect

- In AP configuration mode, run the **ap-mac** command to bind an MAC address with an AP configuration so that the AP configuration takes effect only on the AP with the MAC address.
- Generally, when an AP goes online, it determines the configuration to be used based on the mapping between the AP name and the AP configuration name. MAC address binding is a stronger binding relationship than name mapping, and takes precedence over name mapping. Therefore, when an AP goes online, the AP uses the configuration so far as the MAC address bound with the AP configuration is the same as the MAC address of the AP.
- If no MAC address is bound with an AP configuration, the MAC address is automatically bound when the corresponding AP goes online. This bounding relationship still takes effect when the AP goes offline. That is, the binding configuration will be automatically generated when the AP goes online.

- MAC address binding is also used for the AC access control function configured by using the **bind-ap-mac** command. For details, see the configuration description of this command.
- You can bind a specified MAC address only with the configuration of an offline AP.
- In the hot standby environment, you can ensure consistency of configurations between two ACs by binding the MAC addresses with AP configurations.

Notes

- You can bind a specified MAC address only with the configuration of an offline AP.

Configuration Steps

- Optional.
- On the AC device, enter the AP configuration mode and run the **ap-mac** command to bind an MAC Address with an AP configuration.

Command	**ap-mac** *ap-mac-address* **no ap-mac**
Parameter Description	*ap-mac-address*: indicates the MAC address that is bound.
Defaults	No AP configuration is bound with the MAC address by default. You can bind the MAC address of an AP with the AP configuration to forcibly apply this AP configuration on the AP with the MAC address.
Command Mode	AP configuration mode
Usage Guide	● The **ap-mac** *ap-mac-address* command is applicable to configurations of offline APs. You can use this command to specify the MAC address of an offline AP so that the AP configuration can be located directly based on the MAC address after the AP goes online. ● The **no ap-mac** command is applicable to all AP configurations.

Verification

- Run the **show ap-config running** command to check the MAC address binding of the current AP.

Configuration Example

↘ Binding the Offline AP Ruijie-AP1 with the MAC Address 001a.a979.1234

Configuration Steps	● Enter the AP configuration mode. ● The **no** form of the command is used to delete the MAC address binding.
AC	`Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#ap-mac 001a.a979.1234` `Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ac)#no ap-mac`

Verification	Run the **show ap-config running** command to check the current configurations of the AP.
AC	`Ruijie(config)#show ap-config running Ruijie-AP1` `!` `ap-config Ruijie-AP1` `  ap-mac 001a.a979.1234` `!`

Common Errors

- N/A

1.4.10 Configuring the User Name and Password of an AP

Configuration Effect

- Authorized users may directly login to an AP and modify the AP configuration through Telnet, which affects normal running of the WLAN. To prevent this problem, you can configure the Telnet user name and password of a specified AP.
- The **credential** command can be used in **ap-config** *ap-name*, **ap-group**, or **ap-config all** configuration mode. Configurations made by using the **credential** command take effect in the following sequence: **ap-config** *ap-name*>**ap-group**>**ap-config all**.

Notes

- N/A

Configuration Steps

- Optional: You can run the **credential** *user-name password* command to configure a new Telnet user name and password in AP configuration mode to enhance security.
- On the AC device, enter the AP or AP group configuration mode and run the **credential** command for configuration.

Command	**credential** *user-name password* **nocredential**
Parameter Description	*user-name*: indicates the user name. A user name cannot contain any space. *password*: indicates the password. A password cannot contain any space.
Defaults	The AC device uses factory settings of the Telnet user name and password of an AP. You can modify the Telnet user name and password of an AP according to requirements to facilitate management.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Verification

- Run the **show ap-config running** or **show running** command to check the configurations.

Configuration Example

Configuring the User Name and Password of Ruijie-AP1

Configuration Steps	● Configure the user name and password of Ruijie-AP1. ● Use the **no** form of the command to delete the configuration of the user name and password of the AP. (After the deletion, the default user name and password are restored on the AP.)
AC	`Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#credential user pass` `Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ac)#no credential`
Verification	Run the **show ap-config running** command to check the current configurations of the AP.
AC	`Ruijie(config)#show ap-config running Ruijie-AP1` `!` `ap-config Ruijie-AP1` `  credential user pass` `!`

Common Errors

- N/A

1.4.11 Configuring the Interval at Which the AP Reports Statistics

Configuration Effect

- Run the **statistics-timer** command to configure the interval at which the AP reports statistics.

Notes

- N/A

Configuration Steps

- Optional. You can adjust the interval based on the statistics accuracy requirement and loads on the AC and AP.
- On the AC device, enter the AP or AP group configuration mode and run the **statistics-timer** command for configuration.

Command	**statistics-timer** *timer-interval* **nostatistics-timer**
Parameter Description	*timer-interval*: indicates the interval that the AP reports statistics. The unit is second.
Defaults	120s

Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Verification

- Run the **show ap-config running** command to check the configurations.

Configuration Example

Setting the Interval at Which Ruijie-AP1 Reports Statistics to 300s

Configuration Steps	• Set the interval at which Ruijie-AP1 reports statistics to 300s. • Use the **no** form of the command to restore the default interval at which Ruijie-AP1 reports statistics.
AC	`Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#statistics-timer 300` `Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ac)#no statistics-timer`
Verification	Run the **show ap-config running** command to check the current configurations of the AP.
AC	`Ruijie(config)#show ap-config running Ruijie-AP1` `!` `ap-config Ruijie-AP1` `  statistics-timer 300` `!`

Common Errors

- N/A

1.4.12 Configuring the AP System Log Information

Configuration Effect

- Control displaying of the AP system logs, and set the IP address of the server that records the AP system logs.

Notes

- N/A

Configuration Steps

- Optional.
- Run the **logging on** command to display system logs of a specified AP.

- Run the ***logging server*** *ip-address* ***[udp-port*** *num****]*** command to configure the IP address of the system log server of a specified AP.

Command	**loggingon** **no loggingon**
Parameter Description	N/A
Defaults	The system logs are displayed by default.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Command	**logging server** *ip-address***[udp-port** *num***]** **no logging server** *ip-address*
Parameter Description	*ip-address*: indicates the IP address of the host that receives the log information. num: indicates the ID of the port on the host that receives the log information. This parameter is optional.
Defaults	N/A
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	You can configure at most five log server addresses. The log information will be sent simultaneously to all the configured log servers.

Verification

- Run the **show ap-config running** command to check the configurations.

Configuration Example

Disabling the Function of Displaying System Logs on Ruijie-AP1

Configuration Steps	● Enter the AP configuration mode. ● Disable the function of displaying system logs.
AC	`Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#no logging on`
Verification	Run the **show ap-config running** command to check the current configurations of the AP.
AC	`Ruijie(config)#show ap-config running Ruijie-AP1` `!` `ap-config Ruijie-AP1` `  no logging on` `!`

Configuring the Log Server Address of Ruijie-AP1

Configuration Steps	● Enter the AP configuration mode. ● Set the log server address to 1.1.1.1.
AC	`Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#logging server 1.1.1.1`
Verification	Run the **show ap-config running** command to check the current configurations of the AP.
AC	`Ruijie(config)#show ap-config running Ruijie-AP1` `!` `ap-config Ruijie-AP1` `  logging server 1.1.1.1` `!`

Common Errors

- N/A

1.4.13 Configuring the Daily Scheduled Restart Time for an AP

Configuration Effect

- If APs work too long, the load may be too heavy, affecting the network access quality of users. To prevent this problem, you can configure the daily scheduled restart time for an AP so that the network access quality of users can be ensured every day.

Notes

- N/A

Configuration Steps

- Optional. You can enable the daily scheduled restart function based on the AP load.
- Configure the daily scheduled restart time to prevent APs from working for a long time, enhancing availability of the network.

Command	**reload at***time* **no reload at**
Parameter Description	*time*: indicates the time when the AP is restarted every day. The time is expressed in the format of hh:mm:ss.
Defaults	The daily scheduled restart function of an AP is disabled by default.
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Run the **show ap-config running** command to check the configurations.

Configuration Example

↘ Enabling Ruijie-AP1 to Restart at 1:00:00 Every Day

Configuration Steps	• Enable Ruijie-AP1 to restart at 1:00:00 every day. • Use the **no** form of the command to cancel the scheduled restart configuration.
AC	`Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#reload at 1:00:00` `Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ac)#no reload at`
Verification	Run the **show ap-config running** command to check the current configurations of the AP.
AC	`Ruijie(config)#show ap-config running Ruijie-AP1` `!` `ap-config Ruijie-AP1` `  reload at 1:00:00` `!`

Common Errors

- N/A

1.4.14 Restoring Factory Settings of a Specified AP

Configuration Effect

- Restore factory settings of a specified AP.
- The configuration takes effect only on an online AP.

Notes

- This operation will cause offline and reset of the AP.

Configuration Steps

- Optional. You can restore factory settings of a specified AP according to requirements.
- Restoring AP factory settings is an instant behavior of an AP. This command can restore factory settings of the AP and will trigger reset of the AP.

Command	**factory-reset***ap-name*

Parameter Description	*ap-name*: indicates the name of an AP.
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	This operation will cause reset of the AP.

Verification

- After this command is executed for an online AP, this AP will go offline. After the AP goes online again, run the **show ap-config running** command to check whether factory settings of the AP are restored.

Configuration Example

Restoring Factory Settings of the Online AP Ruijie-AP1

Configuration Steps	• Enter the AC configuration mode. • Restore factory settings of the online AP Ruijie-AP1.
AC	`Ruijie(config)#ac-controller` `Ruijie(config-ac)#factory-reset Ruijie-AP1`
Verification	After this command is executed for an online AP, this AP will go offline. After the AP goes online again, run the **show ap-config running** command to check whether factory settings (null settings) of the AP are restored.

Common Errors

- N/A

1.4.15 Resetting an AP

Configuration Effect

- Reset an online AP.
- Reset all online APs.

Notes

- N/A

Configuration Steps

- Optional. You can reset one or more APs according to requirements.
- If you configure AP reset on the AC, the corresponding AP will reset. You can configure reset of a specified AP or all online APs.

Command	**reset**{ **all** |**single** *ap-name*}

Parameter Description	**all**: indicates that all online APs are reset. **single *ap-name***: indicates that a specified AP is reset.
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- After the configuration is completed, you can view the syslog record on the AC, indicating that the corresponding AP goes offline, and the AP will be reset.

Configuration Example

Resetting Ruijie-AP1

Configuration Steps	• Enter the AC configuration mode. • Reset Ruijie-AP1.
AC	`Ruijie(config)#ac-controller` `Ruijie(config-ac)#` `Ruijie(config-ac)#reset Ruijie-AP1`
Verification	Check whether Ruijie-AP1 is reset, and whether the following syslog record indicating the offline event of the AP can be viewed on the AC.
AC	`%APMG-6-RX_CTRL_MSG: AP(AP_20#3F_S:001a.a912.3456) leave AC.`

Common Errors

- N/A

1.4.16 Configuring the AP Quantity Limit

Configuration Effect

- The number of online APs connected to the AP does not exceed the configured maximum number of APs supported by the AC.

Notes

- The weight of an AP varies according to the AP model. For example, the weight of one WALL-AP is 0.5 and two WALL-APs are treated as one AP. When APs are connected to an AC, the weighted number of APs is calculated based on the weight. This command and the license control the weighted number of APs, instead of the actual number of APs.

Configuration Steps

- Optional. You can configure the AP quantity limit within the capacity range according to requirements.

Command	**wtp-limit** *max-num*
Parameter Description	*max-num*: indicates the maximum number of APs that can be connected to an AC.
Defaults	By default, this number is equal to the number of APs supported by an AC.
Command Mode	AC configuration mode
Usage Guide	This command is used to configure the maximum number of APs connected to an AC. This number cannot exceed the maximum number of APs supported by the AC or the maximum number of APs allowed by the license.

Verification

- Run the **show ac-config** command to check the current AC name and determine whether the configuration is successful.

Configuration Example

Setting the Maximum Number of APs Connected to the AC to 512

Configuration Steps	• Enter the AC configuration mode. • Set the maximum number of APs connected to the AC to 512. • Use the **no** form of this command to restore the default setting.
AC	`Ruijie(config)#ac-controller` `Ruijie(config-ac)#wtp-limit 512` `Ruijie(config)#ac-controller` `Ruijie(config-ac)#no wtp-limit`
Verification	Run the **show ac-config** command to check the configured maximum number of APs that can be connected to the AC.
AC	`Ruijie#show ac-config` `…` `max_wtp :512` `…`

Common Errors

- N/A

1.4.17 Configuring the AP Compliance Check

Configuration Effect

- The AP compliance check is also called AP access control based on the bound MAC address, or bind-ap-mac function. If AP compliance check is enabled, only APs that have offline configurations bound with their MAC addresses are allowed to associate with the AC.

Notes

- N/A

Configuration Steps

- Optional. You can enable the AP compliance check to allow only APs with specified MAC address to go online, thus implementing strict control on access of APs.
- When the AP compliance check is enabled, all online APs are automatically bound with MAC addresses. Therefore, it is recommended that this function be disabled during network deployment, and enabled after all APs within the plan go online.
- When the **bind-ap-mac** function is enabled, MAC addresses automatically bound with all online APs are converted to the formal MAC address binding, which is not automatically deleted when APs go offline.
- On the AC device, you can run the **ap-mac** *X.Y.Z* command in AP configuration mode to configure the MAC address binding of an individual AP configuration.

Command	**bind-ap-mac** **no bind-ap-mac**
Parameter Description	N/A
Defaults	The AP compliance check is disabled by default.
Command Mode	AC configuration mode
Usage Guide	This command is used to enable the AP compliance check.

Command	**ap-mac** *ap-mac-address* **no ap-mac**
Parameter Description	*ap-mac-address*: indicates the MAC address that is bound.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	The **ap-mac***ap-mac-address* command is applicable to offline APs. You can use this command to specify the MAC address of an offline AP so that the AP configuration can be located directly based on the MAC address after the AP goes online.

Verification

- Run the **show running** command to check whether the **bind-ap-mac** function is enabled.
- Run the **show ap-config running** command to check the MAC address binding information of AP configurations.

Configuration Example

Enabling the bind-ap-mac Function on an AC

Configuration Steps	● After all authorized APs go online, enter the AC configuration mode and run the **bind-ap-mac** command to enable the bind-ap-mac function.
AC	`Ruijie(config)#ac-controller` `Ruijie(config-ac)#bind-ap-mac`
Verification	Run the **show running** command to check whether the bind-ap-mac function is enabled.
AC	`Ruijie#show running` `!` `ac-controller` `  bind-ap-mac` `!`

Common Errors

- N/A

1.4.18 Configuring AP Access Authentication

Configuration Effect

- AP access authentication can be implemented based on the serial number, password, or certificate.

Notes

- If you run the **ap-auth** { **serial** | **password** | **certificate** } **enable** command in AC configuration mode to enable the access authentication function, but do not run the **ap-auth** { **serial** *serial-string* |**password** *password* |**ac-cert** *ac-cert-name* |**ap-cert** *ap-cert-name* } command in AP configuration mode to configure related authentication parameters, AP access authentication will fail and the AP cannot go online.

Configuration Steps

- Optional.
- Run the **ap-auth serial-update** command to update the authentication serial numbers for all online APs.
- Run the **ap-auth enable** command in AC configuration mode to enable a specified type of AP access authentication.

- Run the **ap-auth** { **serial** *serial-string*|**password** *password* |**ac-cert** *ac-cert-name* |**ap-cert** *ap-cert-name* } command to configure the related AP access authentication parameters.

Command	**ap-auth serial-update**
Parameter Description	N/A
Defaults	This function is disabled by default.
Command Mode	AC configuration mode
Usage Guide	All online APs use the current AP serial numbers for authentication.

Command	**ap-auth** {**serial** |**password** |**certificate**} **enable**
Parameter Description	**serial**: indicates the authentication function based on the AP access serial number. **password**: indicates the authentication function based on the AP access password. **certificate**: indicates the authentication function based on the AP certificate.
Defaults	The authentication function is disabled by default.
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**ap-auth**{**serial** *serial-string*|**password** *password* |**ac-cert** *ac-cert-name*|**ap-cert** *ap-cert-name*}
Parameter Description	*serial-string*: indicates the AP access serial number. *password*: indicates the AP access password. *ac-cert-name*: indicates the AC certificate file name. *ap-cert-name*: indicates the AP certificate file name.
Defaults	This function is disabled by default.
Command Mode	AP configuration mode
Usage Guide	The AP access authentication configurations take effect only when the AP makes an access attempt. If the AP is already online, the configurations take effect next time when the AP goes online. The **ap-auth serial** command cannot be used in all-AP configuration mode because the serial number varies according to the AP. The certificate file issued by the **ap-auth ap-cert** command will be stored as **cert.crt** on the AP, and the file name cannot be changed.

Verification

- Run the **show ap-config running** command to check whether the configuration is successful.

Configuration Example

↘ Configuring the AP Access Authentication Function Based on the Serial Number

Configuration Steps	● After all authorized APs go online, update the authentication serial numbers for all online APs. ● Enable the AP access authentication function based on the serial number. ● Configure the authentication serial number of a specified AP.
AC	`Ruijie(config)#ac-controller` `Ruijie(config-ac)#ap-auth serial-update` `Ruijie(config)#ac-controller` `Ruijie(config-ac)#ap-auth serial enable` `Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#ap-auth serial G1GD10U000456`
Verification	Run the **show running** or **show ap-config running** command to check the AP access authentication configurations.
AC	`Ruijie(config)#show run` `!` `ac-controller` `  ap-auth serial enable` `!` `Ruijie(config)#show ap-config running Ruijie-AP1` `!` `ap-config Ruijie-AP1` `  ap-auth serial G1GD10U000456` `!`

↘ Updating the Access Authentication Certificate of an AP

Configuration Steps	● Update the access authentication certificate of an AP.
AC	`Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#ap-auth ap-cret ap1_cret.crt`
Verification	Run the **show ap-config running** command to check the name of the current AC. If the corresponding AP is online, the **ap1_cret.crt** file is updated to the AP instantly; otherwise, the file is updated to the AP after the AP goes online.
AC	`Ruijie(config)#show ap-config running Ruijie-AP1` `!`

	ap-config Ruijie-AP1 ap-auth ap-cret apl_cret.crt !

Common Errors

- N/A

1.4.19 Configuring the AP Priority

Configuration Effect

- By default, the AC allows the access of APs based on the sequence of AP association requests received by the AC. You can set the failover priorities of APs and enable the AC to support the failover priorities of APs so that the AC can allow the access of APs based on the AP priorities. The AP priority ranges from 1 to 4, where 1 is the lowest priority.

Notes

- N/A

Configuration Steps

- Optional. You can enable the AP priority function according to requirements and configure the priority of a specified AP.
- On the AC device, enter the AC configuration mode and run the **ap-priority** { **enable** | **disable** } command to enable or disable the AP priority function.
- On the AC device, enter the AP configuration mode and run the **priority** *priority-value* command to configure the priority of a specified AP.

Command	**ap-priority** { **enable**	**disable**}
Parameter Description	**enable**: enables the AP to support the failover priority. **disable**: disables the AP to support the failover priority.
Defaults	Disable
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**priority** *priority-value*
Parameter Description	priority-value: indicates the AP priority. The value ranges from 1 to 4, where 1 is the lowest priority.
Defaults	The default priority of an AP is 1. The priority can be set to a value from 1 to 4, where 1 is the lowest priority and 4 is the highest priority. You can run the **priority** command in AP configuration mode to configure the AP priority.

Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Run the **show running** or **show ap-config running** command to check the configurations.

Configuration Example

Setting the Priority of Ruijie-AP1 to 2 and Enabling the AP Priority Function

Configuration Steps	• Enter the AP configuration mode. • Configure the AP priority. • Enter the AC configuration mode. • Enable the AP priority function.
AC	`Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#priority 2` `Ruijie(config)#ac-controller` `Ruijie(config-ac)#ap-priority enable`
Verification	Run the **show running** command to check whether the **ap-priority enable** command is configured in AC configuration mode. Run the **show ap-config running** command to check the AP configurations.
AC	`Ruijie(config)#show running` `!` `ac-controller` `  ap-priority enable` `!` `Ruijie#show ap-config running` `!` `ap-config Ruijie-AP1` `  priority 2` `!`

Common Errors

- N/A

1.4.20 Configuring the AC Cluster Function

Configuration Effect

- AC cluster is also called AC redundancy. With this function, multiple ACs with different priorities are designated for an AP. When the connection between the AP and a high-priority AC is down, the AP is connected to a low-priority AC (standby AC). When the connection with the high-priority AC is recovered, the AP disconnects the CAPWAP tunnel with the low-priority AC, and sets up a CAPWAP tunnel with the high-priority AC again.
- On the one hand, the AC cluster function enhances reliability of the AC cluster. On the other hand, this function controls the home AC of APs in stable conditions based on the priority to facilitate AP management.

Notes

- For a specified AP, the same priority must be configured for this AP on each AC that belongs to the cluster. For example, on AC1, AC2 is configured as the primary AC for AP1, and AC1 is configured as the secondary AC for AP1. On AC2, AC1 is configured as the primary AC for AP1, and AC2 is configured as the secondary AC for AP1. That is, on both AC1 and AC2, the peer AC is configured as the high-priority AC for AP1. In this way, an endless loop is formed because the AP keeps switching between tunnels with two ACs.
- The redundancy AC configuration supports both the ap-config ap-name and ap-config all configuration modes. The redundancy AC configuration made in ap-config ap-name configuration mode takes precedence over that made in ap-config all configuration mode.
- Except the **primary-base** command, commands of other priorities do not support switchback to prevent network interruption caused by the switchback. The administrator can re-configure the priorities for a manual switchover, or configure the **switch-back** parameter for an automatic switchback.

Configuration Steps

- Optional. The redundancy AC configuration does not exist on an AP by default. You can configure redundancy ACs with different priorities for an AP based on the number of ACs deployed on the wireless network.
- Run the **primary-base** *ac-name* { *ip-address* | *ipv6-address* } command to configure the primary AC for a specified AP.
- Run the **secondary-base** *ac-name* { *ip-address* | *ipv6-address* } [**switch-back**] command to configure the secondary AC for a specified AP.
- Run the **tertiary-base***ac-name* { *ip-address* | *ipv6-address* } [**switch-back**] command to configure the tertiary AC for a specified AP.
- Run the **backup-controller-primary***ac-name* { *ip-address* | *ipv6-address* } [**switch-back**] command to configure the fourthAC for a specified AP.
- Run the **backup-controller-secondary***ac-name* { *ip-address* | *ipv6-address* } [**switch-back**] command to configure the fifthAC for a specified AP.
- Run the **backup-controller-tertiary***ac-name* { *ip-address* | *ipv6-address* } [**switch-back**] command to configure the sixthAC for a specified AP.

Command	**primary-base***ac-name* { *ip-address*	*ipv6-address* }

	no primary-base
Parameter Description	*ac-name*: indicates the name of the AC to be configured. *ip-address*: indicates the IP address of the primary AC. The format is A.B.C.D. *ipv6-address*: indicates the IPv6 address of the primary AC. The format is X;Y::Z.
Defaults	N/A
Command Mode	AP configuration mode (supporting the **ap-config all** configuration mode)
Usage Guide	N/A

Command	**secondary-base***ac-name* {*ip-address* | *ipv6-address* }[**switch-back**] **no secondary-base**
Parameter Description	*ac-name*: indicates the name of the AC to be configured. *ip-address*: indicates the IP address of the AC. The format is A.B.C.D. *ipv6-address*: indicates the IPv6 address of the AC. The format is X;Y::Z. **switch-back**: indicates the switchback function. Switchback is disabled by default.
Defaults	N/A
Command Mode	AP configuration mode (supporting the **ap-config all** configuration mode)
Usage Guide	N/A

Command	**tertiary-base***ac-name* {*ip-address* | *ipv6-address*}[**switch-back**] **no tertiary-base**
Parameter Description	*ac-name*: indicates the name of the AC to be configured. *ip-address*: indicates the IP address of the AC. The format is A.B.C.D. *ipv6-address*: indicates the IPv6 address of the AC. The format is X;Y::Z. **switch-back**: indicates the switchback function. Switchback is disabled by default.
Defaults	N/A
Command Mode	AP configuration mode (supporting the **ap-config all** configuration mode)
Usage Guide	N/A

Command	**backup-controller-primary***ac-name* {*ip-address* | *ipv6-address*}[**switch-back**] **no backup-controller-primary**
Parameter Description	*ac-name*: indicates the name of the AC to be configured. *ip-address*: indicates the IP address of the AC. The format is A.B.C.D. *ipv6-address*: indicates the IPv6 address of the AC. The format is X;Y::Z. **switch-back**: indicates the switchback function. Switchback is disabled by default.
Defaults	N/A

Command Mode	AP configuration mode (supporting the **ap-config all** configuration mode)
Usage Guide	N/A

Command	**backup-controller-secondary***ac-name* { *ip-address* | *ipv6-address*}[**switch-back**] **no backup-controller-secondary**
Parameter Description	*ac-name*: indicates the name of the AC to be configured. *ip-address*: indicates the IP address of the AC. The format is A.B.C.D. *ipv6-address*: indicates the IPv6 address of the AC. The format is X;Y::Z. **switch-back**: indicates the switchback function. Switchback is disabled by default.
Defaults	N/A
Command Mode	AP configuration mode (supporting the **ap-config all** configuration mode)
Usage Guide	N/A

Command	**backup-controller-tertiary***ac-name* { *ip-address* | *ipv6-address* }[**switch-back**] **no backup-controller-tertiary**
Parameter Description	*ac-name*: indicates the name of the AC to be configured. *ip-address*: indicates the IP address of the AC. The format is A.B.C.D. *ipv6-address*: indicates the IPv6 address of the AC. The format is X;Y::Z. **switch-back**: indicates the switchback function. Switchback is disabled by default.
Defaults	N/A
Command Mode	AP configuration mode (supporting the **ap-config all** configuration mode)
Usage Guide	N/A

Verification

- Run the **show ac-config** command to check the current AC name and determine whether the configuration is successful.

Configuration Example

Configuring Ruijie-AC1 as the Primary AC of Ruijie-AP1, and Ruijie-AC2 as the Secondary AC

Configuration Steps	• Enter the AP configuration mode. • Configure the primary AC and secondary AC of the AP.
Ruijie-AC1	`Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#primary-base Ruijie-AC1 5.5.5.5` `Ruijie(config-ap)#secondary-base Ruijie-AC2 6.6.6.6`

Ruijie-AC2	`Ruijie(config)#ap-config Ruijie-AP1` `Ruijie(config-ap)#primary-base Ruijie-AC1 5.5.5.5` `Ruijie(config-ap)#secondary-base Ruijie-AC2 6.6.6.6`
Verification	Run the **show ap-config running** command to check the AP configurations.
Ruijie-AC1	`Ruijie#show ap-config running` `!` `ap-config Ruijie-AP1` `  primary-base Ruijie-AC1 5.5.5.5` `secondary-base Ruijie-AC2 6.6.6.6` `!`
Ruijie-AC2	`Ruijie#show ap-config running` `!` `ap-config Ruijie-AP1` `  primary-base Ruijie-AC1 5.5.5.5` `secondary-base Ruijie-AC2 6.6.6.6` `!`

Common Errors

- N/A

1.4.21 Configuring the AC Hot Backup Function

Configuration Effect

- Set up the hot backup connection to ensure that the AP can set up two CAPWAP tunnels.

Notes

- N/A

Configuration Steps

- Optional. If an AP does not use the hot backup address of the AC to set up a tunnel, the AC address of the first tunnel must be specified. When IPv6must be used to set up the second channel, the IPv6 hot backup tunnel function must be enabled.
- Run the **peer-ip** command to configure the IP address for setting up a CAPWAP tunnel with the hot backup neighbor. This IP address will be pushed to the AP device, and the AP device will set up the second CAPWAP tunnel with the hot

backup neighbor based on the peer-ip address. If the AP does not use the default hot backup address of the AC to set up a tunnel, you need to configure the peer-ip address.

- Run the **peer-ipv6** command to configure the IPv6 address for setting up a CAPWAP tunnel with the hot backup neighbor. This IPv6 address will be pushed to the AP device, and the AP device will set up the second CAPWAP IPv6 tunnel with the hot backup neighbor based on the peer-ipv6 address. When an AP and an AC use the IPv6 address to set up a tunnel, you need to configure the peer-ipv6 address to set up the second CAPWAP IPv6 tunnel because currently IPv6 cannot be used for setting a hot backup connection between ACs.
- After the **peer-ipv6 enable** command is executed, the AP device sets up the second CAPWAP IPv6 tunnel with the hot backup neighbor. To set up a CAPWAP IPv6 tunnel between an AP and an AC, you must enable peer-ipv6so that the second CAPWAP IPv6 tunnel can be set up between the AP and the AC.
- Run the **ap-group** command to bind an AP group with the hot backup instance. After the AP group is bound with the hot backup instance, data of STAs associated with APs in the AP group can be synchronized from the active AC to the standby AC.

Command	**peer-ip***ipv4-address*
Parameter Description	*ipv4-address*: indicates the IP address used by the hot backup neighbor to set up a CAPWAP tunnel.
Defaults	Source address used by CAPWAP
Command Mode	Hot backup instance mode
Usage Guide	In the non-NAT environment, use the default setting, that is, the source address used by CAPWAP. In the NAT environment, configure the IPv6 address based on the environment where the AC and AP are located. When the AC is located inside the NAT, its address is a private network address, which is not accessible by the AP. Therefore, the AP must be notified of the configured public network address. ● If both the AP and the AC are within the NAT internal network, use the default setting. ● If the AP is in the NAT external network, use the IP address configured by the user as the peer AC address.

Command	**peer-ipv6***ipv6-address*
Parameter Description	*ipv6-address*: indicates the IPv6 address used by the hot backup neighbor to set up a CAPWAP tunnel.
Defaults	Source address used by CAPWAP
Command Mode	Hot backup instance mode
Usage Guide	In the non-NAT environment, use the default setting, that is, the source address used by CAPWAP. In the NAT environment, configure the IPv6 address based on the environment where the AC and AP are located. When the AC is located inside the NAT, its address is a private network address, which is not accessible by the AP. Therefore, the AP must be notified of the configured public network address. ● If both the AP and the AC are within the NAT internal network, use the default setting.

	● If the AP is in the NAT external network, use the IP address configured by the user as the peer AC address. You need to run the **peer-ipv6 enable** command to enable the function of using CAPWAP to set up the dual IPv6 hot backup tunnels.

Command	**peer-ipv6 enable**
Parameter Description	N/A
Defaults	Disable
Command Mode	Hot backup instance mode
Usage Guide	The peer-ipv6must be enabled when CAPWAP is used to set up an IPv6 tunnel between the AP and a hot backup AC so that the AP can use CAPWAP to set up an IPv6 tunnel with another hot backup AC.

Command	**ap-group** *ap-group*
Parameter Description	*ap-group*: indicates the name of an AP group.
Defaults	N/A
Command Mode	Hot backup instance mode
Usage Guide	After the AP group is bound with the hot backup instance, data of STAs associated with APs in the AP group can be synchronized from the active AC to the standby AC.

Verification

● Run the **show running** command to check the configurations.

Configuration Example

For details about the AC hot backup deployment solution, see "WLAN Hot Backup."

Enabling the AC to Use the Public Network Address as the AC Address

Configuration Steps	● Configure the hot backup address and enter the hot backup configuration mode. ● Configure the hot backup instance. ● In the hot backup instance configuration mode, configure the peer IP address.
AC	`Ruijie(config-hotbackup)# context 10` `Ruijie(config-hotbackup-ctx)# peer-ip 1.1.1.1`
Verification	Run the **show running** command to check the configurations.
AC	`Ruijie(config)#show running`

	wlan hot-backup 1.1.1.1 ! context 10 peer-ip 1.1.1.1

Common Errors

- N/A

1.4.22 Creating a WLAN

Configuration Effect

- You can create multiple WLANs on an AC and enter the configuration mode of a specified WLAN to configure related functions and properties of the WLAN according to the actual network requirements.
- The WLAN service template that is generated based on the following configurations can take effect only after the WLAN is deployed on a specified AP group. Wireless users can access related APs to access the WLAN.
- On the wireless network, you can divide the network into multiple WLAN subnets by creating WLANs. In addition, you can configure the functions and properties of a specified WLAN in WLAN configuration mode to provide different network services for wireless users.
- When creating a WLAN, you must associate the WLAN with an SSID, which is the name of a network service zone. One SSID can be mapped to one or multiple WLANs.

Notes

- N/A

Configuration Steps

- Optional. No WLAN is configured by default. You must create a WLAN before deploying the WLAN.
- Run the **wlan-config** command to create a WLAN, and use the **no** form of the command to delete the WLAN.

Command	**wlan-config***wlan-id* [*profile –string*][*ssid-string*] **no wlan-config***wlan-id*
Parameter Description	*wlan-id*: indicates the ID of a WLAN. The value ranges from 1 to 4094. *profile -string*: indicates the profile of the WLAN. This parameter is optional. The maximum length is 32 bytes. *ssid-string*: indicates the SSID. The maximum length is 32 bytes. When creating a WLAN, you must specify the SSID associated with the WLAN. Use the **no** form of the command to delete a specified WLAN.
Defaults	No WLAN is created by default.
Command Mode	Global configuration mode

Usage Guide	One SSID can be mapped to one or multiple WLANs, but one WLAN can be associated with only one SSID.

Verification

- Run the **show running** command to check the WLAN configurations.

Configuration Example

↘ Creating a WLAN

Configuration Steps	● Create WLAN 1. The SSID of WLAN 1 is ruijie-wireless.
AC	`Ruijie(config)#wlan-config 1 ruijie-wireless` `Ruijie(config-wlan)#`
Verification	Run the **show running** command to check the WLAN configurations.
AC	`Ruijie#show running` `!` `wlan-config 1 ruijie-wireless` `!`

Common Errors

- N/A

1.4.23 Deploying a WLAN

Configuration Effect

- The WLAN configuration takes effect only after the WLAN is deployed on a specified AP group. Wireless users can access the WLAN through the related APs. Run the **interface-mapping** command in AP group configuration mode to deploy the WLAN on a specified AP group. This command also configures the mapping between the WLAN and the VLANs or VLAN group of the wired network.

Notes

- Assume that the WLAN forwarding mode is local forwarding. In this case, if the vlan-id assigned to a STA in vlan-id or vlan-group mode configured by this **interface-mapping** command is the same as the vlan-id specified by the **ap-vlan** command, the real VLAN of the STA will be determined by the access switch of the AP, instead of the VLAN configured by the **interface-mapping** command or the VLAN assigned in vlan-group mode. In particular, the default vlan-id of the ap-vlan is 1. If the ap-vlan is not configured and the vlan-id configured in the **interface-mapping** command is 1, the VLAN of the STA in local forwarding mode is determined by the access switch.

Configuration Steps

- Optional. You can run the **interface-mapping** command in AP group configuration mode to configure a WLAN and deploy the WLAN on all APs in the AP group.
- On the AC device, enter the AP configuration mode and run the **interface-mapping** command for configuration.

Command	**interface-mapping***wlan-id*{*vlan-id* I **group***vlan-group-id*}[**radio**{*radio-id*	[*802.11b*	*802.11a*]}] [**ap-wlan-id***ap-wlan-id*]
Parameter Description	*wlan-id*: indicates the ID of the specified WLAN. This WLAN must have been created. The WLAN ID ranges from 1 to 4094. *vlan-id*: indicates the ID of the specified VLAN. The VLAN ID ranges from 1 to 4094. vlan-group-id: indicates the ID of the specified VLAN group. The VLAN group ID ranges from 1 to 128. r*adio-id*: indicates the ID of the radio of a specified AP. If radio-id is not specified, the mapping is applied to all radios of all APs in the AP group. The radio ID ranges from 1 to 96. *802.11b*: indicates that the mapping is applied to all 2.4 GHz radios of all APs in the AP group. *802.11a*: indicates that the mapping is applied to all 5.8 GHz radios of all APs in the AP group. *ap-wlan-id*: specifies the wlan-id that is used on the AP through interface-mapping. The value ranges from 1 to 64.
Defaults	By default, the WLAN is not deployed on any AP.
Command Mode	AP group configuration mode
Usage Guide	If the **ap-wlan-id** parameter is not specified, the mapping automatically selects and uses an idle ap-wlan-id.

Verification

- Run the **show running** command to check the AP group configurations.

Configuration Example

Configuring a WLAN and Deploying the WLAN on a Specified AP Group

Configuration Steps	Ruijie-AP1 belongs to the AP group APG-1. Create a WLAN, and deploy the WLAN on Ruijie-AP1. - Create WLAN 1. The SSID of WLAN 1 is ruijie-wireless. - Create VLAN 1. - Configure the WLAN-VLAN mapping in AP group configuration mode.
AC	`Ruijie(config)#wlan-config 1 ruijie-wireless` `Ruijie(config-wlan)#exit` `Ruijie(config)#vlan 1` `Ruijie(config-vlan)#exit` `Ruijie(config)#ap-group APG-1`

	`Ruijie(config-ap-group)#interface-mapping 1 1`
Verification	Run the **show running** command to check the AP group configurations.
	`Ruijie#show running` `!` `wlan-config 1 ruijie-wireless` `!` `!` `ap-group APG-1` `  interface-mapping 1 1` `!`

Common Errors

- N/A

1.4.24 Enabling or Disabling WLAN SSID Broadcasting

Configuration Effect

- On the WLAN, the AP periodically broadcasts the SSID information to notify other entities of the existence of the wireless network. Wireless users use the wireless network interface cards (NICs) to search SSIDs and detect the wireless network. The SSID broadcasting function can be enabled to prevent the wireless network from being searched and connected by unauthorized users based on the SSID.

Notes

- N/A

Configuration Steps

- Optional. WLAN SSID broadcasting is enabled by default. If the WLAN SSID should be hidden to prevent the wireless network from being searched and connected by unauthorized users based on the SSID, you can disable the WLAN SSID broadcasting function.
- On the AC device, enter the WLAN configuration mode and run the **enable-broad-ssid** command for configuration.

Command	**enable-broad-ssid** **no enable-broad-ssid**
Parameter Description	N/A
Defaults	WLAN SSID broadcasting is enabled by default.
Command Mode	WLAN configuration mode

Usage Guide	WLAN SSID broadcasting is enabled by default. You can use the **no** form of the command to disable this function. If the SSID broadcasting configuration of the WLAN changes, users associated with the WLAN will go offline.

Verification

- Run the **show running** command to check the WLAN configurations.

Configuration Example

Disabling SSID Broadcasting of WLAN 1

Configuration Steps	• Enter the WLAN configuration mode. • Disable SSID broadcasting.
AC	`Ruijie(config)#wlan-config 1` `Ruijie(config-wlan)#no enable-broad-ssid`
Verification	Run the **show running** command to check the WLAN configurations.
AC	`Ruijie#show running` `!` `wlan-config 1 ruijie-wireless` `  no enable-broad-ssid` `!`

Common Errors

- N/A

1.4.25 Configuring the NAS ID of a WLAN User

Configuration Effect

- On the WLAN, the NAS IDs of WLAN users identify different hot spot areas. By default, the NAS ID of a WLAN user is a null string.

Notes

- N/A

Configuration Steps

- Optional.
- On the AC device, enter the WLAN configuration mode and run the **nas-id** command to configure the NAS ID.

Command	**nas-id** *wlan-nas-id*

	no nas-id
Parameter Description	N/A
Defaults	Null string
Command Mode	WLAN configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to check the WLAN configurations.

Configuration Example

Configuring the NAS ID of a WLAN User

Configuration Steps	• Enter the WLAN configuration mode. • Configure the NAS ID of a WLAN user.
AC	`Ruijie(config)#wlan-config 1` `Ruijie(config-wlan)#nas-id0000059159100460`
Verification	Run the **show running** command to check the WLAN configurations.
AC	`Ruijie#show running` `!` `wlan-config 1 ruijie-wireless` `nas-id0000059159100460` `!`

Common Errors

- N/A

1.4.26 Configuring the Fit or Fat AP Mode

Configuration Effect

- On the AC device, run the **switch2fat** command in AC configuration mode to switch the mode of an online AP to the fat AP mode.
- On the AC device, run the **ap-mode** command in global configuration mode to switch between the fit AP mode and the fat AP mode.

Notes

- If the **switch2fat** command is executed on the AC in AP configuration mode to switch the mode of an online AP to the fat AP mode, the AP will be disconnected from the AC. After that, you cannot configure the AP on the AC.

Configuration Steps

- Optional. For an AC, an online AP definitely works in fit AP mode. You can run the **switch2fat** command if you need to switch the mode of the AP to the fat AP mode.
- On the AC device, run the **switch2fat** command in AC configuration mode to switch the mode of an online AP to the fat AP mode.
- On the AC device, run the **ap-mode** command in global configuration mode to switch between the fit AP mode and the fat AP mode.

Command	**switch2fat** *ap-name*
Parameter Description	*ap-name*: indicates the name of a specified AP.
Defaults	By default, all fit APs are controlled by the associated AC. A fit AP can be switched to a fat AP to implement self-control.
Command Mode	AC configuration mode
Usage Guide	This command takes effect only on an online AP.

Command	**ap-mode**{ **fit** | **fat**[**dhcp**]}
Parameter Description	**fit**: indicates that the AP mode is switched to the fit AP mode. **fat:** indicates that the AP mode is switched to the fat AP mode. **dhcp**: If the **ap-mode fat** command contains this parameter, the AP obtains the IP address through DHCP by default after the AP mode is switched to the fat AP mode; otherwise, the AP uses the static IP address by default after the AP mode is switched to the fat AP mode.
Defaults	N/A
Command Mode	AP global configuration mode
Usage Guide	After the AP mode is switched between the fit and fat AP modes, the AP must be restarted to ensure the configuration consistency. For WALL-APs supplied by Ruijie Networks, when the fat AP mode is used, the default IP address of the rear wired network interface (connected to the PoE switching device) is 192.168.110.1/255.255.255.0, and the default IP address of the front wired network interface (Ethernet interface) is 192.168.111.1/255.255.255.0. If **ap-mode fat dhcp** is configured, when the AP mode is switched to the fat AP mode, the IP address is obtained through DHCP by default. After the AP is restarted, if related configuration is not available, the IP address is still obtained through DHCP by default. In addition, the following two issues should

	also be noted: 1.If **ap-mode fat dhcp** is configured for the WALL-AP, only the IP address of the rear wired network interface is obtained through DHCP, and the front wired network interface uses the static IP address by default. 2.In fat AP mode, the **ap-mode fat dhcp** and **ap-mode fat** commands cannot be mutually switched, and must be switched to the fit AP mode first. In fit mode, the default password for the user EXEC mode is **ruijie** and that for the privileged EXEC mode is **apdebug**. In fat/fat dhcp/macc mode, the default password for user EXEC mode is **admin** and that for the privileged EXEC mode is empty.

Verification

- On the AP, run the **show ap-mode** command to check the current mode of the AP.

Configuration Example

Switching the Mode of the Online AP Ruijie-AP1 to the Fat AP Mode on the AC

Configuration Steps	• Enter the AC configuration mode. • Run the **switch2fat** command.
AC	`Ruijie(config)#ac-controller` `Ruijie(config-ac)#switch2fat Ruijie-AP1`
Verification	On the AP, run the **show ap-mode** command to check the current mode of the AP.
AP	`Ruijie#show ap-mode` `current mode: fat`

Common Errors

- N/A

1.4.27 Configuring the WLAN SSID

Configuration Effect

- Configure a new SSID for the WLAN. If this WLAN has been deployed, all users associated with this WLAN will go offline.
- Configure the coded character set for the SSID. If the WLAN is deployed, all users of this WLAN will go offline.

Notes

- N/A

Configuration Steps

- Optional.

- On the AC device, enter the WLAN configuration mode and run the **ssid** command to configure the new SSID.

Command	**ssid** *ssid-string*
Parameter Description	N/A
Defaults	N/A
Command Mode	WLAN configuration mode
Usage Guide	N/A

- On the AC device, enter the WLAN configuration mode and run the **ssid-code** command to configure the coded character set for the SSID.

Command	**ssid-code** { **gbk** | **utf-8** }
Parameter Description	**gbk**: Configures gbk. **utf-8**: Configures utf-8.
Defaults	N/A
Command Mode	WLAN configuration mode
Usage Guide	If the WLAN is deployed, all users of this WLAN will go offline.

Verification

- Run the **show running** command to check the WLAN configurations.

Configuration Example

↘ Configuring a New SSID "ruijie" for WLAN 1

Configuration Steps	• Enter the WLAN configuration mode. • Configure a new SSID "ruijie".
AC	`Ruijie(config)#wlan-config 1` `Ruijie(config-wlan)#ssid ruijie`
Verification	Run the **show running** command to check the WLAN configurations.
AC	`Ruijie#show running` `!` `wlan-config 1 ruijie` `!`

Common Errors

- N/A

1.4.28 Configuring the AP Backup Function

Configuration Effect

- If the active AP in an AP backup group is faulty and disconnected, other standby APs in the group receive the WLAN configuration of the active AP and transmit radio signals of the active AP.

Notes

- In an AP backup group, if the active AP is not selected, the AP backup function does not take effect.

Configuration Steps

Configuring an AP Backup Group

- Optional. Create an AP backup group when the wireless network of an AP needs to be backed up.
- In AC configuration mode, run the **ap-backup group** command to create an AP backup group.

Command	**ap-backup group** *backup-group*
Parameter Description	*backup-group*: indicates the name of the AP backup group.
Defaults	By default, if only the AP backup group named "default" exists on the AC, the backup function of this group does not take effect.
Command Mode	AC configuration mode
Usage Guide	N/A

Adding APs to an AP Backup Group

- Optional. When the wireless network of an AP must be backed up by other APs, add the standby APs and the AP to be backed up to the AP backup group, and select the AP to be backed up as the active AP.
- In AP configuration mode, run the **ap-backup-group** command to add the AP to the AP backup group. When adding an AP to an AP backup group, you can specify whether the AP is the active AP.

Command	**ap-backup-group** *backup-group***[master]**
Parameter Description	*backup-group*: indicates the name of the AP backup group.
Defaults	By default, the AP is not added to the default group, and the backup function of the backup group does not take effect.
Command Mode	AP configuration mode
Usage Guide	This command does not support the ap-config all mode. The keyword **master** is optional. If the command contains this keyword, the AP is designated as the active AP of the group; otherwise, the AP is the standby AP. An AP backup group can have multiple standby APs but only one active AP.

	When the AP backup group starts to work, that is, the standby APs have inherited WLAN signals from the active AP, note that the following four operations change the WLAN configurations of the standby APs that should take effect, and the inherited WLAN signals will take effect again: 1. Modify the WLAN configurations of the AP group to which the standby APs belong. 2. Modify the WLAN configurations of the AP group to which the active AP belongs. 3. Change the AP group of the standby APs. 4. Change the AP group of the active AP. If online users already exist, these users will go offline.

Verification

- Run the **show ap-config running** and **show ac-config ap-backup-group** commands to check the configurations.

Configuration Example

Creating an AP Backup Group Named "APBACK-APG-1"

Configuration Steps	● In AC configuration mode, run the **ap-backup group** command to create an AP backup group.
AC	`Ruijie(ac-config)#ap-backup group APBACK-APG-1`
Verification	● Run the **show ac-config ap-backup-group** command to check the configurations.
AC	`Ruijie#show ac-config ap-backup-group` `Cnt Group-Name Master-AP cntStandby-AP cnt Master-AP-Name Working` `------ ---------- ---------- ---------- ---------- -------` `1 APBACK-APG-1 1 2 AP4210-1 false`

Adding ap4210-1 to the AP Backup Group Named "APBACK-APG-1", and Configuring this AP as the Active AP of the Group

Configuration Steps	● In AP configuration mode, run the **backup-group** command to add the AP to the AP backup group.
AC	`Ruijie(ap-config)#ap-backup-group APBACK-APG-1 master`
Verification	● Run the **show ac-config ap-backup-group** command to check the configurations.
AC	`Ruijie#show ac-config ap-backup-groupAPBACK-APG-1` `Cnt Ap-Name Ap-Mac Online Is-Master Inherit-Wlan Cnt`

	------- ---------------------- ------------------- ------- ------------ -- ---------- 1 AP4210-1 8832.0000.1111 true Yes 0

Common Errors

- N/A

1.4.29 Configuring AC Virtualization Function

Configuration Effect

- After an administrator logs in to the web management page, the administrator can only check and configure authorized WLANs, AP groups, and APs (STAs).

Notes

- N/A

Configuration Steps

Configuring AC Virtualization Function

- Optional. When multiple administrators are required in a wireless environment to manage different wireless networks and APs, enable the AC virtualization function.
- Run the **permit enable** command in AC configuration mode to enable the AC virtualization function.
- Run the **master-group** command in global configuration mode to create a role and enter the role configuration mode.
- Run the **master-group** command in AP configuration mode to assign an AP to a specific role.
- Run the **master-group** command in AP group configuration mode to assign an AP group to a specific role.
- Run the **master-group** command in WLAN configuration mode to assign a WLAN to a specific role.
- Run the **webmaster** command in role configuration mode to add/delete an administrator.

Command	**permit enable**
Parameter Description	N/A
Defaults	The AC virtualization function is disabled by default.
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**master-group** *master-group-name*
Parameter Description	*master-group-name*: Indicates the role name.

Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	When the **no** form of this command is used to delete a role, APs, AP groups, and WLANs assigned to the role are restored to the unassigned state and the administrator of this role is restored to the default role-free state.

Command	**master-group** *master-group-name*
Parameter Description	*master-group-name*: Indicates the role name.
Defaults	N/A
Command Mode	AP/AP group/WLAN configuration mode
Usage Guide	After a role is deleted, APs, AP groups, and WLANs assigned to the role are restored to the default unassigned state.

Command	**webmaster** *webmaster-name*
Parameter Description	*webmaster-name*: Indicates the administrator name.
Defaults	N/A
Command Mode	Role configuration mode
Usage Guide	When a role is deleted, the administrator of the role is restored to the default role-free state.

Verification

- Run the **show running-config** and **show ap-config running** commands to display configurations.

Configuration Example

↘ Enabling AC virtualization function

Configuration Steps	● Run the **permit enable** command in AC configuration mode to enable the AC virtualization function.
AC	`Ruijie(ac-config)# permit enable`
Verification	● Run the **show running-config** command to display configurations.
AC	`Ruijie# show running-config | begin ac-controller` `ac-controller` ` permit enable`

	ac-name Ruijie country CN

Creating Role test-group and Adding Administrator test-admin-1 for the Role

Configuration Steps	● Run the **master-group** command in global configuration mode to create the role (test-group) and enter the role configuration mode. ● Run the **webmaster** command in role configuration mode to add the administrator (test-admin-1).
AC	Ruijie(config)# master-group test-group Ruijie(config-master-group)# webmaster test-admin-1
Verification	● Run the **show running-config** command to display configurations.
AC	Ruijie# show running-config | begin master-group master-group test-group webmaster test-admin-1

Assigning AP (ap-1), AP Group (apg-1), and WLAN (1) to Role test-group

Configuration Steps	● Run the **master-group** command in AP configuration mode to assign the AP (ap-1) to the role (test-group). ● Run the **master-group** command in AP group configuration mode to assign the AP group (apg-1) to the role (test-group). ● Run the **master-group** command in WLAN configuration mode to assign the WLAN (1) to the role (test-group).
AC	Ruijie(config)# ap-config ap-1 Ruijie(config-ap)# master-group test-group Ruijie(config-ap)# exit Ruijie(config)# ap-group apg-1 Ruijie(config-group)# master-group test-group Ruijie(config-group)# exit Ruijie(config)# wlan-config 1 Ruijie(config-wlan)# master-group test-group
Verification	● Run the **show running-config** and **show ap-config running** commands to display configurations.
AC	Ruijie# show running-config | begin wlan-config 1 wlan-config 1 Ruijie master-group test-group ! Ruijie# show running-config | begin ap-group apg-1

	ap-group apg-1 master-group test-group ! Ruijie# show ap-config running | begin ap-config ap-1 ap-config ap-1 master-group test-group !

Common Errors

- N/A

1.4.30 Configuring the AP Virtualization Function

Configuration Effect

- Multiple ACs can assign their own WLANs to the same AP, and the STAs connect to the virtual APs served by corresponding ACs.

Notes

- ACs cannot send the same signal.

Configuration Steps

Configuring an AP Virtualization Template

- Optional. Configure an AP virtualization template when multiple ACs need to manage the same AP.
- In global configuration mode, run the **virtual-ap** command to create an AP virtualization template.

Command	**virtual-ap** *sub-ap-name*
Parameter Description	*sub-ap-name*: Indicates the name of an AP virtualization template.
Defaults	No AP virtualization template is created by default.
Command Mode	AC global configuration mode
Usage Guide	N/A

Configuring the IP Address of the AC to Which a Virtual AP is to Connect

- Optional. If the IP address of the AC to which a virtual AP is to connect is not configured, the virtual AP created on the AP using the AP virtualization template cannot connect to the AC.

Command	**ac-ip** *ip*
Parameter Description	*ip*: Indicates the IPv4 address of the AC to which a virtual AP is to connect.
Defaults	The virtual APs created on the AP using the AP virtualization template cannot connect to ACs by default.

Command Mode	AP virtualization template configuration mode
Usage Guide	This command is configured in the AP virtualization template. The AP disconnects all tunnels and reconnects them each time the configurations are changed. The configured IP address cannot be the IP address of the active AC, and can only be the IP address of the AC to be connected and the address of the loopback 0 interface or the CAPWAP control IP address if any.

Configuring the Number of WLANs Supported by a Virtual AP

- Optional. If the number of WLANs supported by a virtual AP is not configured, it is calculated as follows:
  (Total number of WLANs supported by the AP – Number of WLANs configured for virtual APs)/Number of virtual APs with the number of supported WLANs not configured

Command	**wlan-capacity** *wlan-cap*
Parameter Description	*wlan-cap*: Indicates the number of WLANs supported by a virtual AP.
Defaults	The number of WLANs supported by a virtual AP is not configured by default.
Command Mode	AP virtualization template configuration mode
Usage Guide	This command is configured in the AP virtualization template. In default configuration mode, if the remaining number of WLANs is 0, the virtual AP cannot send wireless signals. The AP disconnects all tunnels and reconnects them each time the configurations are changed.

Configuring the Number of STAs Supported by a Virtual AP

- Optional. If the number of STAs supported by a virtual AP is not configured, it is calculated as follows:
  (Total number of STAs supported by the AP – Number of STAs configured for virtual APs)/Number of virtual APs with the number of supported STAs not configured

Command	**sta-capacity** *sta-cap*
Parameter Description	*sta-cap*: Indicates the number of STAs supported by a virtual AP.
Defaults	The number of STAs supported by a virtual AP is not configured by default.
Command Mode	AP virtualization template configuration mode
Usage Guide	This command is configured in the AP virtualization template. In default configuration mode, if the remaining number of STAs is 0, the virtual AP cannot send wireless signals.

	The AP disconnects all tunnels and reconnects them each time the configurations are changed.

Configuring the Uplink Interface Used by a Virtual AP

- Optional. If the uplink interface used by a virtual AP is not configured, the virtual AP uses the uplink interface used by the active AC.

Command	**link-interface** { *other* | *num}*
Parameter Description	*other*: Indicates that a virtual AP uses an uplink interface different from that used by the active AC. This parameter is specified when there are two uplink interfaces and virtual AP and active AC use them for connection. *num*: Indicates the number of uplink interface used by a virtual AP.
Defaults	A virtual AP uses the uplink interface used by the active AC by default.
Command Mode	AP virtualization template configuration mode
Usage Guide	This command is configured in the AP virtualization template. In default configuration mode, a virtual AP uses the uplink interface used by the active AC to establish a CAPWAP connection. The **other** parameter is configured only when there are two uplink interfaces and the virtual AP and active AC use them for connection. Otherwise, the virtual AP cannot establish a CAPWAP connection to the corresponding AC. If the configured uplink interface number does not exist, the virtual AP cannot establish a connection to the corresponding AC. The AP disconnects all tunnels and reconnects them each time the configurations are changed. If multiple uplink interfaces exist and the **other** or **num** parameter is configured after the aggregation function is configured, the virtual AP cannot establish a CAPWAP connection to the corresponding AC.

Configuring Virtual APs for an AP

- Optional. If virtual APs are not configured for an AP, the AP does not create virtual APs.

Command	**virtual-ap** *sub-ap-name* {**id** *num}*
Parameter Description	*sub-ap-name*: Indicates the name of an AP virtualization template. *num*: (Optional) Indicates the number of a virtual AP on the AP, which starts from 1 by default.
Defaults	An AP does not create virtual APs by default.
Command Mode	AP, AP group, and all-AP configuration modes
Usage Guide	This command is configured in AP, AP group, and all-AP configuration modes.

	In a configuration mode, multiple virtual APs can be configured but the virtual APs cannot have the same AC IP address except the default one. The AP disconnects all tunnels and reconnects them each time the configurations are changed. Configurations of the **virtual-ap** command are delivered based on the following priority sequence: Configurations in AP configuration mode > Configurations in AP group configuration mode > Configurations in all-AP configuration mode.

Configuring the Duration for a Virtual AP to Continue Service Provision After the Connection Between the AP and Active AC is Down

- Optional. If the duration for a virtual AP to continue service provision after interruption of the connection between the AP and active AC is not configured, the virtual AP continues to provide services for one day.

Command	**ap-idle-timeout** *num*
Parameter Description	*num*: Indicates the duration (in the unit of day) for a virtual AP to continue service provision after he connection between the AP and active AC is down. The value ranges from **0** to **14**.
Defaults	A virtual AP continues to provide services for one day by default after the connection between the AP and active AC is down.
Command Mode	AP, AP group, and all-AP configuration modes
Usage Guide	This command is configured in AP, AP group, and all-AP configuration modes. If the **num** parameter is set to **0** to prevent tunnel instability, the tunnel between the virtual AP and corresponding AC is not torn down immediately but retained for two minutes. After an AP disconnects from the active AC and the time specified in **ap-idle-timeout** has not expired, a virtual AP no longer connects to an AC if the tunnel between the virtual AP and corresponding AC is disconnected, and connects to the AC again only when the connection between the AP and active AC is re-established.

Verification

- Run the **show running** command to display configurations.

Configuration Example

Creating an AP Virtualization Template Named VAP-1

Configuration Steps	Run the **virtual-ap** command in AC global configuration mode to create the AP virtualization template named VAP-1.
AC	`Ruijie(config)#virtual-ap VAP-1` `Ruijie(config-virtual-ap)# wlan-capacity 6` `Ruijie(config-virtual-ap)# sta-capacity 6` `Ruijie(config-virtual-ap)# ac-ip 1.1.1.1`

	Ruijie(config-virtual-ap)# link-interface 2
Verification	● Run the **show running-config** command to display configurations.
AC	Ruijie#show running-config Building configuration... Current configuration: 6069 bytes version AC_RGOS 11.1(5)B00, Release(04150906) ! virtual-ap VAP-1 ac-ip 1.1.1.1 wlan-capacity 6 sta-capacity 16 link-interface 2 !

↘ Applying AP Virtualization Template VAP-1 to AP1

Configuration Steps	● Run the **virtual-ap** command in AP configuration mode, configuration mode of the AP group in which AP1 resides, or all-AP configuration mode.
AC	Ruijie(config)#ap-config AP1 You are going to config AP(AP1), which is not online now. Ruijie(config-ap)#virtual-ap VAP-1 Ruijie(config-ap)#
Verification	● Run the **show ap-config running** command to display configurations.
AC	Ruijie(config-ap)#show ap-c running ! ap-config AP1 virtual-ap VAP-1 id 1 !

Common Errors

- N/A

1.4.31 Configuring the Default SSID

Configuration Effect

- When a fit AP starts or the CAPWAP tunnel of the AP is disconnected, the AP releases a 2.4G unencrypted SSID signal. When the CAPWAP tunnel is set up, the SSID is disabled.

Notes

- If RIPT is configured and the tunnel is torn down, signals are not sent.
- When the AP is restarted, the configurations will be saved.

Configuration Steps

- Optional.
- On the AC, run the **offline-ssid** command in AP, AP group, or all-AP configuration mode to specify the SSID signal of the AP.

Command	**offline-ssid** *ssid* **[hide]** **no offline-ssid**
Parameter Description	*ssid*: Indicates the SSID signal broadcasted when the AP is started or the tunnel is torn down. **hide**: Indicates that no SSID signal is broadcasted.
Defaults	No SSID is configured by default.
Command Mode	AP configuration mode AP group configuration mode All-AP configuration mode
Usage Guide	N/A

Verification

- Run the **show running** or **show ap-config running** command to display configurations.

Configuration Example

↘ Configuring the Default SSID of AP1 to my-def-ssid

- Configure the default SSID of the default AP group to my-group-ssid.

Configuration Steps	
AC	`Ruijie(config)#ap-config AP1` `Ruijie(config-ap)#offline-ssid my-def-ssid` `Ruijie(config-ap)#exit` `Ruijie(config)#ap-group default` `Ruijie(config-ap-group)#offline-ssid my-group-ssid`
Verification	Run the **show running** command to check whether the command is configured in all-AP and AP group configuration modes. Run the **show ap-config running** command to check the current configurations of the AP.
AC	`Ruijie(config)#show running` `!` ap-group default

	offline-ssid my-group-ssid ! Ruijie#show ap-config running ! ap-config AP1 offline-ssid my-def-ssid !

Common Errors

1.5 Monitoring

Displaying

Description	Command
Displays the basic configurations of the current AC	**show ac-config**
Displays the AP backup group information	**show ac-config ap-backup-group**
Displays the BSSID list of all APs	**show ap-config bssid**
Displays the AP status information	**show ap-config cb**
Displays the WLAN information inherited by the AP	**show ap-config inherit-wlan**
Displays the AP product list	**show ap-config product**
Displays the current status of all APs	**show ap-config summary**
Displays authentication-related information of all APs	**show ap-config summary ap-auth**
Displays APs that try to associate with the AC but are rejected by the AC	**show ap-config summary deny-ap**
Displays the information about all hot backup APs associated with the AC	**show ap-config summary hot-backup**
Displays the APs in a specified AP group	**show ap-group aps**
Displays the APs in all AP groups	**show ap-group aps summary**
Displays the basic information about a specified AP	**show ap-group cb**
To display the WLAN-VLAN mapping of a specified AP group	**show ap-group intf-wlan-map**
Displays all APs	**show ap-group summary**
Displays the fit or fat mode of the AP	**show ap-mode**
Displays the basic information about a specified WLAN	**show wlan-config cb**

Description	Command
Displays the WLAN configuration list on the AC	**show wlan-config summary**

2 Configuring STA Management

2.1 Overview

STA Management (STAMG) implements station (STA) management, including STA access control management and STA event notification. Event notification is mainly used to serve other function modules. Applications of the STAMG functions are as follows:

- The dynamic blacklist is used on a security-sensitive network to prevent user attacks.
- The STA limit is used when the number of STAs exceeds the AP capacity.
- Load balancing is used when STAs need to be evenly distributed to multiple APs.
- Association control is used in the E-bag scenario.

Protocols and Standards

- N/A

2.2 Applications

Application	Description
Fit AP Networking	In fit AP network mode, at least one AC and one AP are required.
Large Conference Room	In fit AP network mode, at least one AC and two APs are required.
E-Bag	In fit AP network mode, at least one AC and two APs are required.

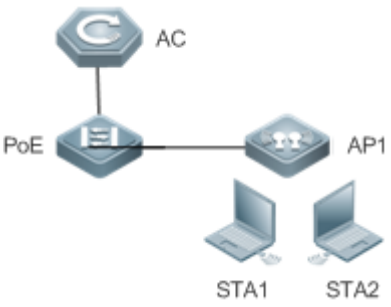
2.2.1 Fit AP Networking

Scenario

One AC is deployed on the wireless network, and dynamic blacklist and STA limit functions are enabled on the AC.

As shown in Figure 2-1, dynamic blacklist and STA limit are enabled on the AC.

Figure 2-1



Remarks	AC is the wireless access controller. PoE is the switch that functions as the gateway of APs. AP is the wireless access device. STA1 and STA2 are user devices.

Deployment

- Enable dynamic blacklist and STA limit on the AC.

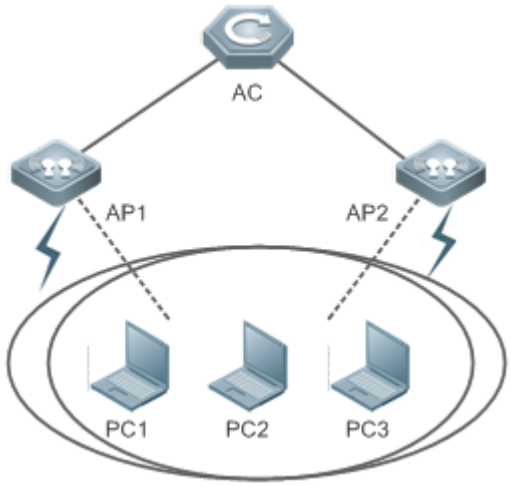
2.2.2 Large Conference Room

Scenario

In a large conference room, the number of STAs is generally large, and STAs must be evenly distributed to multiple APs; otherwise, too many STAs are connected to some specific APs, resulting in a low network speed and a poor user experience.

As shown in Figure 2-2, two APs (AP1 and AP2) are deployed in the conference room so that STAs can be evenly distributed to the two APs.

Figure 2-2



Remarks	AC is the wireless access controller. AP1 and AP2 are wireless access devices. PC1, PC2, and PC3 are user devices.

Deployment

- Enable load balancing on the AC, and add AP1 and AP2 to the load balancing group.

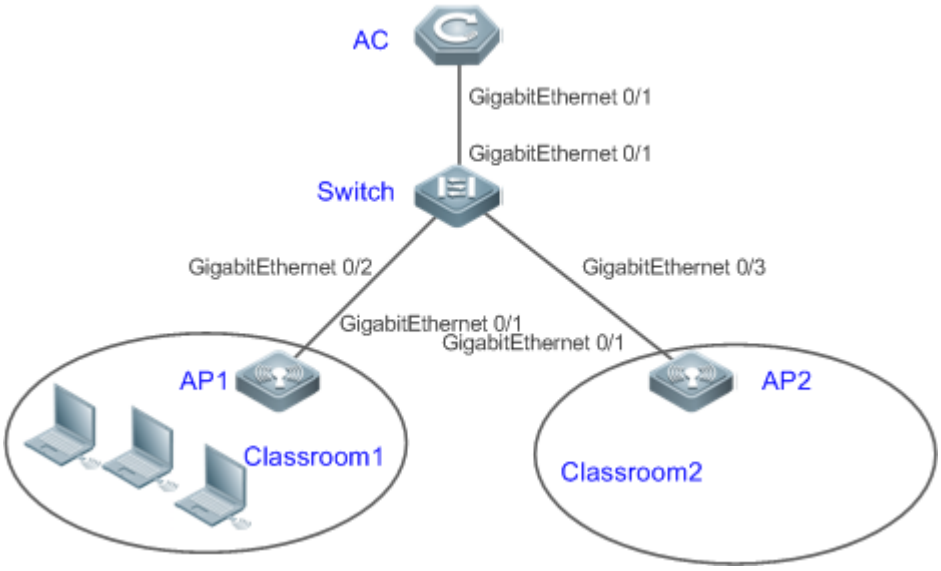
2.2.3 E-Bag

Scenario

One AC is deployed on the wireless network, and multiple APs are deployed in different classrooms. When the teacher's STA is associated with an AP, the students' STAs must also be associated with the same AP. This ensures the network transmission speed.

As shown in Figure 2-3, AP1 is deployed in Classroom1 and AP2 is deployed in Classroom2. When the teacher's STA is associated with AP1, the students' STAs must also be associated with AP1, instead of AP2. In this way, traffic destined for Classroom1 is only sent to AP1 without affecting users on AP2.

Figure 2-3



Remarks	AC is the wireless access controller. Switch functions as the gateway of APs. AP1 and AP2 are wireless access devices.

In the E-bag scenario, if the teacher uses the wired network connection, one of STAs used by students must be configured as the primary STA to implement association control. Who uses this primary STA is determined by users themselves. For example, the primary STA can be used by the class monitor or the teacher so that secondary STAs can be associated correctly. After correct association of the secondary STAs, the teacher can put this primary STA aside, and use the wired network connection during the class.

Deployment

- Enable association control on the AC, and add APs to a specified association control zone.

2.3 Features

Overview

Feature	Description
Dynamic Blacklist	Detects association of unauthorized users.
STALimit	Limits the number of STAs.
Load Balancing	Distributes STAs evenly to multiple APs.
Inter-Radio Load Balancing	Distributes STAs evenly to multiple radios of the same AP.
Association Control	Associates secondary STAs with APs in the same control zone if the primary STA is associated with these APs.
STA Management	Disassociates STAs without traffic forcibly to recycle resources.
STA Informational Syslog Suppression	Suppresses the informational syslog output rate of STAs.
Intelligent SSID Hiding	Hides the SSID when the number of STAs on an AP or radio reaches the upper limit.

2.3.1 Dynamic Blacklist

The AC can use the dynamic blacklist to punish malicious or unauthorized STAs so that these STAs cannot be associated within a period of time. In addition, the dynamic blacklist can be used to disassociate these STAs.

Working Principle

The number of STA association failures (including failures caused by incorrect user names or passwords) is counted in a period of time. When the number of association failures of an STA exceeds a certain threshold, the STA is added to the blacklist. STAs in the blacklist cannot be associated within a period of time.

2.3.2 STA Limit

STA limit aims to limit the number of STAs that can be associated with an AP based on the load capacity. This prevents the risk of insufficient resources caused by overload of APs.

Working Principle

When STAs are associated, the AP checks whether the number of associated STAs exceeds the threshold. If yes, STAs cannot be associated.

2.3.3 Load Balancing

Load balancing can balance the load among APs managed by an AC. The load here can be traffic or the number of associated STAs. The purpose is to prevent the problem that some APs are overloaded and some APs are in the idle state.

Working Principle

When an STA tries to be associated, if the load on the AP associated by the STA exceeds the preset threshold, the system checks whether the load difference between all the APs in the load balancing group of this AP exceeds the threshold. If yes, the STA is not allowed to associate with this AP. The load difference can be configured as the number of STAs or the traffic.

To prevent the problem that the STA can receive signals from only one AP but fails to be associated due to load balancing, the maximum number of load balancing times can be configured. If association fails for consecutively twice due to load balancing, load balancing is not performed for the third time and the STA can be associated with the AP.

2.3.4 Inter-Radio Load Balancing

Inter-radio load balancing can balance the load among radios of the same AP to prevent overload of a single radio. Similarly, the load here can be the traffic or the number of associated STAs.

Working Principle

The principle of inter-radio load balancing is similar to that of load balancing group except that you can configure the load balancing thresholds respectively for intra-frequency radios (2.4 GHz or 5 GHz) or inter-frequency radios. The load ratio, that is, the radio weight ratio, can be configured for radios. The default radio weight is 100. For example, if weight of radio 1 is set to 50 and that of radio 2 is set to 100, the load ratio between radio 1 and radio 2 is 1:2. When load balancing is performed, load is balanced to radio 1 and radio 2 according to this load ratio.

2.3.5 Association Control

Association control is a method for controlling association behaviors of wireless STAs. STAs are divided into two groups. In each group, only one STA is defined as the primary STA, and the other STAs are defined as secondary STAs. The secondary STAs must follow the association behaviors of the primary STA. That is, the primary and secondary STAs must be associated with the same wireless network. In this way, association behaviors of wireless STAs can be properly controlled.

Working Principle

The coverage area of a wireless network is divided into several association control zones. One or several APs are deployed in each zone, and wireless terminals are divided into groups. The control zones that can be associated with the terminals are strictly controlled. For example, a school has many classrooms, and a wireless AP is deployed in each classroom. Radio signals travel in the space. When E-bags are used in two adjacent classrooms at the same time, the ideal condition is that all the teacher and student terminals are associated with the AP of their own classrooms so that the two classrooms will not interfere with each other. In this case, a classroom must be defined as an association control zone and all the teacher and student terminals in a classroom must be associated with the AP of the classroom.

Association control aims to prevent terminals from associating with a wireless network at random when multiple wireless networks are available for selection. The following are prerequisites for network configurations:

- Based on the pre-configured association control zones and package information, the AC pushes the information about primary STAs in all packages to all APs in the association control zones and generates a whitelist of primary STAs on these APs.

- The information about primary STAs in all packages is available in the AP whitelist. Therefore, before the association control function is enabled, the primary STA must associate itself with the corresponding SSID in the specified control zone. After that, the AC pushes all corresponding secondary STAs to all APs in the association control zone and generates a whitelist according to the configuration of the primary STA package to allow the secondary STAs to associate themselves with the control zone.
- When the primary STA is de-associated from the control zone, all the secondary STAs will also be de-associated and deleted from the AP whitelist.
- The above process can be summarized as follows: The secondary STAs must follow the primary STA to associate themselves with an AP in the same control zone, with which the primary STA is associated. Only the APs of this control zone have a whitelist of the corresponding secondary STAs. This ensures that STAs are not randomly associated with APs.

2.3.6 STA Management

STA management is used to manage association and disassociation logic processing of STAs.

Working Principle

In normal cases, an STA sends a disassociation frame to inform the AC that the STA is disassociated. If the STA does not send a disassociation frame to the AC when it is disassociated abnormally (for example, because the user removes the network interface card (NIC)), the AC cannot learn the disassociation of the STA. In this case, the AC detects the STA traffic and finds that the STA has no traffic within a period of time, and concludes that the STA had been disassociated. Then, the AC performs disassociation processing on the STA.

2.3.7 STA Informational Syslog Suppression

STA informational syslog suppression prevents a high CPU usage caused by the large number of informational syslogs generated when STAs are frequently associated or disassociated.

Working Principle

The number of syslogs output per second is counted. When this number reaches the upper limit, no more syslog is output within the second, thereby suppressing the syslog. In the next second, the number of syslogs is counted again.

2.3.8 STA Jitter Prevention

The STA jitter prevention function is used to retain an STA entry on the AC for a period of time after an STA is disassociated. In this time period, if the STA goes online from the same WLAN of the AP again, it is regarded that the STA has never gone offline. If the STA goes online from the same WLAN of another AP, it is regarded that the STA roams to the AP with the same SSID. If the STA goes online from another WLAN, it is regarded that the STA is switched to another AP with a different SSID. If the AP or authentication server proactively forces an STA to go offline, the STA jitter prevention function does not take effect and the STA goes offline immediately.

The STA jitter prevention function enables an STA to perform L3 roaming, preventing a roaming failure caused by a disassociation request proactively sent by the STA in the coverage hole.

Working Principle

After the STA jitter prevention function is enabled and an STA is disassociated, the AC adds the STA to the offline queue and starts a timer according to the expected deletion time specified based on the jitter prevention time. If the STA re-associates with an AP before the timer expires, the AC removes the STA from the offline queue and regards it as an online STA. Otherwise, the AC forces the STA to go offline when the timer expires.

2.3.9 Intelligent SSID Hiding

When the number of STAs on an AP or a radio reaches the upper limit, new STAs are not allowed to go online but the STAs can still scan the SSID and attempt to perform association. After the intelligent SSID hiding function is enabled, new STAs cannot detect the signal and will not attempt to perform association.

Working Principle

When the number of STAs on an AP or a radio reaches the upper limit, the beacon frame sent by the AP does not carry the SSID. When a new STA sends a probe request, the AP does not respond with a probe response.

2.4 Configuration

Configuration	Description and Command	
Configuring Dynamic Blacklist	(Mandatory) It is used to enable the dynamic blacklist function.	
	sta-blacklist enable	Enables the dynamic blacklist function.
	(Optional) It is used to configure the parameters of the dynamic blacklist.	
	sta-blacklist lifetime	Configures the lifetime of the dynamic blacklist.
	sta-blacklist detect-time	Configures the detection time of the dynamic blacklist.
	sta-blacklist fail-limit	Configures the maximum number of association failures.
Configuring STA Limit	(Optional) It is used to configure the maximum number of STAs.	
	sta-limit	Configures the maximum number of STAs.
	sta-limit radio	Configures the maximum number of STAs that can be associated with a radio of the AP.
Configuring Load Balancing	(Mandatory) It is used to configure load balancing.	
	num-balance-group create	Creates a number-based balancing group.

	num-balance-group add	Adds an AP to the number-based balancing group.
	num-balance-group del	Deletes an AP from the number-based balancing group.
	flow-balance-group create	Creates a traffic-based balancing group.
	flow-balance-group add	Adds an AP to the traffic-based balancing group.
	flow-balance-group del	Deletes an AP from the traffic-based balancing group.
	(Optional) It is used to configure the load balancing parameters.	
	num-balance-group num	Configures the threshold of the number-based balancing group.
	num-balance-group mode	Configures the working mode of the number-based balancing group.
	flow-balance-group flow	Configures the threshold of the traffic-based balancing group.
	flow-balance-group radio-flow	Enables a specified traffic balancing group to use the traffic uploaded by APs.
Configuring Inter-Radio Load Balancing	(Mandatory) It is used to enable the load balancing function among radios.	
	inter-radio-balance flow-balance enable	Enables inter-radio traffic-based balancing.
	inter-radio-balance num-balance enable	Enables inter-radio number –based balancing.
	(Optional) It is used to configure the load balancing parameters.	
	inter-radio-balance flow-balance dual-band	Configures parameters for traffic –based balancing among inter-frequency radios.
	inter-radio-balance flow-balance same-band	Configures parameters for traffic –based balancing among intra-frequency radios.
	inter-radio-balance num-balance dual-band	Configures parameters for number-based balancing among inter-frequency radios.
	inter-radio-balance num-balance same-band	Configures parameters for number-based balancing among intra-frequency radios.

Configuring Association Control	(Mandatory) It is used to enable the association control function.	
	package	Configures a package.
	primary-sta	Configures the primary STA in the package.
	secondary-sta	Configures the secondary STA in the package.
	control-zone	Configures an association control zone.
	ap	Configures the AP information.
	assoc-control	Enables association control.
Configuring STA Management	(Optional) It is used to configure the time after which the STA is disassociated if no traffic is detected.	
	sta-idle-timeout	Configures the time after which the STA is disassociated if no traffic is detected.
Configuring STA Informational Syslog Suppression	(Optional) It is used to configure the maximum output rate of the STA informational syslogs.	
	sta-logging rate-limit	Configures the maximum output rate of the STA informational syslogs.
Configuring STA Jitter Prevention	(Optional) It is used to set the jitter prevention time.	
	prevent-jitter enable	Enables the STA jitter prevention function.
	prevent-jitter time keep-time	Configures the STA jitter prevention time.
Configuring Intelligent SSID Hiding	**hide-ssid sta-reach-limit** [**radio** { **2.4g** | **5g** }]	Configures the intelligent SSID hiding function.

2.4.1 Configuring Dynamic Blacklist

Configuration Effect

- When it is detected that the number of association failures on an STA reaches the threshold within the specified time, this STA is added to the blacklist.

Notes

- The time period is not fixed and is between **detect-time** and (**detect-time** + 5).**detect-time** is expressed in second. This factor must be considered during configuration.

- If multiple authentication modes are applied, the number of STA association failures increases by 1 so far as one of the authentication modes fails. Combinations of authentication modes include, but are not limited to, PSK+Web, PSK+MAB+Web, PSK+MAB, MAB+Web, and 802.1x+Web.

Configuration Steps

Enabling Dynamic Blacklist

- (Mandatory) Enable the dynamic blacklist function on an AC or a fat AP.

Command	**sta-blacklist enable**
Parameter Description	N/A
Defaults	The blacklist function is disabled.
Command Mode	AC configuration mode
Usage Guide	N/A

Configuring the Dynamic Blacklist Parameters

- (Optional) Configure the dynamic blacklist parameters on an AC or a fat AP.
- Configure the blacklist lifetime.
- Run the **sta-blacklist lifetime** command to configure the lifetime of the dynamic blacklist. A longer lifetime indicates a longer period of time within which the STA added to the blacklist is not allowed to associate itself with the AC.
- Run the **sta-blacklist detect-time** command to configure the detection time. As the detection time decreases, the unauthorized STA detection becomes more sensitive and the number of false reports increases.
- Run the **sta-blacklist fail-limit** command to configure the upper limit of association failures. A larger upper limit indicates that an STA can make more association attempts.

Command	**sta-blacklist lifetime** *seconds*
Parameter Description	*seconds:* Indicates the blacklist lifetime. The value ranges from 60s to 1200s.
Defaults	300s
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**sta-blacklist detect-time** *seconds*
Parameter Description	*seconds:* Indicates the STA detection time. The value ranges from 5s to 60s.
Defaults	60s
Command Mode	AC configuration mode

Usage Guide	This command is used to configure the STA detection time. When encountering the first association failure, the STA is listed as a suspected attacker. If the number of association failures on the STA reaches the upper limit (namely, the **fail-limit**) within the detection time, the STA is added to the blacklist.

Command	**sta-blacklist fail-limit** *number*
Parameter Description	*number*: Indicates the maximum number of association failures. The value ranges from 1 to 100.
Defaults	5
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Run the **show sta-blacklist** command to display the STAs in the blacklist.

Configuration Example

Configuring Dynamic Blacklist

Scenario **Figure 2-4**	Configuration Steps	● Configure the dynamic blacklist function.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# ac-controller AC(config-ac)# sta-blacklist enable
Verification	● After the CAPWAP tunnel is established between an AP and an AC, enter an incorrect password for several times to verify that the STA can be added to the blacklist.
AC	AC# show sta-blacklist

	Num STA MAC Add time ---------- -------------- -------------------- 1 0080.1111.1111 2013-07-02 13:56:22 2 0090.2222.3333 2013-07-02 13:56:35 3 0070.1111.2233 2013-07-02 13:57:08

Common Errors

- N/A

2.4.2 Configuring STA Limit

Configuration Effect

- Limit the maximum number of STAs that can be associated with an AC, a WLAN, an AP, or a radio of an AP on the wireless network.

Notes

- The STA limits configured for an AC, a WLAN, an AP, or a radio of an AP take effect simultaneously. That is, an STA can be associated only if all the STA limits are met.
- The STA limit configured on the AC is subject to the license.

Configuration Steps

↘ Configuring STA Limit

- (Optional) Configure the STA limitation an AC or a fat AP.
- If the number of STAs on the wireless network is large, the STA limit can be configured to allow more STAs are associated, but the total bandwidth will decrease.
- Run the **sta-limit** command to configure the STA limit. A large STA limit indicates that more STAs can be associated.
- The AC-based STA limit is (32 x Number of APs) by default. The WLAN-based STA limit is not specified by default. The AP-based STA limit is 32 by default.
- Run the **sta-limit radio** command to configure the radio-based STA limit for an AP. A large STA limit indicates that more STAs can be associated.
- Run the **sta-limit per-ap** command to configure the maximum number of STAs supported on each AP in a WLAN. By default, the number of STAs on an AP is not limited. If the number of configured STAs exceeds the maximum number of STAs supported by an AP, no new STA can associate with the AP.

Command	**sta-limit** *max-num*
Parameter Description	*max-num*: Indicates the maximum number of STAs. The value varies according to the configuration mode and device.

Defaults	In AC configuration mode, the default value is (32 x Number of APs supported by the AC), depending on the license. In AP group configuration mode, the default value is 32. In AP configuration mode, the default value is 32 for a disassociated AP or in the **ap-config all** configuration mode. The default value for an associated AP is determined by the AP model. In WLAN configuration mode, the STA limit is not specified.
Command Mode	AC configuration mode, WLAN configuration mode, AP configuration mode, or AP group configuration mode
Usage Guide	If the maximum number of STAs configured for a disassociated AP exceeds the actual capacity, the STA limit automatically changes to the actual maximum number of STAs supported after the AP is associated.

Command	**sta-limit** *max-num* **radio** *radio-id*
Parameter Description	*max-num*: Indicates the maximum number of STAs. The value ranges from 1 to 156. *radio-id*: Indicates the radio ID. The value ranges from 1 to 32.
Defaults	The STA limit is not specified by default.
Command Mode	AP configuration mode AP group configuration mode
Usage Guide	If the maximum number of STAs configured for a disassociated AP exceeds the actual capacity of the radio, the STA limit automatically changes to the actual maximum number of STAs supported after the AP is associated.

Command	**sta-limit per-ap** *max-num*
Parameter Description	*max-num*: Indicates the maximum number of STAs supported on an AP. The value ranges from 1 to 1536.
Defaults	By default, the number of STAs supported on an AP is not limited.
Command Mode	WLAN configuration mode
Usage Guide	N/A

Verification

- Verify that the number of STAs is limited.

Configuration Example

Configuring STA Limit

Scenario **Figure 2-5**	Configuration Steps	● Configure the STA limit.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# ap-config ap1 AC(config-ap)# sta-limit64
Verification	● After the CAPWAP tunnel is established between an AP and an AC, check the AC running configuration.
AC	AC# show ap-config running ap-config ap1 sta-limit 64 !

Common Errors

- N/A

2.4.3 Configuring Load Balancing

Configuration Effect

- Enable even distribution of STAs on multiple APs in a load balancing group.

Notes

- Load balancing is applicable only to STAs that are associated, but not to STAs that are disassociated. Therefore, after STAs are disassociated, the traffic difference between APs or the STA quantity difference may exceed the threshold.
- Load balancing takes effect only on the same type of radios (2.4 GHz or 5 GHz). If the types of radios are different, load balancing is performed only when the AP reports that the STAs are capable of dual-band operation. Otherwise, the 2.4 GHz STAs may fail to be associated with 2.4 GHz radios when no STA is associated with 5 GHz radio.

- After the traffic-based balancing group is configured to use the traffic information uploaded by APs, APs must upload the traffic information to the AC at a regular interval because the traffic only exists on APs and is not routed to the AC. During this interval, the traffic information on the AC does not change. At this time, if the traffic between APs is not balanced, STAs cannot be associated with APs with heavy traffic until the APs upload the traffic information to the AC.

Configuration Steps

Creating a Number-based Balancing Group

- (Mandatory)Create a number-based balancing group on the AC.
- APs can be only added to a created load balancing group.

Command	**num-balance-group create** *group-name*
Parameter Description	*group-name*: Indicates the name of a load balancing group.
Defaults	No number-based balancing group is created.
Command Mode	AC configuration mode
Usage Guide	N/A

Adding an AP to the Number-based Balancing Group

- (Mandatory) The configuration is performed on the AC.
- Load balancing applies to the APs which are added to the load balancing group.

Command	**num-balance-group add** *group-name ap-name*
Parameter Description	*group-name*: Indicates the name of a load balancing group. *ap-name*: Indicates the AP name.
Defaults	No AP is added to the number-based balancing group.
Command Mode	AC configuration mode
Usage Guide	N/A

Creating a Traffic-based Balancing Group

- (Mandatory) The configuration is performed on the AC.
- APs can be only added to a created load balancing group.

Command	**flow-balance-group create** *group-name*
Parameter Description	*group-name*: Indicates the name of a load balancing group.
Defaults	No traffic-based balancing group is created.
Command Mode	AC configuration mode
Usage Guide	N/A

Adding an AP to the Traffic-based Balancing Group

- (Mandatory) The configuration is performed on the AC.
- Load balancing applies to the APs which are added to the load balancing group.

Command	**flow-balance-group add** *group-name ap-name*
Parameter Description	*group-name*: Indicates the name of a load balancing group. *ap-name*: Indicates the AP name.
Defaults	No AP is added to the traffic-based balancing group.
Command Mode	AC configuration mode
Usage Guide	N/A

Configuring Parameters of Load Balancing Group

- (Optional) Configure the parameters of load balancing group on the AC.
- Run the **num-balance-group num** command to configure the threshold of number-based balancing group. A larger threshold indicates a greater difference in the number of STAs associated with two APs, and the less balanced load.
- Run the **num-balance-group mode** command to configure the radio-based balancing function. If radio-based balancing is enabled, the control on the distribution of STAs is more accurate, but the effect of balancing among APs is less satisfying.
- Run the **num-balance-group enable** command to configure the trigger threshold of the number-based balancing group. A higher trigger threshold indicates that load balancing is enabled only when the AP load is heavy.
- Run the **num-balance-group del** command to delete an AP from the number-based balancing group.
- Run the **flow-balance-group flow** command to configure the traffic-based balancing threshold. A higher traffic balancing threshold indicates that the traffic difference between two APs is greater and the traffic is less balanced.
- Run the **flow-balance-group radio-flow** command to enable the traffic balancing group to use the traffic information uploaded by APs. In local forwarding mode, data packets are not routed to the AC, and the AC cannot obtain the traffic information. Therefore, the traffic information uploaded by APs must be used to determine whether to enable load balancing.
- Run the **flow-balance-group enable** command to configure the trigger threshold of the traffic-based balancing group. A higher trigger threshold indicates that load balancing is enabled only when the AP load is heavy.
- Run the **flow-balance-group del** command to delete an AP from the traffic-based balancing group.
- Run the **flow-balance-group base** command to configure the baseline of traffic balancing in global configuration mode.
- Run the **sta-balance num-limit enable** command to limit the maximum times of load balancing.

Command	**num-balance-group num** *group-name number*
Parameter Description	group-name: Indicates the name of a load balancing group. number: Indicates the trigger threshold. The default value is 3. The value ranges from 0 to 20, where 0 indicates that the number balancing function is disabled for the load balancing group.
Defaults	3

Command Mode	AC configuration mode
Usage Guide	N/A

Command	**num-balance-group mode** *group-name*{ **radio-mode**| **ap-mode** }
Parameter Description	*group-name:* Indicates the name of a load balancing group.
Default s	AP-based number balancing
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**num-balance-group enable** *group-name number*
Parameter Description	*group-name:* Indicates the name of a load balancing group. *number*: indicates the trigger threshold. The default value is 3. The value ranges from 0 to 10, where 0 indicates that the number balancing function is disabled for the load balancing group.
Defaults	3
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**num-balance-group del** *group-name ap-name*
Parameter Description	*group-name*: Indicates the name of a load balancing group. *ap-name*: Indicates the AP name.
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**flow-balance-group flow** *group-name number*
Parameter Description	*group-name:* Indicates the name of a load balancing group. *number*: indicates the trigger threshold. The unit is %. The default value is 5%. The value ranges from 0 to 1000, where 0 indicates that the load balancing function is disabled for the load balancing group. The percentage baseline is 10 Mbps by default.
Defaults	5%
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**flow-balance-group radio-flow** *group-name*
Parameter Description	*group-name:* Indicates the name of the traffic balancing group.
Defaults	Traffic information on the CAPWAP data channel is used on the AC.
Command Mode	AC configuration mode
Usage Guide	You can enable a traffic balancing group to use the traffic information uploaded by APs. In this way, the traffic balancing group can receive the traffic information periodically sent by APs for load balancing.

Command	**flow-balance-group enable** *group-name number*
Parameter Description	*group-name:* Indicates the name of a load balancing group. *number*: Indicates the trigger threshold. The unit is %. The default value is 5%. The value ranges from 0 to 500, where 0 indicates that the load balancing function is disabled for the load balancing group. The percentage baseline is 10 Mbps by default.
Defaults	5%
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**flow-balance-group del** *group-name ap-name*
Parameter Description	*group-name:* Indicates the name of a load balancing group. *ap-name:* Indicates the AP name.
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**flow-balance-group base** *number*
Parameter Description	*number*: Indicates that traffic baseline. The default value is 10 Mbps. The value ranges from 1 to 100.
Defaults	10 Mbps
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**sta-balance num-limit enable**

Parameter Description	N/A
Defaults	The function is disabled by default.
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Number balancing: Check whether the difference in the number of STAs associated with APs in the load balancing group is within the threshold.
- Traffic balancing: Check whether the difference in the traffic of APs in the load balancing group is within the threshold.

Configuration Example

Configuring Traffic Balancing

Scenario **Figure 2-6**	Configuration Steps	● Create a load balancing group. ● Set the trigger threshold of this load balancing group to 1000 Kbps. ● Add AP1 and AP2 to the load balancing group named **test-group.** (If two APs are added to the same load balancing group, PCs in this group can search the RF signals of all APs.)
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)#ac-controller AC(config-ac)#flow-balance-group create test-group AC(config-ac)#flow-balance-group flow test-group 10 AC(config-ac)#flow-balance-group add test-group AP1

	AC(config-ac)#flow-balance-group add test-group AP2
Verification	● Check the configuration of the load balancing group.
AC	AC# show ac-config flow-balance summary Group State Enable Threshold Base mode AP NAME --- --- --- --- --- --- test-group UP 5*100kbps 10% 10 ap-mode(0) AP1, AP2

Common Errors

- N/A

2.4.4 Configuring Inter-Radio Load Balancing

Configuration Effect

- Enable inter-radio load balancing on APs to balance the load among radios.
- Configure the load ratio of radios. Load between radios is balanced according to the ratio.

Notes

- This function is not applicable to the i-Share solution. Signals of different radios cover different areas. An STA may receive signals from one or several radios. In this case, the inter-radio load balancing function cannot be enabled.
- Load balancing is applicable only to STAs that are associated. Therefore, after STAs are disassociated, the traffic difference between APs or the STA quantity difference may exceed the threshold.
- If the radio that an STA attempts to associate with is different from the radio with the lowest load, load balancing is performed only when the AP reports that the STA is capable of dual-band operation. Otherwise, the 2.4 GHz STAs may fail to be associated with 2.4 GHz radios when no STA is associated with 5 GHz radio.
- After the traffic balancing group is configured to use the traffic information uploaded by APs, APs must upload the traffic information to the AC at a regular interval because the traffic only exists on APs in local forwarding mode. During this interval, the traffic information on the AC does not change. At this time, if the traffic between APs is not balanced, STAs cannot be associated with APs with heavy traffic until the APs upload the traffic information to the AC.
- Configuration of load balancing parameters varies according to the inter-frequency and intra-frequency radios.
- When performing load balancing, determine the load balancing parameter according to the target radio and the type of the radio associated with the STA. Then, determine whether to associate the STA to the target radio. For a specific AP, so far as load balancing is enabled in any of the ap-config, ap-group, and ap-config all modes, load balancing is enabled on this AP. If the load balancing configurations in the three modes are different, the configurations take effect in the following sequence: ap-config > ap-group > ap-config all.

- When inter-radio load balancing is enabled, the association attempt of the same STA will be denied for at most twice within five minutes. If the STA is still associated with a radio with a heavy load for the third time, the association is allowed. Therefore, the effect of inter-radio load balancing is related to the actual STA behaviors.

Configuration Steps

Enabling Inter-radio Traffic Balancing

- (Mandatory). The configuration is performed on the AC. After the function is enabled, traffic is balanced whenever possible among different radios of the same AP.
- This function can be enabled for a single AP, all APs in an AP group, or all APs (configured in ap-config all mode).

Command	**inter-radio-balance flow-balance enable**
Parameter Description	N/A
Defaults	Inter-radio traffic balancing is disabled.
Command Mode	AP configuration mode, AP group configuration mode
Usage Guide	N/A

Enabling Inter-radio Number Balancing

- (Mandatory)The configuration is performed on the AC. After the function is enabled, the number of STAs is balanced whenever possible among different radios of the same AP.
- This function can be enabled for a single AP, all APs in an AP group, or all APs (configured in ap-config all mode).

Command	**inter-radio-balance num-balance enable**
Parameter Description	-
Defaults	Inter-radio number balancing is disabled.
Command Mode	AP configuration mode, AP group configuration mode
Usage Guide	N/A

Configuring Inter-radio Load Balancing Parameters

- (Optional) The configuration is performed on the AC. Parameters can be adjusted based on actual requirements of network optimization.
- Run the **inter-radio-balance flow-balance dual-band enable-load** *en-num* **threshold** *thrs-num* command to configure the trigger threshold and the load threshold for traffic balancing among inter-frequency radios. A smaller trigger threshold indicates that it is easier to enable load balancing. A smaller load threshold indicates that the load is better balanced.
- Run the **inter-radio-balance flow-balance same-band enable-load** *en-num* **threshold** *thrs-num* command to configure the trigger threshold and the load threshold for traffic balancing among intra-frequency radios. A smaller trigger threshold indicates that it is easier to enable load balancing. A smaller load threshold indicates that the load is better balanced.

- Run the **inter-radio-balance num-balance dual-band enable-load** *en-num* **threshold** *thrs-num* command to configure the trigger threshold and the load threshold for number balancing among inter-frequency radios. A smaller trigger threshold indicates that it is easier to enable load balancing. A smaller load threshold indicates that the load is better balanced.
- Run the **inter-radio-balance num-balance same-band enable-load** *en-num* **threshold** *thrs-num* command to configure the trigger threshold and the load threshold for number balancing among intra-frequency radios. A smaller trigger threshold indicates that it is easier to enable load balancing. A smaller load threshold indicates that the load is better balanced.

Command	**inter-radio-balance flow-balance dual-band enable-load** *en-num* **threshold** *thrs-num*
Parameter Description	en-num: Indicates the trigger threshold. The unit is 100 kbps. The value ranges from 1 to 1000. thrs-num: Indicates the load threshold. The unit is 100 Kbps. The value ranges from 1 to 1000.
Defaults	By default, both the trigger threshold and the load threshold are 10.
Command Mode	AP configuration mode, AP group configuration mode
Usage Guide	N/A

Command	**inter-radio-balance flow-balance same-band enable-load***e n-num* **threshold** *thrs-num*
Parameter Description	en-num: Indicates the trigger threshold. The unit is 100 kbps. The value ranges from 1 to 1000. thrs-num: Indicates the load threshold. The unit is 100 Kbps. The value ranges from 1 to 1000.
Defaults	By default, both the trigger threshold and the load threshold are 5.
Command Mode	AP configuration mode, AP group configuration mode
Usage Guide	N/A

Command	**inter-radio-balance num-balance dual-band enable-load** *en-num* **threshold** *thrs-num*
Parameter Description	en-num: Indicates the trigger threshold. The value ranges from 1 to100. thrs-num: Indicates the load threshold. The value ranges from 1 to 100.
Defaults	By default, both the trigger threshold and the load threshold are 8.
Command Mode	AP configuration mode, AP group configuration mode
Usage Guide	N/A

Command	**inter-radio-balance num-balance same-band enable-load** *en-num* **threshold** *thrs-num*
Parameter Description	en-num: Indicates the trigger threshold. The value ranges from 1 to 100. thrs-num: Indicates the load threshold. The value ranges from 1 to 100.
Defaults	By default, both the trigger threshold and the load threshold are 20 and 6 respectively.
Command Mode	AP configuration mode, AP group configuration mode

Usage Guide	N/A

Configuring the Load Ratio of Radios

- (Optional) The configuration is performed on the AC. After the load ratio is configured, load is balanced to different radios of the same AP based on the ratio.
- The load ratio can be configured for a single AP, all APs in an AP group, or all APs (ap-configure all configuration mode).

Command	**inter-radio-balance radio** *radio-id* **weight** *weight-num*
Parameter Description	N/A
Defaults	The radio weight is 100, and load is balanced between radios based on the 1:1 ratio by default.
Command Mode	AP configuration mode, AP group configuration mode
Usage Guide	N/A

Verification

- Number balancing: Run the **show ap-config summary** command to check whether the difference in the number of STAs between radios of the AP where load balancing is within the threshold.
- Traffic balancing: Run the **show ac-config client** command to check whether the traffic difference between radios of the AP where load balancing is enabled is within the threshold.

Configuration Example

Enabling Inter-radio Number Balancing on All APs in the Default AP Group

Scenario Figure 2-7	Configuration Steps	● Enter the default AP group configuration mode. ● Enable inter-radio number balancing.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)#ap-group default AC(config-group)#inter-radio-balance num-balance enable

Verification	• Run the **show run** command and check the configurations.
AC	AC# show run | begin ap-group default ap-group default inter-radio-balance num-balance enable

Common Errors

- N/A

2.4.5 Configuring Association Control

Configuration Effect

- Secondary STAs must be associated with APs in the same group as the primary STA when being associated.

Notes

- When a package is deleted, all its related configurations are deleted as well. If some STAs in this package are currently associated, all these STAs will be disassociated.
- A package can only be configured with one primary STA. If the information about the primary STA in the package is configured for multiple times, the latest configuration prevails.
- When a primary STA is deleted from a package, the primary STA and all secondary STAs in this package may be disassociated.
- When a secondary STA is deleted from a package, this secondary STA may be disassociated.
- The association control zone name cannot be duplicated; otherwise, an error will be prompted. In addition, if an association control zone is deleted, all configurations related to this zone will be deleted. Consequently, STAs in the package associated with this control zone may be disassociated.
- When the AP information in an association control zone is deleted, STAs in the package associated with this AP be disassociated.

Configuration Steps

↘ Configuring a Package

- (Mandatory) The configuration is performed on an AC or a fat AP.
- The primary and secondary STA information can be configured only after a package is configured.

Command	**package** *pkg-name*
Parameter Description	*pkg-name*: Indicates the name of a package. The package name is a string of 1 to 32 characters.
Defaults	No package is configured by default.
Command Mode	Global configuration mode

Usage Guide	N/A

Configuring the Primary and Secondary STAs in a Package

- (Mandatory) The configuration is performed on an AC or a fat AP.
- Run the **primary-sta** command to configure the primary STA. Only one primary STA can be configured. The secondary STAs will be associated with APs in the same group as the primary STA.
- Run the **secondary-sta** command to configure a secondary STA. After the secondary STA is configured, the secondary STA will be associated with an AP in the same group as the primary STA.

Command	**primary-sta** *mac-address*
Parameter Description	*mac-address*: Indicates the MAC address of the STA.
Defaults	No primary STA is configured by default.
Command Mode	Package configuration mode
Usage Guide	N/A

Command	**secondary-sta** *mac-address*
Parameter Description	*mac-address*: indicates the MAC address of the STA.
Defaults	No secondary STA is configured by default.
Command Mode	Package configuration mode
Usage Guide	-

Configuring an Association Control Zone

- (Mandatory) The configuration is performed on an AC or a fat AP.
- Configure an association control zone.
- APs can be added to an association control zone only after this association control zone is configured.

Command	**control-zone** *czone-name*
Parameter Description	*czone-name*: Indicates the name of an association control zone. The name is a string of 1 to 64 characters.
Defaults	No association control zone is configured by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Adding an AP to an Association Control Zone

- (Mandatory) The configuration is performed on an AC or a fat AP.

- Add an AP to an association control zone.
- Association control can be performed on only APs that are added to the association control zone.

Command	**ap** *WORD*
Parameter Description	*WORD*: Indicates the name of an AP. The name is a string of 1 to 64 characters.
Defaults	No AP is added to an association control zone by default.
Command Mode	Association control zone configuration mode
Usage Guide	N/A

Enabling the Association Control Function

- (Mandatory) The configuration is performed on an AC or a fat AP.The **assoc-control** command must be used to enable the association control function.
- Enable the association control function.

Command	**assoc-control**
Parameter Description	N/A
Defaults	The association control function is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Verify that secondary STAs can be associated with APs in the same group as the primary STA.

Configuration Example

Configuring the E-bag in Fit AP Structure.

Scenario **Figure 2-8**	Configuration Steps	● Configure packages and related primary STAs and secondary STAs. ● Configure association control zones and related APs. ● Enable the association control function.
AC	AC#configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# package Cart 1 AC(config-package)#primary-sta 00d0.f800.0001 AC(config-package)#secondary-sta 00d0.f800.0002 AC(config-package)#secondary-sta 00d0.f800.0003 AC(config-package)#exit AC(config)# control-zone Classroom 1 AC(config-czone)#apAP1 AC(config-czone)#exit AC(config)# control-zone Classroom 2 AC(config-czone)# apAP2 AC(config-czone)#exit AC(config)#assoc-control
Verification	● Display the association control running state. ● Display the package configuration. ● Display the association control zone configurations.

AC	AC#show assoc-control Association control is enabled. AC# show package total package num : 1 ========= Cart 1 ========= primary STA : 00d0.f800.0001 secondary STA num : 2 00d0.f800.0002 00d0.f800.0003 AC# show control-zone control zone num : 2 control-zoneAP ------------ ---------- Classroom 1 AP1 00d0.f800.889e Classroom 2 AP2 00d0.f800.889f

Common Errors

- N/A

2.4.6 Configuring STA Management

Configuration Effect

- STAs are disassociated if no traffic is detected on the STAs within the specified time.

Notes

- N/A

Configuration Steps

Configuring the STA Aging Time

- (Optional) The configuration is performed on an AC or a fat AP.
- A shorter time configured indicates that an STA without traffic can be detected and disassociated in a faster manner.

Command	**sta-idle-timeout** *value*
Parameter Description	*value*: Indicates the aging time in second. The value ranges from 60 to 86400.
Defaults	300s

Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Check whether the STA aging time is successfully configured.

Configuration Example

Configuring the STA Aging Time

Scenario **Figure 2-9**	Configuration Steps	● Configure the STA aging time.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# ap-config ap1 AC(config-ap)# sta-idle-timeout 15
Verification	● After the CAPWAP tunnel is established between an AP and an AC, check the configuration information.
AC	AC# show ap-config running ap-config ap1 sta-idle-timeout 15 !

Common Errors

- N/A

2.4.7 Configuring STA Informational Syslog Suppression

Configuration Effect

- Even STAs are frequently associated or disassociated, the number of informational syslogs output per second does not exceed the limit.

Notes

- N/A

Configuration Steps

Configuring the Syslog Suppression Rate

- (Optional) The configuration is performed on the AC.
- Configure the syslog suppression rate. A larger rate configured indicates that more syslogs can be output per second.

Command	**sta-logging rate-limit** *limit-num*
Parameter Description	*limit-num*: Indicates the rate, which is expressed in records per seconds. The value ranges from 0 to 10000.
Defaults	By default, less than five syslog records are output per second, that is, the maximum syslog output rate is 5 records per second.
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to check whether the syslog suppression rate is successfully configured.

Configuration Example

Configuring the STA Informational Syslog Suppression Function

Scenario **Figure 2-10**	Configuration Steps	● Configure the STA informational syslog suppression function.

AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# ac-controller AC(config-ac)# sta-logging rate-limit 50
Verification	● After the CAPWAP tunnel is established between an AP and an AC, check the configuration information.
AC	AC# show running ac-controller sta-logging rate-limit 50 !

Common Errors

- N/A

2.4.8 Configuring STA Jitter Prevention

Configuration Effect

- After the STA jitter prevention function is enabled for a WLAN and an STA is disassociated from the WLAN, the AC retains an STA entry for a period of time before forcing the STA to go offline.

Notes

- When an AC or authentication server proactively forces an STA to go offline, the STA jitter prevention function does not take effect.

Configuration Steps

↘ Enabling the STA Jitter Prevention Function

- (Mandatory) Enable the STA jitter prevention function on the AC.

Command	**prevent-jitter enable**
Parameter Description	N/A
Defaults	The STA jitter prevention function is disabled by default.
Command Mode	WLAN configuration mode

Usage Guide	After the STA jitter prevention function is enabled for a WLAN and an STA is disassociated from the WLAN, the AC retains an STA entry for a period of time (60s by default) before forcing the STA to go offline.

Configuring the STA Jitter Prevention Time

- (Optional) Configure the STA jitter prevention time on the AC.

Command	**prevent-jitter time** *keep-time*
Parameter Description	*keep-time*: indicates the STA jitter prevention time in seconds. The value ranges from **1** to **86400**.
Defaults	60
Command Mode	WLAN configuration mode
Usage Guide	N/A

Verification

- Run the **show running** or **show ap-config running** command to check whether the configuration is successful.

Configuration Example

Enabling the STA Jitter Prevention Function

Scenario **Figure 2-11**	Configuration Steps	Enable the STA jitter prevention function.
AC	`AC# configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.` `AC(config)# wlan-config 1`

	AC(config-wlan)# prevent-jitter enable
Verification	Check the configuration information.
AC	AC# show running-config wlan-config 1 SSID prevent-jitter enable !

Common Errors

- N/A

2.4.9 Configuring Intelligent SSID Hiding

Configuration Effect

- When the number of STAs on an AP or a radio reaches the upper limit, new STAs cannot detect the SSID.

Notes

- This function takes effect only when both the AC and AP versions support this function.

Configuration Steps

↘ Enabling Intelligent SSID Hiding

- (Optional) The configuration is performed on the AC.
- Enable the intelligent SSID hiding function.

Command	**hide-ssid sta-reach-limit [radio { 2.4g | 5g }]**
Parameter Description	**radio**: indicates a specific radio on which the intelligent SSID hiding function is enabled. If this parameter is not specified, the intelligent SSID hiding function is enabled on all radios. **2.4g**: indicates that the intelligent SSID hiding function is enabled on the 2.4G radio. **5g**: indicates that the intelligent SSID hiding function is enabled on the 5G radio.
Defaults	The intelligent SSID function is disabled by default.
Command Mode	AP configuration mode
Usage Guide	After the intelligent SSID function is enabled and the numbers of STAs on all APs in an area reach the upper limit, new STAs cannot detect the SSID in this area.

Verification

- Run the **show running** or **show ap-config running** command to check whether the configuration is successful.

Configuration Example

Enabling Intelligent SSID Hiding Function

Scenario **Figure 2-12**	Configuration Steps	Enable the intelligent SSID hiding function.
AC	`AC# configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.` `AC(config)# ap-config AP1` `AC(config-ap)# hide-ssid sta-reach-limit`
Verification	After the CAPWAP tunnel is established between an AP and an AC, check the configuration information.
AC	`AC# show ap-config running AP1` `ac-config AP1` ` hide-ssid sta-reach-limit` `!`

Common Errors

- The AC version supports the intelligent SSID hiding function but the AP version does not.

2.5 Monitoring

Displaying

Description	Command
Displays the information about all STAs connected to the AC.	**show ac-config client** [**by-ap-name | 802.11a | 802.11b | 802.11n | 802.11g** | **802.11ac | 802.11ax | other**]
Displays the detailed information about a specified STA.	**show ac-config client detail** *mac-address*
Displays the statistics of all STAs.	**show ac-config client statistic**
Displays the detailed configuration of the traffic-based balancing group.	**show ac-config flow-balance summary**
Displays the detailed configuration of the number-based balancing group.	**show ac-config num-balance summary**
Displays the status of the association control function.	**show assoc-control**
Displays the association control zone configuration.	**show control-zone** [**summary** | *czone-name*]
Displays the package configuration.	**show package** [*pkt-name*]
Displays the STAs in the blacklist.	**show sta-blacklist**
Displays the 802.11ac wave2 information.	**show ac-config client 11ac-wave2**
Displays the backup information of an STA.	**show ac-config client hot-backup**

3 Configuring CAPWAP

3.1 Overview

Control And Provisioning of Wireless Access Points (CAPWAP) is a protocol proposed to address the issue of large-scale access point (AP) deployment on the wireless local area network (WLAN).

On a fit AP network, the access controller (AC) manages all APs in a unified manner through CAPWAP. The AC pushes control polices to specified APs, instead of configuring APs one by one. CAPWAP is used to set up the control channel and the data channel between an AP and an AC. The control channel is used by ACs to configure APs, or by APs to send event notifications to ACs. The data channel is used to exchange data packets between APs and ACs.

Protocols and Standards

- RFC5415: Control And Provisioning of Wireless Access Points (CAPWAP) Protocol Specification
- RFC5416: Control and Provisioning of Wireless Access Points (CAPWAP) Protocol Binding for IEEE 802.11
- RFC5417: Control And Provisioning of Wireless Access Points (CAPWAP) Access Controller DHCP Option

3.2 Applications

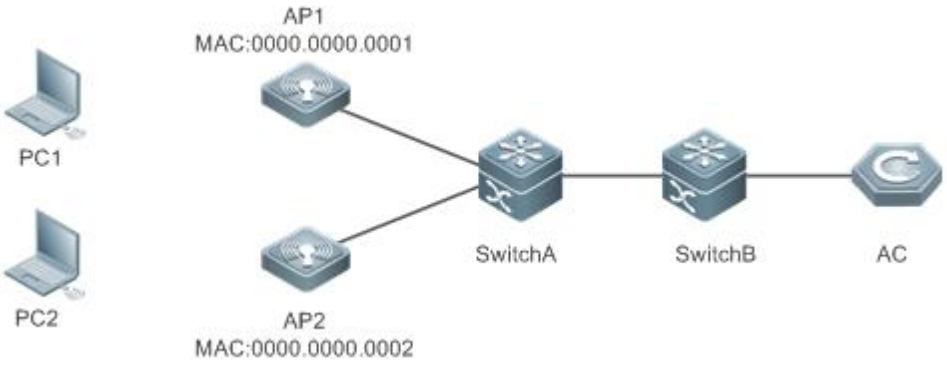
Application	Description
Dynamically Setting up a CAPWAP Tunnel	An AP accesses an AC through switches. The DCHP server is deployed on the switch connected to APs. The AP obtains the AC address dynamically through DHCP to set up a CAPWAP tunnel with the AC.
Statically Setting up a CAPWAP Tunnel	An AP accesses an AC through switches. The static IP address of the AC is configured on the AP. The AP sets up a CAPWAP tunnel with the AC based on the configured static IP address of the AC.
Upgrading APs	After a CAPWAP tunnel is set up between an AC and each AP, the AC upgrades APs in a large scale through CAPWAP.

3.2.1 Dynamically Setting up a CAPWAP Tunnel

Scenario

APs access the AC through switches. The DCHP server is deployed on the switch connected to APs. On the DHCP server, the DHCP address pool is configured and Option138 is pushed, where Option138 is the IP address of the AC. The AP obtains the AC address and sets up a CAPWAP tunnel with the AC. As shown in Figure 3-1, the AC, switches (SwitchA and SwitchB), and APs (AP1 and AP2) are connected with each other through the trunk ports. PC1 is connected to AP1, and PC2 is connected to AP2.

Figure 3-1



Deployment

- APs do not need to be configured one by one on a fit AP network. When an AP is powered on, the IP address must be obtained first. Therefore, a DHCP server must be deployed on the network. If the DHCP server is not deployed, the DHCP function of the AC is used to implement functions of the DHCP server.
- The AC communicates with the AP through the Layer3 (L3) switch, and the DHCP server must send Option138, which contains the IP address of the AC. After obtaining the IP address of the AC, the AP sets up a CAPWAP communication tunnel with the AC.
- On the AC, configure a loopback interface address, or run the **capwap ctrl-ip** *ip-address* command to configure the source address for setting up a CAPWAP tunnel.
- Configure a route to implement interworking between the AC and the IP address obtained by the AP.

3.2.2 Statically Setting up a CAPWAP Tunnel

Scenario

The AP sets up a CAPWAP tunnels with the AC based on the configured static IP address of the AC. An AP accesses an AC through switches. The topology is the same as that shown in Figure 3-1.

Deployment

- Configure the static IP addresses of ACs. The AP will send the Discover Request messages to these static IP addresses to check the effectiveness of ACs, and then select and join an AC.
- On the AC, configure a loopback interface address as the source address for setting up a CAPWAP tunnel.
- Configure a route to implement interworking between the AC and the IP address obtained by the AP.

3.2.3 Upgrading APs

Scenario

The AP obtains the AC address based on the configured static IP address of the AC or from the DHCP server, and sets up a CAPWAP tunnel with the AC. The AP accesses the AC through switches. The topology is the same as that shown in Figure 3-1.

Deployment

- On the AC, configure an IP interface address as the source address for setting up a CAPWAP tunnel.
- Configure a route to implement interworking between the AC and the IP address obtained by the AP.
- On the AC, activate the AP software that is stored locally.

3.3 Features

Basic Concepts

STA, AP, and AC

STA: It is a wireless workstation that is equipped with the wireless network interface card (NIC), such as a laptop computer or a mobile phone.

AP: It is a wireless access point that provides radio signals so that the STA can access the wireless network.

AC: It is a wireless access controller that provides wireless connection and related service functions.

Control Channel and Data Channel

Control channel: It is used by ACs to configure APs, or by APs to send event notifications to ACs.

Data channel: It is used to exchange data packets between APs and ACs.

AC Discovery

AC discovery phase: An AP can send a discover request message by means of broadcast, multicast, DHCP, DNS, or static configuration to detect ACs, select an optimum AC from one or more ACs, join the AC, and set up a CAPWAP session with the AC.

Datagram Transport Layer Security (DTLS)

The CAPWAP control channel uses the DTLS protocol for key negotiation and encryption.

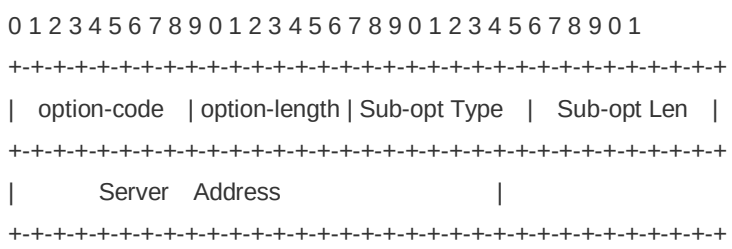
Option

The Option information sent by the DHCP server can carry the IPv4 or IPv6 address of an AC. The AP obtains the AC address from the Option information sent by the DHCP server.

The AP can obtain the IP address of an AC using Option 138 or Option 43, or obtain the IPv6 address of an AC using Option 52. When configuring the DHCP server of the AP, you must configure the related options to set the IP address of the AC; otherwise, the AP cannot discover the AC through DHCP discovery.

Option 138 and Option 52 are standard formats defined in RFC5417, and Option 43 is defined by vendors. Currently, Option 43 in the following formats can be analyzed:

Format 1: Assume that the IP address of a specified AC is 1.1.1.1. The corresponding configuration is Option 43 hex f10401010101.



option-code: indicates the option code. In this example, the option code is 43 in decimal format.

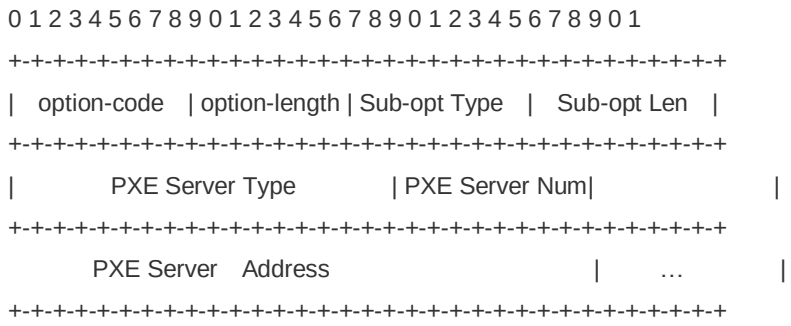
option-length: indicates the length of the option data, which excludes option-code and option-length.

Sub-opt Type: indicates the sub-option type. In this example, the sub-option type is 0xF1, that is, 241 in decimal format.

Sub-opt Len: indicates the length of the sub-option, which is equal to (Number of addresses x 4).

Server Address: indicates the server address.

Format 2: Assume that the IP address of a specified AC is 1.1.1.1. The corresponding configuration is option 43 hex 800700000101010101.



option-code: indicates the option code. In this example, the option code is 43 in decimal format.

option-length: indicates the length of the option data, which excludes option-code and option-length.

Sub-opt Type: indicates the sub-option type. In this example, the sub-option type is 0x80, that is, 128 in decimal format.

Sub-opt Len: indicates the length of the sub-option, which is equal to (Number of addresses x 4 +3).

Server Type: indicates the server type. The value is 0x0000.

Server Num: indicates the number of server addresses.

Server Address: indicates the server address.

Format 3: Assume that the IP address of a specified AC is 1.1.1.1. The corresponding configuration is option 43 hex 01010101.

```
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|   option-code   | option-length | Server   Address            |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|       Server   Address           |               …   |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

option-code: indicates the option code. In this example, the option code is 43 in decimal format.

option-length: indicates the length of the option data, which excludes option-code and option-length.

Server Address: indicates the server address.

Overview

Feature	Description
Discovering an AC by an AP	The AP discovers potential ACs.
Joining an AC by an AP	The AP selects an optimum AC from one or more ACs, joins the AC, and sets up a CAPWAP tunnel with the AC.
Upgrading APs	After a CAPWAP tunnel is set up between an AC and each AP, the AC upgrades APs in a large scale.
Forwarding Data on the Tunnel	After a CAPWAP tunnel is set up between an AC and each AP, data packets can be exchanged through the data channel.

3.3.1 Discovering an AC by an AP

An AP discovers potential ACs by sending a Discovery Request message.

Working Principle

As soon as an AP is connected to the network, the AP enters the process of discovering ACs. The AP sends a Discovery Request message by means of broadcast, multicast, or unicast If unicast is used, the AP obtains the AC IP address list through the DHCP server, DNS, or configuration of the static AC IP addresses.

3.3.2 Joining an AC by an AP

The AP selects an optimum AC from one or more ACs, joins the AC, and sets up a CAPWAP tunnel with the AC.

Working Principle

The AP sends a Discovery Request message to ACs. ACs that receive the Discovery Request message return a Discovery Response message to the AP. Among the ACs that send the response message, the AP selects an optimum AC, and sets up a DTLS connection with this AC. After the DTLS connection is successfully set up, the AP sends a Join Request message. The

AC returns a Join Response message to confirm that the AP is added to the management scope of the AC, and starts to provide services for this AP.

3.3.3 Upgrading APs

After a CAPWAP tunnel is set up between an AC and each AP, the AC upgrades APs in a large scale.

Working Principle

After an AP joins an AC, if the AP firmware version expires, the AP enters the firmware upgrade process. The AP downloads the latest firmware version from the AC, restarts after the successful upgrade, and reinitiates an AC discovery process. If the AP firmware is of the latest version, the AP downloads configuration parameters from the AC and starts running. Figure 3-2 shows the working principle.

Figure 3-2

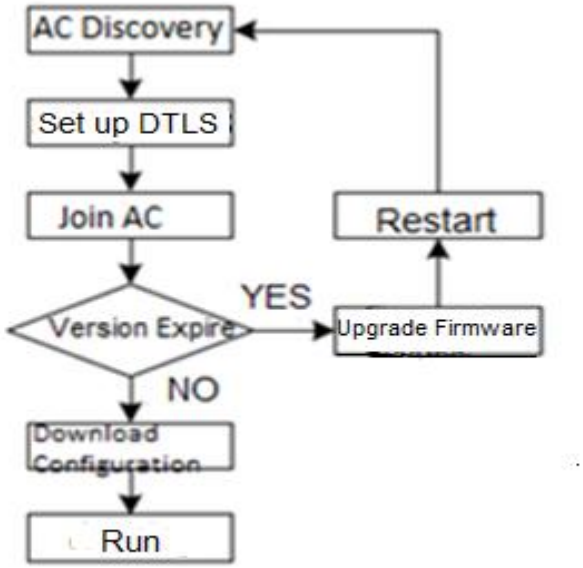


Figure 3-3 shows the typical upgrade scenario where the bandwidth is limited.

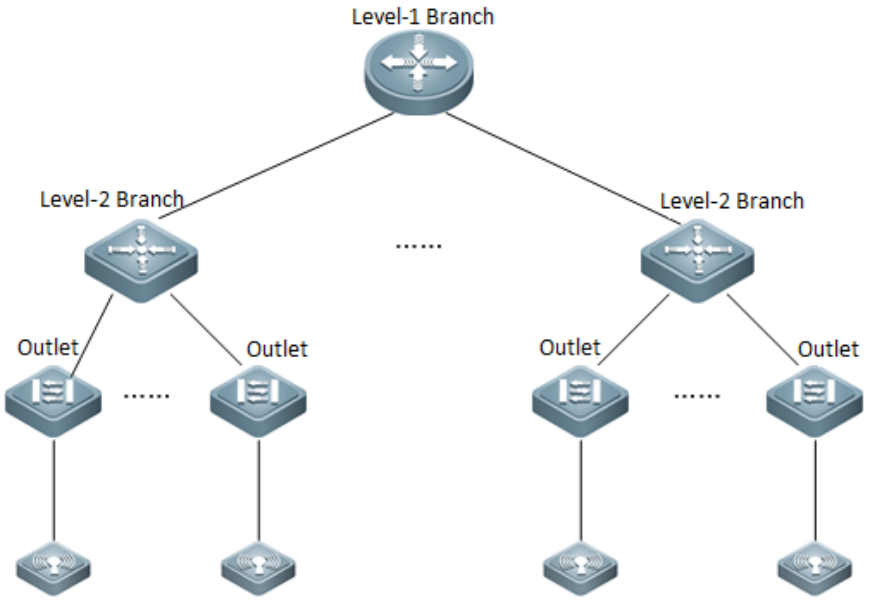
Figure 3-3



The following explains the configuration method for upgrading APs in a bank. Assume that the bank consists of one level-1 branch and multiple level-2 branches, and each branch has hundreds of outlets. One AP is deployed in one outlet, and the AC is deployed in the level-1 branch. The bandwidth between the level-1 bank and the level-2 bank is 20 Mbps, and the bandwidth between the level-2 bank and the outlet is 2 Mbps. To prevent affecting normal service provisioning of the bank, the bandwidth occupied by the AP upgrade process cannot exceed 50% of the total available bandwidth. Assume that there are eight level-2 branches, eight upgrade groups are configured on the AC, and APs of outlets under each level-2 branches are added to the corresponding upgrade group. For each AP, the maximum available bandwidth is 1 Mbps. Therefore, a bandwidth of 128 Kbps (1MByte = 128KByte) should be configured for each AP. Under each level-2 branch, the number of APs that can be upgraded concurrently is 10 (10 Mbps/1 Mbps). In addition, it is recommended that the maximum number of APs that can be concurrently upgraded by an AC be set to the number of upgrade groups multiplied by the number of APs that can be upgraded concurrently in a upgrade group, that is, 80.

3.3.4 Forwarding Data on the Tunnel

After a CAPWAP tunnel is set up between an AC and each AP, data packets can be exchanged over the data channel.

Working Principle

The CAPWAP sets up a control channel and a data channel between APs and ACs. The control channel is used by ACs to configure APs, or by APs to send event notifications to ACs, and must be encrypted. The data channel is used to exchange the 802.11 or 802.3 frames between APs and ACs. When running on the IPv4 protocol stack, the CAPWAP uses the UDP for data transmission. When running on the IPv6 protocol stack, the CAPWAP uses the UDP over the control channel, and UDP or UDP-lite over the data channel for data transmission.

3.4 Configuration

Configuration	Description and Command	
Configuring the AC Location	(Optional) It is used to configure the location information of an AC.	
	location	Configures the location information of an AC so that the physical location of the AC can be viewed.
Configuring the version number	(Optional) It is used to configure the version number.	
	set-version	Configures the version number,
Configuring the AP Location	(Optional) It is used to configure the location information of an AP.	
	location	Configures the location information of an AP so that the physical location of the AP can be viewed.
Configuring AP Time Synchronization	(Optional) It is used to enable the AP to synchronize the time with the AC.	
	timestamp	Enables the AP to synchronize the time with the AC.
Configuring Data to Allow an AP to Join an AC	(Optional) It is used to configure an AP on the AC to set up a CAPWAP tunnel.	
	ac-domain-name	Configures the DNS domain name of the AP, which is used to obtain the AC address.
	acip ipv4	Configures the static IP address of the AC accessed by the AP.
	acip ipv6	Configures the static IPv6 address of the AC accessed by the AP.
	ip address	Configures the static IP address, subnet mask, and gateway.
	ipv6 address	Configures the static IPv6 address and gateway.
	ipv6 enable	Enables the CAPWAP IPv6 function on the AP.
Configuring the ERPS ring	(Optional) It is used to configure the ERPS ring.	
	ap-cfg erps raps-vlan	Configures the EPRS ring.
Configuring an AP via an AC	(Optional) It is used to configure an AP via an AC.	
	exec-cmd	Executes ap-config commands on an AP/AP group via an AC.
Configuring a Fit AP	(Optional) It is used to perform pre-configuration on an AP to set up a CAPWAP tunnel.	
	acip ipv4	Configures the static IP address of the AC accessed by the AP.

	acip ipv6	Configures the static IPv6 address of the AC accessed by the AP.
	apip	Configures the static IP address, subnet mask, and gateway.
	apip ipv6 address	Configures the static IPv6 address and gateway.
	apip ipv6 address autoconfig default	Enables the AP to use the IPv6 stateless address autoconfiguration and generates a default route.
	apip ipv6 enable	Enables the IPv6 function of the AP.
	apip pppoe	Enables the AP to use the PPPoE dial-up mode to obtain the address.
Configuring AP Upgrade	(Optional) It is used to configure the AP upgrade data.	
	ap-serial	Creates the name of an AP product series, and specifies the AP product models that belong to this series.
	ap-image	In AP configuration mode, configures the specified AP upgrade version. In AC configuration mode, configures the specified AP software version that should be used by a specified AP product series for the upgrade, or sets the adaptive upgrade mode.
	active-bin-file	Activates the AP software version file.
	capwap upgrade max-concurrent	Configures the maximum number of APs that can be concurrently upgraded by the AC.
	capwap upgrade group	In AC configuration mode, creates a bandwidth control upgrade group.
	ap-upgrade band-width	In AC configuration mode, configures the bandwidth for centralized AP upgrade.
	ap-upgrade group	In AC configuration mode, adds APs to the bandwidth control upgrade group.
Configuring the CAPWAP Control Address	(Optional) It is used to configure the control IP address of the CAPWAP tunnel. When this address is not configured, the address of the loopback interface is used as the control IP address by default.	
	capwap ctrl-ip	Configures the control IP address of the CAPWAP tunnel.
Configuring CAPWAP Fragmentation	(Optional) It is used to configure CAPWAP fragmentation.	
	capwap mtu	Configures the maximum transmission unit (MTU) on the tunnel of a specified AP.
	capwap fragment enable	Enables CAPWAP fragmentation for a specified AP.

Configuring CAPWAP Encryption	(Optional) It is used to configure CAPWAP encryption.	
	capwap dtls enable	Enables encryption on the CAPWAP control channel.
Configuring CAPWAP Access Control	(Optional) It is used to control the maximum number of APs that can concurrently go online.	
	capwap max-concurrent	Configures the maximum number of APs that can concurrently go online.
Configuring the Echo Interval of the CAPWAP Tunnel	(Optional) It is used to configure the echo interval of the CAPWAP tunnel.	
	echo-interval	Configures the echo interval of the CAPWAP tunnel.
Configuring the Maximum Retransmission Times of a CAPWAP Packet	(Optional) It is used to configure the maximum transmission times of a CAPWAP packet.	
	capwap max-retransmit	Configures the maximum transmission times of a CAPWAP packet.

3.4.1 Configuring the AC Location

Configuration Effect

- Configure the location information of an AC so that users can conveniently check the locations of ACs on the WLAN.

Notes

- The location information is a string of 1 to 255 characters, and cannot contain any space.

Configuration Steps

- (Optional) Configure the AC location so that users can conveniently check the locations of ACs when a large number of ACs exist on the network.
- Enter the AC configuration mode, and run the **location** command to configure the AC location on the AC.
- Use the **no** form of this command to restore the default setting.

Command	**location** *location-string*
Parameter Description	*location-string*: indicates the location of an AC. The location is a string of 1 to 255 characters, and cannot contain any space.
Defaults	Ruijie_COM
Command Mode	AC configuration mode
Usage Guide	The AC location information is Ruijie_COM by default. You can configure the location information for each AC according to actual requirements so that you can conveniently check the AC location on the WLAN.

Verification

- Run the **show ac-config** command to display the AC location information and accordingly determine whether the configuration is successful.

Configuration Example

Configuring the AC Location Information as "computer-layer2"

Configuration Steps	• Enter the AC configuration mode. • Configure the AC location information.
AC	`Ruijie(config)#ac-controller` `Ruijie(config-ac)# locationcomputer-layer2`
	• Use the **no** form of this command to restore the default AC location information.
AC	`Ruijie(config)#ac-controller` `Ruijie(config-ac)#no location`
Verification	Run the **show ac-config** command to display the current location of the AC.
AC	`Ruijie#show ac-config` `ac location :Ac_COM`

Common Errors

- N/A

3.4.2 Configuring the Version Number

Configuration Effect

- Customize the firmware version.

Notes

- The customized version number contains a maximum of 63 characters.

Configuration Steps

- Optional.
- Run this command to configure the customized firmware version number.
- Use the **no** form of this command to restore the default settings.

Command	**set-version** *string*

Parameter Description	*string*: indicates the customized version number.
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	This command is used to configure the firmware version number of the AC and push the firmware version number to APs.

Verification

- Run the **show version** command to display the version number.

Configuration Example

Configuring the Customized Firmware Version Number to RGOS 10.4(2B17)-SP2

Configuration Steps	Enter the AC configuration mode. Configure the customized version number.
AC	`Ruijie(config)#ac-controller` `Ruijie(config-ac)# set-version RGOS 10.4(2B17)-SP2`
Verification	Run the **show version** command to display the version number.
AC	`Ruijie#show version` `System software version : RGOS 10.4(2B17)-SP2`

Common Errors

N/A

3.4.3 Configuring the AP Location

Configuration Effect

- Configure the location information of an AP.

Notes

- The AP location information is a string of 1 to 255 characters, and cannot contain any space.

Configuration Steps

Configuring the AP Location Information

- Optional.

- Run the **location** command to configure the AP location information.
- You can enter the AP configuration mode and configure the AP location information on the AC so that you can conveniently learn the physical location of the AP.

Command	**location***location-string*
Parameter Description	*location-string*: indicates the location of an AP. The location is a string of 1 to 255 characters, and cannot contain any space
Defaults	Null
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Run the **show ap-config running** command to display the AP location information.

Configuration Example

Configuring the Location Information of AP0001 as "AP-company"

Configuration Steps	• Enter the AP configuration mode on the AC. • Configure the location information of AP0001 as "AP-company".
AC	`Ruijie(config)# ap-config AP0001` `Ruijie(config-ap)# location AP-company`
Verification	• Run the **show ap-config running** command to display the location information of AP0001.
AC	`Ruijie#show ap-config running` `!` `ap-config AP0001` `location AP-company` `!`

Common Errors

- N/A

3.4.4 Configuring AP Time Synchronization

Configuration Effect

- Enable a specified AP or all APs in an AP group to synchronize the time with the AC.

Notes

- N/A

Configuration Steps

Enabling a Specified AP or All APs in an AP Group to Synchronize the Time with the AC

- Optional.
- To synchronize the time on the AP with that on AC, enter the AP or AP group configuration mode on the AC and run the **timestamp** command.

Command	timestamp
Parameter Description	N/A
Defaults	N/A
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Verification

- Check whether the time on the AC is the same as that on the AP.

Configuration Example

Enabling AP0001 to Synchronize the Time with the AC

Configuration Steps	• Enter the AP configuration mode on the AC. • Enable AP0001 to synchronize the time with the AC.
AC	`Ruijie(config)# ap-config AP0001` `Ruijie(config-ap)# timestamp`
Verification	• Run the **show clock** command to display the time on the AP0001 and the AC.
AC	`Ruijie#showclock` `16:41:05 UTC Thu, Oct 17, 2013`

Common Errors

- N/A

3.4.5 Configuring Data to Allow an AP to Join an AC

Configuration Effect

- Configure the static IP addresses of ACs. The AP will send the Discover Request messages to these static IP addresses to check the effectiveness of ACs, and then select and joint an AC to set up a CAPWAP tunnel.

Notes

- A fit AP is generally not configured. It can discover ACs by means of broadcast, unicast, DHCP, or DNS, or join ACs based on the statically configured AC addresses.
- If the AP address is configured as the static address, the DHCP/DHCPv6 function will be disabled. In this case, the AC address cannot be obtained from the DHCP/DHCPv6 option. Therefore, before this command is configured, you need to configure the address of the connected AC in AP configuration mode so that the AP can discover and join the AC when the AP and the AC are not in the same subnet.
- If the current address of the AP is different from the address specified in the AC command, the AP static address will be updated and the CAPWAP tunnel will be re-established. If IPv6 is not enabled on the AP, the CAPWAP tunnel will not be re-established.
- If both the IPv4 and IPv6 addresses of the AP are specified in the configuration, and IPv6 is enabled on the AP, the AP will discover the IPv4 and IPv6 ACs simultaneously.

Configuration Steps

Configuring the Static AC Address

- Optional.
- The AC address can be obtained through DHCP or DNS. Alternatively, the static AC address can be configured in AP configuration mode on the AC or configured on the AP.
- When the AC address is obtained in static mode, run the **acip ipv4** or **acip ipv6** command to configure the static AC address.

Command	**acip ipv4***ip-address*[*ip-address*…]
Parameter Description	*ip-address*: indicates the static IP address. At most six static addresses can be configured.
Defaults	No static AC IP address is configured by default.
Command Mode	Global configuration mode on the AP or AP configuration mode on the AC
Usage Guide	N/A

Command	**acip ipv6** *ipv6-address*[*ipv6-address*…]
Parameter Description	*ipv6-address*: indicates the static IP address. At most six static addresses can be configured.
Defaults	N/A
Command Mode	Global configuration mode on the AP or AP configuration mode on the AC
Usage Guide	N/A

Configuring the Domain Name Used by the AP to Discover the AC

- (Optional) Run the **ac-domain-name** command to configure the DNS domain name on the AC so that the AP can discover the AC based on the DNS domain name.
- When the AC address is obtained in dynamic mode, configure the DNS domain name on the AC. The AC address can be obtained based on the DNS domain name.
- Generally, if the DNS domain name is not configured, the AP cannot obtain the IP address of the AC through the DNS.

Command	**ac-domain-name***ac-domain-name*
Parameter Description	*ac-domain-name*: indicates the AC domain name.
Defaults	ac.ruijie.com.cn
Command Mode	AP configuration mode or AP group configuration mode on the AC
Usage Guide	N/A

Configuring the Static IP Address of the AP

- Optional.
- On the AP, configure the static IPv4 or IPv6 address of the AP so that the AP can use the fixed IPv4 or IPv6 address to access the AC.

Command	**ip address** *ip-address network-mask gateway*
Parameter Description	*ip-address*: indicates the IP address of the AP. *network-mask*: indicates the subnet mask of the AP. *gateway*: indicates the gateway of the AP.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	An AP can obtain its own IP address through the static configuration or DHCP. If the static IP address is not configured on the AP, the AP obtains the address through DHCP and joins the AC. In this case, you can run this command to configure the static IP address of the AP so that the address can remain unchanged after the AP is restarted.

Configuring the Static IPv6 Address of a Specific AP

- Optional.

Command	**ipv6 address** *ipv6-address-with-mask gateway*
Parameter Description	*ipv6-address-with-mask*: indicates the IPv6 address of the AP. The format is X:X:X:X::X/24. *gateway*: indicates the IPv6 gateway of the AP.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	When IPv6 is enabled, the AP can obtain its own IPv6 address through the static configuration or DHCPv6. If the static IPv6 address is not configured on the AP, the AP obtains the address through DHCPv6 and

	joins the AC. In this case, you can run this command to configure the static IPv6 address of the AP so that the address can remain unchanged after the AP is restarted.

Enabling the AP to Support IPv6 Access

- Optional.
- Run this command to control whether an AP sets up a CAPWAP IPv6 tunnel.
- If a CAPWAP IPv6 tunnel needs to be set up, run the **ipv6 enable** command in AP configuration mode on the AC to support establishment of the IPv6 tunnel.

Command	**ipv6 enable**
Parameter Description	N/A
Defaults	IPv6 is disabled on the AP by default.
Command Mode	AP configuration mode
Usage Guide	If the IPv6 enable/disable status of the AP changes due to configuration of this command, the AP re-establishes the CAPWAP tunnel. When IPv6 is enabled on the AP, and the AP is configured with both static IPv4 and IPv6 addresses, the AP attempts to discover the IPv4 and IPv6 ACs simultaneously during re-establishment of the CAPWAP tunnel. For discovered ACs, the AP does not necessarily select and join an IPv6 AC. To ensure that the AP selects and joins an IPv6 AC, delete the IPv4 static address of the AP and retain only the static IPv6 address of the AP before IPv6 is enabled on the AP.

Verification

- Run the **show ap-config running** command to check whether the configuration is successful.

Configuration Example

Enabling the AP to Obtain the IP Address of the AC Based on the Static IPv4 Address of the AP

Configuration Steps	● Enter the AP configuration mode on the AC. ● Set the static IP address of the AC accessed by the AP to 192.168.1.1. ● Set the static IP address of the AP to 1.1.1.1, subnet mask to 255.255.255.0, and gateway to 1.1.1.2.
AC	`Ruijie(config)# ap-config AP0001` `Ruijie(config-ap)# acip ipv4 192.168.1.1` `Ruijie(config-ap)# ip address 1.1.1.1 255.255.255.0 1.1.1.2`
Verification	● Check the AP configurations.
AC	`Ruijie#show ap-config running` `!` `ap-config AP0001`

Configuration Steps	● Enter the AP configuration mode on the AC. ● Set the static IP address of the AC accessed by the AP to 192.168.1.1. ● Set the static IP address of the AP to 1.1.1.1, subnet mask to 255.255.255.0, and gateway to 1.1.1.2.
AC	`Ruijie(config)# ap-config AP0001` `Ruijie(config-ap)# acip ipv4 192.168.1.1` `Ruijie(config-ap)# ip address 1.1.1.1 255.255.255.0 1.1.1.2`
Verification	● Check the AP configurations.
	`acip ipv4 192.168.1.1` `ip address 1.1.1.1 255.255.255.0 1.1.1.2` `!`

Enabling the AP to Obtain the IP Address of the AC based on the DNS Domain Name

Configuration Steps	● Enter the AP configuration mode on the AC. ● Set the DNS domain name of the AC to ruijie-ac.
AC	`Ruijie(config)# ap-config AP0001` `Ruijie(config-ap)# ac-domain-name ruijie-ac`
Verification	● Check the AP configurations.
AC	`Ruijie#show ap-config running` `!` `ap-config AP0001` ` ac-domain-name ruijie.ac` `!`

Enabling IPv6 on the AP

Configuration Steps	● Enter the AP configuration mode on the AC. ● Enable IPv6 on the AP.
AC	`Ruijie(config)# ap-config AP0001` `Ruijie(config-ap)# ipv6 enable`
Verification	● Check the AP configurations.
AC	`Ruijie#show ap-config running` `!` `ap-config AP0001`

Configuration Steps	● Enter the AP configuration mode on the AC. ● Enable IPv6 on the AP.
AC	`Ruijie(config)# ap-config AP0001` `Ruijie(config-ap)# ipv6 enable`
Verification	● Check the AP configurations.
	`ipv6 enable` `!`

Common Errors

- N/A

3.4.6 Configuring the ERPS Function on the AP

Configuration Effect

- The i-Share+ master AP requires the Ethernet Ring Protection Switching (ERPS) function. The fit AP does not save any configuration and therefore, the ERPS command needs to be saved.

Notes

- A link needs to be disconnected or a port needs to be shut down during network planning. The ring topology can be built only after the ERPS link is configured.
- Configure a Ring Protection Link (RPL) link on a device in the ERPS ring, so that traffic is balanced to dual upstream links. When one link fails or one device is faulty, the blocked RPL link is connected to prevent link failure.
- The VLAN used by the ERPS will occupy the VLAN capacity of the device. Therefore, the VLAN cannot be set to VLAN 1 or VLAN 2444, both of which are default VLANs. It cannot be the same with the VLAN of an STA specified by the **Interface-mapping** command or the VLAN of a wired port specified by the **wired-VLAN** command. It cannot be the same with the VLAN specified by the **ap-vlan** command, neither.

Configuration Steps

↘ Configuring an ERPS Single Ring

- Optional.
- Only the i-Share+ master AP supports this command.

Command	**ap-cfg erps raps-vlan** *vlan-id* **ring-port west** *interface-name1* **east** *interface-name2*
Parameter Description	*vlan-id*: indicates the R-APS VLAN ID. *interface-name1*: indicates the name of the west port. interface-name2: indicates the name of the east port.

Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	N/A

Command	**ap-cfg erps raps-vlan** *vlan-id* **rpl-port** { **west** | **east** } **rpl-owner**
Parameter Description	*vlan-id*: indicates the R-APS VLAN ID. **West**: specifies the west port to be the RPL owner. **east**: specifies the east port to be the RPL owner.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Run the **show erps** command to display the ERPS configuration.

Configuration Example

Configuring the ERPS Function on the AM5528

Configuration Steps	● Enter the AP configuration mode of the AC. ● Configure an ERPS single ring. ● Configure the RPL port.
AP	`Ruijie(config)#ap-cfg erps raps-vlan 10 ring-port west gigabitEthernet 0/26 east gigabitEthernet 0/25` `Ruijie(config)#ap-cfg erps raps-vlan 10 rpl-port east rpl-ower`
Verification	● Run the **show erps** command to display the ERPS configuration.
AP	`Ruijie(config)#show erps` `ERPS Information` `Global Status : Enabled` `Link monitored by : Not Oam` `----------` `R-APS VLAN : 10` `Ring Status : Enabled` `West Port : Gi0/26 (Link Failure)` `East Port : Gi0/25 (Forwarding)` `RPL Port : East Port` `Protected VLANs : ALL` `RPL Owner : Enabled` `Holdoff Time : 0 milliseconds` `Guard Time : 500 milliseconds` `WTR Time : 2 minutes` `Current Ring State : protection` `Associate R-APS VLAN :` `Ruijie(config)#`

Common Errors

- N/A

3.4.7 Configuring an AP to Execute a Command

Configuration Effect

- (Optional) On the AC, configure an AP to execute a command.
- (Optional) On the AC, configure all APs in an AP group to execute a command.

Notes

- N/A

Configuration Steps

Configuring an AP to Execute a Command

- (Optional) Enter the AP configuration mode.
- On the AC, configure the AP to execute a command.

Command	**exec-cmd mode** *exec-mode* **cmd** *exec-cmd* [**slot** { *id* | **all** } | **once**]
Parameter Description	*exec-mode*: indicates the mode in which a command is executed on the AP. *exec-cmd*: indicates the command to be executed on the AP. *id* : Indicates the slot ID of MAPs of i-Share+ AP. **all**: Indicates all MAPs of i-Share+ AP.**once**: indicates that the command is executed only once and is not saved.
Defaults	N/A
Command Mode	Single AP configuration mode/All APs configuration mode
Usage Guide	Some configuration commands are supported currently only by the AP and they are unavailable on the AC. To configure the commands for APs on the AC, run the **exec-cmd** command. To cancel or change the configuration of the **exec-cmd** command, run the **no exec-cmd** command to remove the configuration and then run the **exec-cmd** command to cancel or change the required configuration. Expanding the **exec-cmd** command delivers the command to MAP and run the command on the MAP. If **ap-config all** and **ap-config** are configured simultaneously, for online APs, the later configuration will take effect; for offline APs, **ap-config** has a higher priority than **ap-config all**. If the AC is already configured with a command for configuration delivery, please do not use this command again. Otherwise, the configuration may conflict. Note: If a dedicated command is used on an AC to deliver configurations to an AP, do not use this command to deliver the configurations. Otherwise, conflicts occur.

Verification

- Log in to the AP to check whether the configuration takes effect. On the AC, run the **show run** or **show ap-config run** command to check whether the configuration takes effect.

Configuring APs in an AP Group to Execute a Command

- (Optional) Enter the AP group configuration mode.
- Configure all APs in an AP group to execute a command.

Command	**exec-cmd** *exec-cmd*
Parameter Description	*exec-cmd*: indicates the command to be executed on all APs in an AP group.
Defaults	N/A
Command Mode	AP group configuration mode.
Usage Guide	Some configuration commands are available only in AP configuration mode and they are unavailable in AP group configuration mode. To configure such a command for all APs in an AP group, run the **exec-cmd** command in the AP group. Note that the configuration is not saved in AP group configuration mode, that is, the command is executed only once on all APs in the current AP group. If the configuration already exists in AP configuration mode, the original configuration will be overridden when the command is executed in AP group configuration mode. Note: If a dedicated command is used on an AC to deliver configurations to an AP, do not use this command to deliver the configurations. Otherwise, conflicts occur.

Verification

- Run the **show ap-config run** command to check whether the configuration of the APs in an AP group takes effect.

Configuration Example

Disabling the Eweb Function for an AP on the AC and Configuring Bluetooth iBeacon for all APs in an AP Group

Configuration Steps	● On the AC, disable the Eweb function for APs. ● On the AC, enable the Eweb function for APs. ● Enable Bluetooth iBeacon for all APs in an AP group. ● Disable the Eweb function for all APs in the AP group.
AC	`Ruijie(config)#ap-config AP1` `Ruijie(config-ap)# exec-cmd mode configure cmd "no enable service web-server all"` `Ruijie(config-ap)# no exec-cmd mode configure cmd "no enable service web-server all"` `Ruijie(config-ap)# exec-cmd mode configure cmd "enable service web-server all"` `Ruijie(config)#ap-group default` `Ruijie(config-group)#exec-cmd ibeacon uuid ffffffffffffffffffffffffffffffff major ffff minor ffff` `Ruijie(config-group)#exec-cmd exec-cmd mode configure cmd "no enable service web-server all"`
Verification	● On the AC, check whether the configuration takes effect.
AC	`Ruijie#show ap-config running` `ap-config AP1` `exec-cmd mode configure cmd "no enable service web-server all"` `ibeacon uuid ffffffffffffffffffffffffffffffff major ffff minor ffff`

Common Errors

The **exec-cmd** command needs to be changed, but the **no exec-cmd** command is not executed to delete original configuration, or the **exec-cmd** command is not re-executed to cancel the configuration.

3.4.8 Configuring a Fit AP

Configuration Effect

- Configure the static IP address, subnet mask, next hop, and AC address on a fit AP so that the AP can use the static address to communicate with the AC.

Notes

- If the AP address is configured as the static address, the DHCP function will be disabled. In this case, the AC address cannot be obtained from the DHCP/DHCPv6 option. Therefore, you need to configure the address of the connected AC on the fit AP so that the AP can discover and join the AC when the AP and the AC are not in the same subnet.
- The fit AP configuration commands have the same functions as some AP configuration commands used on the AC. When the two configurations conflict with each other, the AP may be re-connected to the AC only based on the configurations on the AC.
- The fit AP configuration commands are automatically saved.

Configuration Steps

Configuring the Static IP Address of the AP

- Optional.
- When IP addresses of APs must be statically planned at the early stage of deployment, you can configure IP addresses on the APs.
- Configure the static IPv4 or IPv6 address of the AP so that the AP can use the IPv4 or IPv6 address to access the AC.
- Run the **apip ipv4** command to configure the static IPv4 address of the AP.
- Run the **apip ipv6** command to configure the static IPv6 address of the AP.

Command	**apip ipv4** *ip-addressnetwork-mask gateway*
Parameter Description	*ip-address*: indicates the static IP address. *network-mask*: indicates the subnet mask. *gateway*: indicates the gateway address.
Defaults	N/A
Command Mode	Global configuration mode on the AP
Usage Guide	N/A

Command	**apip ipv6** *ipv6-address-with-mask gateway*
Parameter Description	*ipv6-address-with-mask*: indicates the IPv6 address containing the mask length. The format is X:X:X:X::X/24. *gateway*: indicates the IPv6 gateway address.
Defaults	N/A
Command Mode	Global configuration mode on the AP
Usage Guide	N/A

Configuring the Static IP Address of the AC Accessed by the AP

- Optional.

- When the AP is configured to use the static IP address, you must also specify the IP address of the accessed AC on the AP.
- The static address type of the AC accessed by the AP must be the same as that of the AP. Ensure that both the AC and the AP use the IPv4 static address, or both use the IPv6 static address.
- Run the **acip ipv4** command so that the AP joins a specified IPv4 AC.
- Run the **acip ipv6** command so that the AP joins a specified IPv6 AC.

Command	**acipipv4** *ip-address*[*ip-address*…]
Parameter Description	*ip-address*: indicates the static IP address. At most six static addresses can be configured.
Defaults	N/A
Command Mode	Global configuration mode on the AP or AP configuration mode on the AC
Usage Guide	N/A

Command	**acipipv6** ipv6-address [*ipv6-address*…]
Parameter Description	*ipv6-address*: indicates the IPv6 address of the connected AC. At most six static addresses can be configured.
Defaults	N/A
Command Mode	Global configuration mode on the AP or AP configuration mode on the AC
Usage Guide	N/A

Enabling the AP to Use the Stateless Address

- Optional.
- On the AP, configure data so that the AP uses the IPv6 stateless address autoconfiguration and a default route is generated.
- Run the **apip ipv6 enable** command to enable the IPv6 function of the AP.

Command	**apip ipv6 address autoconfig default**
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode on the AP
Usage Guide	After this command is executed, the AP uses the IPv6 stateless address autoconfiguration, and a default route is generated.

Command	**apip ipv6 enable**

Parameter Description	N/A
Defaults	The IPv6 function of the AP is enabled by default.
Command Mode	Global configuration mode on the AP
Usage Guide	You can run this command to enable or disable the CAPWAP IPv6 discovery function only on an IPv4 network.

Configuring the CAPWAP IPv6 Discovery Function on the AP

- Optional.
- You can disable the CAPWAP IPv6 discovery function only on an IPv4 network to prevent the attempts made by CAPWAP to set up an IPv6 tunnel, thus reducing the CAPWAP packets on the network.
- Run the **no apip ipv6 enable** command to disable the IPv6 function of the AP.

Command	**apip ipv6 enable**
Parameter Description	N/A
Defaults	The IPv6 function of the AP is enabled by default.
Command Mode	Global configuration mode on the AP
Usage Guide	You can run this command to enable or disable the CAPWAP IPv6 discovery function only on an IPv4 network.

Enabling the AP to Use the PPPoE Dial-up Mode to obtain the Address

- Optional.
- When the AP needs to connect to a remote Internet service provider (ISP) through the ADSL and obtains the network access capability, run this command so that the AP can use the PPPoE dial-up mode to obtain the address.

Command	**apip pppoe**
Parameter Description	N/A
Defaults	By default, the PPPoE mode is not specified and the AP obtains the address through DHCP.
Command Mode	Global configuration mode on the AP
Usage Guide	The command configures only the mode (PPPoE dial-up mode) selected by the AP to obtain the address. After this command is configured, you need to add the PPPoE configurations and let the default route to point to the dialer interface so that the AP can communicate with the AC. CAPWAP can only select dialer 1 as the source interface. Therefore, when configuring the PPPoE dial-up mode, dialer 1 must be used.

Verification

- Check whether the fit AP configuration commands exist.
- Check whether the AP can communicate with the AC.

Configuration Example

Configuring the Static IP Address of the AC Accessed by the AP

Configuration Steps	● Configure the static IPv4 address of the AP. ● Configure the static IPv4 address of the AC accessed by the AP.
AP	`Ruijie(config)# apip 192.168.1.2 255.255.255.0 192.168.1.1` `Ruijie(config)# acip ipv4 1.1.1.1`
Verification	● Run the **show running-config** command to display the configurations.
AP	`!` `apip 192.168.1.2 255.255.255.0 192.168.1.1` `acip ipv4 1.1.1.1` `!`

Enabling the AP to Use the PPPoE Dial-up Mode to Obtain the Address

Configuration Steps	● Enable the AP to select the PPPoE dial-up mode to obtain the address. ● Configure the PPPoE. ● Configure the default route. ● Configure the static IPv4 address of the AC accessed by the AP.
AP	`Ruijie(config)# apip pppoe` `Ruijie(config)# interface FastEthernet 0/1` `Ruijie(config-if-FastEthernet 0/1)#pppoe enable` `Ruijie(config-if-FastEthernet 0/1)#pppoe-client dial-pool-number 1 no-ddr` `Ruijie(config-if-FastEthernet 0/1)#exit` `Ruijie(config)# interfacedialer 1` `Ruijie(config-if-Dialer1)#ip address negotiate` `Ruijie(config-if-Dialer1)#ppp chap hostname ruijie` `Ruijie(config-if-Dialer1)#ppp chap password ruijie` `Ruijie(config-if-Dialer1)#ppp pap sent-username ruijie password ruijie` `Ruijie(config-if-Dialer1)#dialer pool 1` `Ruijie(config-if-Dialer1)#exit` `Ruijie(config)#ip route 0.0.0.0 0.0.0.0 dialer 1` `Ruijie(config)# acip ipv4 1.1.1.1`
Verification	● Run the **show running-config** command to display the configurations.
AP	`!` `apip 192.168.1.2 255.255.255.0 192.168.1.1` `acip ipv4 1.1.1.1` `!`

Common Errors

- N/A

3.4.9 Configuring AP Upgrade

Configuration Effect

- Upgrade the AP software version through configuration on the AC.

Notes

- Configure the data to activate the AP software version file. This command loads the **.bin** file to the memory only when the AP needs to be upgraded. When no AP needs to be upgraded, the bin file will be automatically removed from the memory.

- During the adaptive upgrade, the transitional version between rgos10 and rgos11 cannot be used to upgrade an AP using the rgos10 system.
- When the bandwidth is limited, use the bandwidth control function for the upgrade.

Configuration Steps

Creating the AP Product Series

- (Optional) Run the **ap-serial** command to configure an AP product series on the AC.
- To upgrade the AP software version through the AC, you must configure the AP hardware version and product models for a specified product series on the AC.
- An AP software version is applicable to a series of AP products. You can configure the AP hardware version and product models for a specified product series, and use the software version to upgrade specified AP models.

Command	**ap-serial***serial-name ap-pid1 ap-pid2 ... ap-pidn* [**hw-ver** *hardware-version*]
Parameter Description	*serial-name*: indicates the name of the AP series to be created. *ap-pid1 ap-pid2 ... ap-pidn*: lists the product models to be added to the AP series. *hardware-version*: specifies the AP hardware version.
Defaults	No AP series is configured by default.
Command Mode	AC configuration mode
Usage Guide	N/A

Activating the AP Software Version File

- (Optional) Run the **active-bin-file** command to activate an AP software version on the AC.
- To upgrade the AP software version through the AC, you must activate the AP software version on the AC.
- Only an activated AP software version can be used for the upgrade.

Command	**active-bin-file** *filename*[**rgos10**]
Parameter Description	*filename*: specifies the name of a software version. The name may contain a path prefix (**flash:**,**tmp:**, or**usb0:**), followed by a real file name. The maximum length of a file name is 64 bytes. **rgos10:** indicates that a transitional version between 10.X and 11.X is activated. It is applicable only to the AP software version.
Defaults	The AP software version is not activated by default.
Command Mode	AC configuration mode
Usage Guide	1. To download a software version from the AC to upgrade an AP, you must first activate the version file. The rgos10 system differs a lot from the rgos11 system. Therefore, when using a transitional version between rgos10 and rgos11 for the upgrade, you must add the rgos10 keyword. 2. The **.bin** file is loaded to the memory only when an AP needs to be upgraded. When no AP needs to be upgraded, the bin file will be automatically removed from the memory.

	3. Before configuring this command, ensure that the software version file already exists in the AC system files.

Upgrading the Version of Specified APs

- Optional: Run the **ap-image** command to use a specified file to upgrade a specified AP series on the AC. This command takes effect on all APs connected to the AC.
- To upgrade the AP software version through the AC, you must first specify the upgrade file used by the AP.
- To upgrade a specified AP series, you must activate the AP software version, specify the AP series, and specify a file for upgrading the specified AP series.

Command	**ap-image** *filename*
Parameter Description	*filename*: specifies the software version name.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring Adaptive Upgrade

- (Optional) Run the **ap-image auto-upgrade** command so that the AC can automatically identify applicable AP products based on the AP upgrade file and upgrade all applicable APs.
- The command automatically matches the AP models to which the software version is applicable and upgrades these APs.

Command	**ap-image**{ **auto-upgrade** | *filename serial-name*}
Parameter Description	**auto-upgrade:** indicates that the product model is automatically matched for the upgrade. *filename*: specifies the software version name. This file name must be the same as that specified by the **active-bin-file** command. *serial-name*: indicates the name of the AP series to be upgraded.
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	You can use the **auto-upgrade** option to automatically match the software version and upgrade APs without configuring the mapping relationship between the AP product models and software version. You can also use a specified file to upgrade a specified AP product series. When both the automatic upgrade mode and the specified series upgrade mode exist, the specified series upgrade mode is used preferentially. To enable the AC to upgrade the version of a specified AP product series, you must create the AP product series, configure the software version corresponding to the specified APs, and activate the software version. The three steps are mandatory.

Configuring AP Upgrade Function in Hierarchical AC Scenarios

- Optional.

- Enable the AP upgrade function on the center AC or a branch AC in hierarchical AC scenarios.

Command	**capwap upgrade center enable**
Parameter Description	N/A
Defaults	The AP upgrade function is enabled on the center AC by default (disabled on branch ACs).
Command Mode	AC configuration mode
Usage Guide	1. This command applies only to hierarchical AC scenarios. 2. When the AP upgrade function on an AC is changed from enabled to disabled, upgrade configurations (activated bin, automatic upgrade, sequential upgrade, and single AP upgrade) on the AC are automatically cleared. 3. After a branch AC connects to the center AC, the branch AC automatically synchronizes configurations of the center AC. 4. When a branch AC is in the connected state, configurations on the branch AC cannot be modified. The configurations can only be modified on the center AC and automatically synchronized to the branch AC. When the branch AC is in the standalone state, configurations on the branch AC can be modified.

Configuring the Maximum Number of APs That Can Be Concurrently Upgraded by the AC

- Optional.
- Limit the maximum number of APs that can be concurrently upgraded by the AC.

Command	**capwapupgrade max-concurrent** *num*
Parameter Description	*num*: indicates the maximum number of APs that can be concurrently upgraded by the AC. The default value is 18. The value ranges from 1 to 200.
Defaults	15
Command Mode	AC configuration mode
Usage Guide	N/A

Creating an Upgrade Group

- Optional.
- Create an upgrade group. The AC can evenly distribute the centralized upgrade quota to the upgrade group through balanced scheduling to limit the bandwidth and avoid wasting the bandwidth.

Command	**capwap upgrade group** *group-name* [**max-concurrent***num*]
Parameter Description	*group-name*: indicates the name of an upgrade group. The upgrade group name cannot be set to "default". *num*: indicates maximum number of APs that can be concurrently upgraded in the group. The default value is 5. The value ranges from 1 to 200.
Defaults	By default, no upgrade group is configured, and the AP upgrade is not limited by the bandwidth. When configuring an upgrade group, the maximum number of APs that can be concurrently upgraded in the group is 5 by default.

Command Mode	AC configuration mode
Usage Guide	N/A

Adding APs to an Upgrade Group

- Optional.
- Add APs to an upgrade group. Limit the number of APs that are upgraded in a centralized manner in this group through scheduling and configuration to control the bandwidth by upgrade group.

Command	**ap-upgrade group** *group-name*
Parameter Description	*group-name*: indicates the name of the upgrade group. Before adding APs to an upgrade group, you must run the **capwap upgrade group** command to create the upgrade group.
Defaults	APs are not added to any upgrade group.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring the Bandwidth Used for AP Upgrade

- Optional.
- Configure the bandwidth used for AP upgrade.

Command	**ap-upgrade band-width***num*
Parameter Description	*num*: indicates the bandwidth used for AP upgrade. The unit is 1 KB. The value ranges from 8 to 1024.
Defaults	The bandwidth is not limited.
Command Mode	AP configuration mode
Usage Guide	The bandwidth-limited AP upgrade configuration commands include the command for configuring the bandwidth used for AP upgrade, the command for creating an upgrade group, and the command for adding APs to the upgrade group.

Verification

- Check whether the AP version is successfully upgraded.
- Check the upgrade status of the bandwidth control upgrade group and APs in the group.

Configuration Example

Configuring the AP Upgrade Data

Configuration Steps	● Enter the AC configuration mode on the AC. ● Create the name of an AP product series on the AC. ● Activate the specified AP software version used for the upgrade on the AC. ● Configure the AP upgrade version file on the AC.
AC	`Ruijie(config-ac)# ap-serial serial1 AP220-E AP220-SE AP620-H hw-ver 1.0` `Ruijie(config-ac)# active-bin-file ap.bin` `Ruijie(config-ac)# ap-image ap.bin serial1` `Ruijie(config-ac)# exit`
Verification	● Display the list of files activated on the AC.
AC	`Ruijie#show ac-config active-file` `Cnt File Name Version Used Cnt Ready` `------ ------------ ---------- ---------- --------` `1 ap.bin RGOS 10.4(1t7)(1T7), Release(88888) 1 1`

Configuring the AP Upgrade During Which the Bandwidth is Under Control

Configuration Steps	● Enter the AC configuration mode on the AC. ● Create an AP upgrade group on the AC. ● Exit from the AC configuration mode. ● Enter the AP configuration mode. ● Configure the specified AP upgrade group on the AC. ● Activate the bandwidth used for AP upgrade on the AC.
AC	Ruijie(config-ac)# capwap upgrade group UPGRADE-GROUP1 max-concurrent 10 Ruijie(config-ac)# exit Ruijie(config)#ap-config 8832.0000.1111 Ruijie(config-ap)# ap-upgrade group UPGRADE-GROUP1 Ruijie(config-ap)# ap-upgrade band-width 128 Ruijie(config-ap)# exit
Verification	● Display the upgrade group and APs in the group on the AC. ● Display the APs and their bandwidths in an upgrade group on the AC.
AC	Ruijie#show ac-config upgrade-group Cnt Group-Name Max-Concurrent Token cnt Upgrading cnt ------ ---------- ---------- ---------- 1 UPGRADE-GROUP1 10 2 1 Ruijie#show ac-config upgrade-groupUPGRADE-GROUP1 Group have 2 ap, online 1 offline 1 Cnt Ap-Name Ap-Mac Online Upgrade Band-width ------- ---------- ---------- ------- --------- 1 ap220e 8832.0000.1111 true true 128 2 ap330 - false false 128 Ruijie#show ap-config wtp-info 8832.0000.1111 Ruijie#show ap-config wtp-info ap220e Upgrade-banfwidth : 128 Upgrade group : UPGRADE-GROUP1

Configuring AP Upgrade Function in Hierarchical AC Scenarios

Configuration Steps	1. Enable the AP upgrade function on the center AC (and disable it on branch ACs). `Ruijie(config-ac)# capwap upgrade center enable` 2. Enable the AP upgrade function on a branch AC (and disable it on the center AC). `Ruijie(config-ac)# no capwap upgrade center enable` 3. Cancel the configurations. `Ruijie(config-ac)# default capwap upgrade center enable`
Verification	Run the **show running-config** command to check whether the configuration is successful.

Common Errors

- The AP upgrade data is configured, but the software version file used for the upgrade does not exist in the AC system files.

3.4.10 Configuring a Mini AP

Configuration Effect

- One rack-type AP can carry multiple mini APs. This operation is performed to manage and name mini APs, and display their installation status, thus facilitating the mini AP management.

Notes

- N/A

Configuration Steps

↘ Naming a Mini AP

- (Optional) Run the **slot** command to name a mini AP in a specified slot.
- This configuration takes effect only for i-Share APs. The corresponding radio frequency (RF) card can be named to determine the position of this card.

Command	**slot** *slot-id* {*slot-name* [**secondary**] | **mac** *mac-address slot-name* }
Parameter Description	*slot-id*: indicates the slot ID. The slot ID ranges from 1 to 24. *slot-name*: indicates the name of an AP card. The name is a string of 1 to 63 characters, and cannot contain any space. **secondary**: Applies to the secondary AP. *mac-address*: MAC address of the Mini AP.
Defaults	An AP card is not named by default.

Command Mode	AP configuration mode
Usage Guide	This command takes effect only for i-Share+ APs and cannot be configured for all APs. If you want to name a secondary Mini AP, please add the **secondary** parameter. Each slot can be configured with two MAC addresses.

Updating the Installation Status of Mini APs

- (Optional) Run the **install update** or **uninstall** command to update the installation status of mini APs.
- If the state of a removed mini AP is displayed as offline, you can update its installation status.

Command	**install update**
Parameter Description	N/A
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	If a mini AP is installed in a specified slot on the rack-type AP but is later manually removed, the system determines that this mini AP is offline. This command is executed to query a rack-type AP that is currently online, and the online mini APs on the rack are treated as installed mini APs. Configurations of this command are not saved.

Command	**uninstall** *slot-id* [**secondary**]
Parameter Description	*slot-id*: indicates the slot ID. The slot ID ranges from 1 to 24. **secondary**: Applies to the secondary AP.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	If a mini AP is installed in a specified slot on the rack-type AP but is later manually removed, the system determines that this mini AP is offline. You can use this command to remove a mini AP from the corresponding slot. If the mini AP in this slot is online, execution of this command is meaningless. Configurations of this command are not saved. In addition, the command cannot be used in all AP configuration mode. If you want to name a secondary Mini AP, please add the **secondary** parameter.

Restarting a Mini AP

- (Optional) Run the **reset slot** *slot-id* command to restart a mini AP in a specified slot.
- To reset a mini AP, you can use this command to power off the mini AP and then power it on again.
- This command applies to two Mini APs of a slot.

Command	**reset slot** *slot-id*
Parameter Description	*slot-id*: indicates the slot ID. The slot ID ranges from 1 to 24.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	This command takes effect only on a rack-type AP, and cannot be used in all AP configuration mode. Configurations of this command are not saved.

Verification

- Check the installation information of mini APs, including the names and online status.

Configuration Example

Naming a Mini AP

Configuration Steps	● Enter the AP configuration mode on the AC. ● Name the mini AP in a specified slot.
AC	The following example sets the name of Mini AP1 to 1#101. `Ruijie(config)# ap-config AP0001` `Ruijie(config-ap)# slot 1 Dormitory 1#101` The following example sets the name of AP0001, secondary Mini AP1 of slot 1, to 1#102. `Ruijie(config)# ap-config AP0001` `Ruijie(config-ap)# slot 1 1#102 secondary` The following example sets the name of Mini AP (MAC address: 0001.0001.0001) of slot 1 to 1#101 and the name of Mini AP (MAC address: 0001.0001.0002) of slot 1 to 1#102. `Ruijie(config)# ap-config AP0001` `Ruijie(config-ap)# slot 1 mac 0001.0001.0001 1#101` `Ruijie(config-ap)# slot 1 mac 0001.0001.0002 1#102`
Verification	● Check the name of the mini AP on the AC.
AC	`Ruijie#show ap-config summary slot` `Total Install Number: 2` `Total Online Number: 1` `Total Offline Number: 1` `AP(AP0001)'s Slots Information` `Install Number: 2` `Online Number: 1` `Offline Number: 1` `AP mac Slot ID Role Slot Name Model Slot Mac Radio Radio Up/Off time State` `-------------- ------- --------- ------------------------------ --------- -------------- - ------------------- ------------------- ----------- -------` `00d0.f822.3418 1 master Dormitory 1#101 MAP552 5869.6c36.e268 1 E 0 6* 100 2 E 0 157* 100 1:03:39:38 online` `00d0.f822.3418 2 slave Dormitory 1#102 MAP552 5869.6c36.e269 3 N 4 N 1:03:39:38 offline`

Common Errors

- N/A

3.4.11 Configuring the CAPWAP Address Control

Configuration Effect

- Configure the maximum number of APs that can concurrently go online.

Notes

- If the configured value is too small, the total online duration of all APs connected to the AC will be relatively long.

Configuration Steps

↘ Configuring the Maximum Number of APs That Can Concurrently Go Online

- Optional.
- On the AC, configure the maximum number of APs that can concurrently go online to prevent an excessively high CPU usage caused by a large number of CAPWAP control packets.

Command	**capwap max-concurrent** *num*
Parameter Description	*num*: indicates the maximum number of APs that can concurrently go online. The number ranges from 1 to 200.
Defaults	50
Command Mode	AC configuration mode
Usage Guide	If a large number of APs go online concurrently, the CPU usage of the AC may increase or even reach 100%. Consequently, tunnels of APs that are already online will be disconnected due to keepalive failures. You can use this command to limit the maximum number of APs go online concurrently.

↘ Configuring the Number of CAPWAP Discovery Packets That Can Be Processed by an AC

- Optional.
- Configure the maximum number of discovery packets that can be processed by an AC on the AC to prevent exceedingly high CPU usage caused by considerable CAPWAP control packets.
- Run the ***capwap disc-concurrent*** *num* command to configure the number of discovery packets that can be processed.

Command	**capwap disc-concurrent** *num*
Parameter Description	The number of discovery packets that can be processed per second depends on the product capacity.
Defaults	The default value varies with the capacity value, for example, the default value is **256** for the WS7800.
Command Mode	AC global configuration mode

Usage Guide	The CAPWAP module needs to restrict the discovery packet processing concurrency based on the AC capacity, to prevent discovery packet attacks.

Verification

- Run the **show running-config** command to display the configurations.

Configuration Example

↘ Configuring the Maximum Number of APs That Can Concurrently Go Online

Configuration Steps	● On the AC, configure the maximum number of APs that can concurrently go online.
AC	`Ruijie(config-ac)#capwap max-concurrent 100`
Verification	● On the AC, run the **show running-config** command to display the configurations.
AC	`!` `ac-controller` `capwap max-concurrent 100` `!`

Common Errors

- N/A

3.4.12 Configuring CAPWAP Fragmentation

Configuration Effect

- After a packet is encapsulated on the CAPWAP tunnel, the packet length may exceed the IP MTU, and will be fragmented at the IP layer. When the IP MTUs of multiple nodes on the link are inconsistent, the packet may be fragmented and reassembled for several times, which reduces the packet forwarding performance. After CAPWAP fragmentation is enabled, the packet will be fragmented when encapsulated on the CAPWAP channel. The CAPWAP packet length is specified as the minimum IP MTU on the link, thereby avoiding fragmentation at the IP layer.

Notes

- If the configured MTU is too small, a lot of fragmented packets will be generated, affecting the packet forwarding performance. Even worse, large packets may fail to be transmitted. Therefore, it is important to determine the size of the MTU.
- The configured CAPWAP MTU must be equal to or smaller than the IP MTU at the egress of the device; otherwise, IP fragmentation will be performed after CAPWAP fragment. The minimum IPv6 MTU is 1280, that is, the minimum path MTU is 1280. Therefore, the CAPWAP MTU must be equal to or greater than 1280.

Configuration Steps

Configuring the Path MTU of the CAPWAP Tunnel

- (Optional) Enter the AP or AP group configuration mode, and run the **capwap mtu** command to configure the path MTU of the CAPWAP tunnel.
- If the length of the packet encapsulated on the CAPWAP tunnel exceeds the path MTU of the CAPWAP tunnel, the packet will be fragmented on the CAPWAP tunnel. When configuring the path MTU of the CAPWAP tunnel on the AC, this path MTU must be set to the minimum IP MTU on the tunnel; otherwise, IP fragmentation and reassembly are performed again during packet forwarding, reducing the forwarding performance.

Command	**capwap mtu** *num*
Parameter Description	*num*: indicates the path MTU of the CAPWAP tunnel. The value ranges from 68 to 1500. The unit is byte.
Defaults	The default size of the MTU is 1500 bytes.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Enabling CAPWAP Fragmentation

- Optional.
- When multiple IP MTU nodes exist on the transmission network, it is recommended that CAPWAP fragmentation be enabled on the AC, and the CAPWAP MTU be set to the path MTU.
- After a packet is encapsulated on the CAPWAP tunnel, the packet length may exceed the IP MTU, and will be fragmented at the IP layer. When the IP MTUs of multiple nodes on the link are inconsistent, the packet may be fragmented and reassembled for several times, which reduces the packet forwarding performance. You can run this command to enable CAPWAP fragmentation. After this function is enabled, the packet will be fragmented when encapsulated on the CAPWAP channel. The CAPWAP packet length can be specified in the **capwap mtu** command as the minimum IP MTU on the link, thereby avoiding fragmentation at the IP layer.

Command	**capwap fragment enable**
Parameter Description	N/A
Defaults	CAPWAP fragmentation is disabled by default.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Verification

- Check the detailed information about the CAPWAP to learn the MTU of the CAPWAP tunnel and whether the fragmentation function is enabled.
- Alternatively, run the **show ap-config running** command to check whether CAPWAP fragmentation is configured.

Configuration Example

Configuring the MTU of AP1 and Enabling the Fragmentation Function

Configuration Steps	● Set the path MTU of AP1 to 1200 bytes on the AC. ● Enable CAPWAP fragmentation of AP1 on the AC.
AC	`Ruijie(config)# ap-config AP1` `Ruijie(config-ap)# capwap mtu 1200` `Ruijie(config-ap)# capwap fragment enable`
Verification	Use the **show ap-config running** command to display the configurations.
AC	`!` `capwap fragment enable` `capwap mtu 1200` `!`

Common Errors

- N/A

3.4.13 Configuring CAPWAP Encryption

Configuration Effect

- Disable the encryption function on the CAPWAP control channel to analyze packets when the network is faulty.

Notes

N/A

Configuration Steps

Configuring the Encryption Function on the CAPWAP Control Channel

- Optional.
- On the AC, you can disable the encryption function on the CAPWAP control channel to analyze packets for troubleshooting purpose when the network is faulty.

Command	**capwap dtls enable**
Parameter Description	N/A
Defaults	By default, the DTLS encryption function is enabled on the CAPWAP control channel.
Command Mode	AC configuration mode

Usage Guide	By default, the DTLS encryption function is enabled on the CAPWAP control channel to ensure security of interaction between the AC and the AP. In special cases, you can disable the encryption function on the CAPWAP control channel to facilitate tests.

Verification

- Check the detailed information about the CAPWAP tunnel to determine the encryption policy of the control channel and the data channel.
- Run the **show running-config** command to check whether encryption is enabled on the control channel.

Configuration Example

↘ Enabling Encryption on the AP Data Channel and Disabling Encryption on the Control Channel

Configuration Steps	● On the AC, disable the encryption function on the AP control channel.
AC	`Ruijie(config-ap)# no capwap dtls enable`
Verification	● On the AC, run the **show running-config** command to check whether the encryption function is disabled on the control channel.
AC	`Ruijie#show running-config` `!` `no capwap dtls enable`

Common Errors

- N/A

3.4.14 Configuring CAPWAP Access Control

Configuration Effect

- Configure the maximum number of APs that can concurrently go online.

Notes

- If the configured value is too small, the total online duration of all APs connected to the AC will be relatively long.

Configuration Steps

↘ Configuring the Maximum Number of APs That Can Concurrently Go Online

- Optional.
- On the AC, configure the maximum number of APs that can concurrently go online to prevent an excessively high CPU usage caused by a large number of CAPWAP control packets.

Command	**capwap max-concurrent** *num*
Parameter Description	*num*: indicates the maximum number of APs that can concurrently go online. The number ranges from 1 to 200.
Defaults	50
Command Mode	AC configuration mode
Usage Guide	If a large number of APs go online concurrently, the CPU usage of the AC may increase or even reach 100%. Consequently, tunnels of APs that are already online will be disconnected due to keepalive failures. You can use this command to limit the maximum number of APs go online concurrently.

Verification

- Run the **show running-config** command to display the configurations.

Configuration Example

↘ Configuring the Maximum Number of APs That Can Concurrently Go Online

Configuration Steps	• On the AC, configure the maximum number of APs that can concurrently go online.
AC	`Ruijie(config-ac)#capwap max-concurrent 100`
Verification	• On the AC, run the **show running-config** command to display the configurations.
AC	`!` `ac-controller` `capwap max-concurrent 100` `!`

Common Errors

- N/A

3.4.15 Configuring the Echo Interval of the CAPWAP Tunnel

Configuration Effect

- (Optional) Configure the interval at which a keepalive packet is set.

Notes

- During deployment of the wireless network, the echo interval of the CAPWAP tunnel can be adjusted according to the network scale to properly plan the network convergence performance. During the adjustment, ensure that you have a good understanding about the network scale and confirm that the convergence is necessary. If a low echo interval is configured on a wireless network where a large number of APs are deployed, the network environment will be affected.

Configuration Steps

- (Optional) Enter the AP or AP group configuration mode for configuration.
- Configure the echo interval of the CAPWAP tunnel on the AC to control the keepalive period of the CAPWAP tunnel.

Command	**echo-interval** *seconds*
Parameter Description	*seconds*: indicates the echo interval of the CAPWAP tunnel. The value ranges from 5 to 255.
Defaults	30s
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	In a fit AP network structure, an AC is interconnected with an AP through the CAPWAP tunnel. The Echo Request and Echo Response packets are used between the AP and the AC to maintain the effectiveness of links. If other request packets are not transmitted, the AP sends an Echo Request packet to the AC at the interval specified by **echo-interval** to keep the CAPWAP tunnel alive. If the AP does not receive any Echo Response packet, the Echo Request packet will be retransmitted. The transmission interval starts at the initial transmission interval (3s or half of **echo-interval**, whichever the smaller), and then is doubled upon next retransmission. The maximum retransmission interval cannot exceed the half of **echo-interval** or 60s, whichever the smaller. If the AP does not receive the Echo Response packet when **max-retransmit (**the maximum retransmission times) is reached, it is determined that the CAPWAP tunnel is disconnected. That is, the keepalive failure time of the tunnel is equal to the keepalive time plus the retransmission interval. This command takes effect only when the tunnel is in Run state. By default, **echo-interval** is 30s, and **max-retransmit** is 5. If the Echo Response packet is not received 0s after the Echo Request packet is sent, the Echo Request packet will be retransmitted at the interval of 3s, 6s, 12s, 15s, and 15s, respectively. The same rule is observed to calculate the packet timeout time if **echo-interval** and **max-retransmit** are set to other values.

Verification

- Check the detailed information about the CAPWAP tunnel. The modified interval at which the keepalive packet is sent should be displayed.

Configuration Example

↘ Configuring the Echo Interval of the CAPWAP Tunnel

Configuration Steps	● On the AC, set the echo interval of the CAPWAP tunnel to 50s.
AC	`Ruijie(config)#ap-config AP0001` `Ruijie(config-ap)# echo-interval 50`
Verification	● On the AC, check the detailed information about the CAPWAP tunnel.
AC	`Ruijie#show capwap 1.1.1.1 detail` `Echo interval is 50 secs, Dead interval is 119 secs`

Common Errors

- N/A

3.4.16 Configuring the Maximum Retransmission Times of a CAPWAP Packet

Configuration Effect

- (Optional) Configure the maximum transmission times of a CAPWAP packet to adjust the keepalive time of the CAPWAP tunnel.

Notes

N/A

Configuration Steps

- (Optional) Enter the AP or AP group configuration mode for configuration.
- Configure the maximum transmission times of a CAPWAP packet to adjust the keepalive time of the CAPWAP tunnel.

Command	**capwap max-retransmit***num*
Parameter Description	*num*: indicates the maximum retransmission times of a CAPWAP packet
Defaults	5
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	If the AP does not receive any Echo Response packet after sending an Echo Request packet, the Echo Request packet will be retransmitted. The transmission interval starts at the initial transmission interval (3s or half of **echo-interval**, whichever the smaller), and then is doubled upon next retransmission. The maximum retransmission interval cannot exceed the half of **echo-interval** or 60s, whichever the smaller. If the AP does not receive the Echo Response packet when **max-retransmit (**the maximum retransmission times) is reached, it is determined that the CAPWAP tunnel is disconnected. You can configure the maximum transmission times of a CAPWAP packet to adjust the keepalive time of the CAPWAP tunnel. This command takes effect only when the tunnel is in Run state.

Verification

- Check the detailed information about the CAPWAP tunnel. The modified interval at which the keepalive packet is sent should be displayed.

Configuration Example

Configuring the Maximum Retransmission Times of a CAPWAP Packet

Configuration Steps	● Set the maximum retransmission times of AP1 to 20.
AC	`Ruijie(config)#ap-config AP1` `Ruijie(config-ap)# capwap max-retransmit 20`
Verification	● On the AC, check the detailed information about the CAPWAP tunnel.
AC	`Ruijie#show capwap 1.1.1.1 detail` `Config maxretransmit 20`

Common Errors

- N/A

3.4.17 Configuring the AC Discovery Mode

Configuration Effect

- An AP can send discovery packets of a recommended type, DHCP packets, DNS packets, packets carrying the statically configured AC IP address, and packets of other types (for example, broadcast and multicast packets) to an AC. An AC can be configured to respond only to certain types of discovery packets. Only APs receiving responses from an AC can perceive that the AC is valid, and these APs can establish CAPWAP tunnels to the AC.

Notes

- If the AC discovery mode is set to supporting none of the discovery packets, an AP cannot connect to an AC using discovery packets.

Configuration Steps

Configuring AC Discovery via a Recommended Type of Discovery Packets

- Optional.

Command	**capwap discovery-type ac-referral { allow | forbidden}**
Parameter Description	**allow**: indicates that this type of discovery packets can be used to discover an AC. **forbidden**: indicates that this type of discovery packets cannot be used to discover an AC.
Defaults	An AP can send discovery packets of a recommended type to discover an AC by default.

Command Mode	AC configuration mode
Usage Guide	N/A

Configuring AC Discovery via Discovery Packets

- Optional.
- After this command is configured, configurations of other discovery types will be overwritten.

Command	**capwap discovery-type all { allow | forbidden}**
Parameter Description	**allow**: indicates that discovery packets can be used to discover an AC. **forbidden**: indicates that discovery packets cannot be used to discover an AC.
Defaults	An AP can send discovery packets to discover an AC by default.
Command Mode	AC configuration mode
Usage Guide	N/A

Configuring AC Discovery via DHCP Packets

- Optional.

Command	**capwap discovery-type dhcp { allow | forbidden}**
Parameter Description	**allow**: indicates that DHCP packets can be used to discover an AC. **forbidden**: indicates that DHCP packets cannot be used to discover an AC.
Defaults	An AP can send DHCP packets to obtain the AC address and discover the AC by default.
Command Mode	AC configuration mode
Usage Guide	N/A

Configuring AC Discovery via DNS Packets

- Optional.

Command	**capwap discovery-type dns { allow | forbidden}**
Parameter Description	**allow**: indicates that DNS packets can be used to discover an AC. **forbidden**: indicates that DNS packets cannot be used to discover an AC.
Defaults	An AP can send DNS packets to obtain the AC address and discover the AC by default.
Command Mode	AC configuration mode
Usage Guide	N/A

Configuring AC Discovery via Packets Carrying the Statically Configured AC IP Address

- Optional.

Command	**capwap discovery-type static-config { allow | forbidden}**

Parameter Description	**allow**: indicates that packets carrying the statically configured AC IP address can be used to discover an AC. **forbidden**: indicates that packets carrying the statically configured AC IP address cannot be used to discover an AC.
Defaults	An AP can send packets carrying the statically configured AC IP address to discover the AC by default.
Command Mode	AC configuration mode
Usage Guide	N/A

Configuring AC Discovery via Discovery Packets of Other Types

- Optional.
- Configure other AC discovery modes, such as the broadcast or multicast mode.

Command	**capwap discovery-type unknown { allow | forbidden}**
Parameter Description	**allow**: indicates that broadcast or multicast discovery packets can be used to discover an AC. **forbidden**: indicates that broadcast or multicast discovery packets cannot be used to discover an AC.
Defaults	An AP can send broadcast or multicast packets to discover an AC by default.
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to check whether the configuration is successful.

Configuration Example

Forbidding an AP to Send Discovery Packets of a Recommended Type to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send discovery packets of a recommended type to discover the AC.
AC	`Ruijie(config)# ac-controller` `Ruijie(config-ac)# capwap discovery-type ac-referral forbidden`
Verification	● Display the AC configurations.
AC	`Ruijie#show running-config` `!` `ac-controller` `capwap discovery-type ac-referral forbidden` `!`

Forbidding an AP to Send Discovery Packets to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send discovery packets to discover the AC.
AC	Ruijie(config)# ac-controller Ruijie(config-ac)# capwap discovery-type all forbidden
Verification	● Display the AC configurations.
AC	Ruijie#show running-config ! ac-controller capwap discovery-type all forbidden !

Forbidding an AP to Send DHCP Packets to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send DHCP packets to obtain the AC address and discover the AC.
AC	Ruijie(config)# ac-controller Ruijie(config-ac)# capwap discovery-type dhcp forbidden
Verification	● Display the AC configurations.
AC	Ruijie#show running-config ! ac-controller capwap discovery-type dhcp forbidden !

Forbidding an AP to Send DNS Packets to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send DNS packets to obtain the AC address and discover the AC.
AC	Ruijie(config)# ac-controller Ruijie(config-ac)# capwap discovery-type dns forbidden
Verification	● Display the AC configurations.
AC	Ruijie#show running-config ! ac-controller capwap discovery-type dns forbidden !

Forbidding an AP to Send Packets Carrying the Statically Configured AC IP Address to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send packets carrying the statically configured AC IP address to discover the AC.
AC	`Ruijie(config)# ac-controller` `Ruijie(config-ac)# capwap discovery-type static-config forbidden`
Verification	● Display the AC configurations.
AC	`Ruijie#show running-config` `!` `ac-controller` `capwap discovery-type static-config forbidden` `!`

↘ Forbidding an AP to Send Other Types of Discovery Packets to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send other types of discovery packets to discover the AC.
AC	`Ruijie(config)# ac-controller` `Ruijie(config-ac)# capwap discovery-type unknown forbidden`
Verification	● Display the AC configurations.
AC	`Ruijie#show running-config` `!` `ac-controller` `capwap discovery-type unknown forbidden` `!`

Common Errors

Displays all downlink ports of i-Share+ APs	**show ap-config summary slot interface**

4 Configuring WBS

4.1 Overview

The Wireless Basic Service (WBS) is used to configure wireless-specific parameters on access controllers (ACs) when thin access points (APs) are deployed.

Link integrity detection is a basic service of the WBS. It detects the wired uplinks on APs. When the links are disconnected, the access services of the APs are stopped to force users offline. When the links are restored, the APs continue to provide wireless access services. Enabling link integrity detection in a fit AP architecture with dense AP deployment helps reduce the network disconnection time and improve user experience.

Protocols and Standards

- 802.11n: Enhancements for Higher Throughput
- 802.11ac：Enhancements for Very High Throughput for Operation in Bands below 6 GHz
- 802.11ax：Enhancements for High Efficiency WLAN

4.2 Applications

Application	Description
Configuring Fit APs	Run commands on ACs to configure the parameters of fit APs.
Enabling Link Integrity Detection	Enable link integrity detection in a fit AP architecture to improve the quality of service (QoS) of wireless access.

4.2.1 Configuring Fit APs

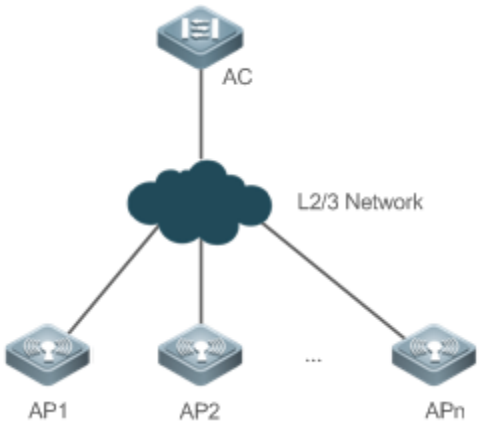
Scenario

Configure fit APs. Administrators can manage the configurations of fit APs on an AC in a centralized manner. Assume that a network has the following deployment requirements:

1. Allow the AC to monitor the status of the feeder links on i-Share APs.
2. Prevent stations (STAs) with received signal strength indication (RSSI) smaller than 20 from accessing the network.
3. Enable short guard interval (GI) in 20 MHz.
4. Prevent the use of low data rates, such as 1 Mbps, 2 Mbps, and 5.5 Mbps.

Figure 4-1 shows the fit AP networking topology.

Figure 4-1 Fit AP Networking Topology



Deployment

Main configuration points on the AC:

1. Enable i-Share antenna feeder link detection for all the APs and set the detection interval to an expected value.
2. Run **response-rssi** for the radios of all the APs and set the threshold to 20 dB.
3. Run **short-gi enable** for the radios of all the APs and set the bandwidth to 20 MHz.
4. Disable the use of the 1 Mbps, 2 Mbps, and 5.5 Mbps data rates for 802.11b/g network users.

4.2.2 Enabling Link Integrity Detection

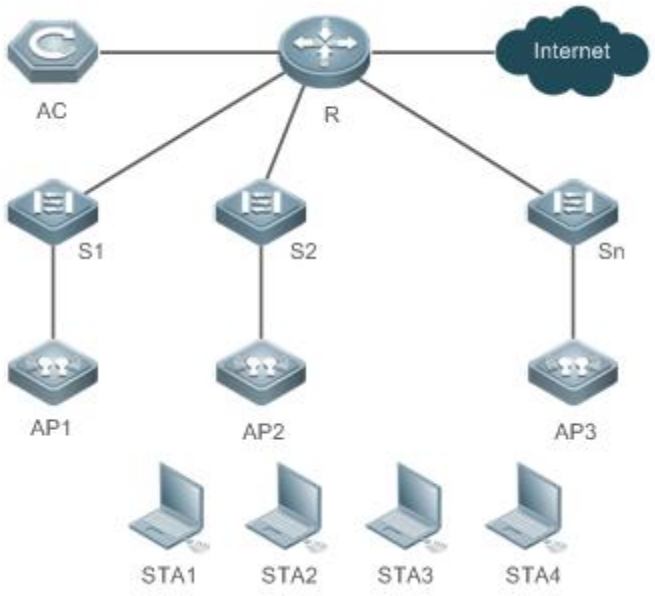
Scenario

Enable link integrity detection on wireless networks with a fit AP architecture.

See Figure 4-2.

- An AC is connected to the Internet through a router. AP1, AP2, and AP3 are connected to the router through three switches and associated with the AC.
- Station 1 (STA1) is associated with AP1, STA2 and STA3 are associated with AP2, and STA4 is associated with AP3. The STAs access the Internet through the AC.

Figure 4-2



Remarks	R is an egress router. S1, S2, and S3 are Layer-2 switches and function as the access devices for APs. AP1, AP2, and AP3 are directly connected to S1, S2, and S3.

Deployment

- Layer-2 switches provide the access service to APs.
- Router R sets up connections between ACs and APs and between STAs and the Internet.

4.3 Features

Basic Concepts

A-MPDU

The 802.11n standards adopt the aggregate MAC protocol data unit (A-MPDU). Multiple MPDUs are aggregated into an A-MPDU, and only one PHY header is retained whereas the PHY headers of other MPDUs are removed. In this way, the additional information of the PHY header of each MPDU to be transmitted is reduced, and the number of ACK frames is also reduced, which mitigates the burden and improves network throughput.

MCS

The physical layer of 802.11n supports high data transmission rates and is compatible with 802.11a/b/g rates. The many different speeds supported at the physical layer of 802.11n are called modulation and coding scheme (MCS) rates.

Beacon

The APs on wireless local area networks (WLANs) periodically send beacon frames externally. The beacon frames contain AP information. Wireless STAs receive beacon frames to discover WLANs.

RSSI

RSSI indicates the quality of wireless connections.

Country Code

A country code identifies a country with radio frequency (RF) usage. RFs, channels, and powers vary with different country codes. Before you configure an AP, determine the country code that the AP supports. If the configured country code is changed, the RFs, channels, and powers mapped to the country code are also changed.

Frequency Band

FR transmission in the 2.4 GHz and 5 GHz frequency bands is supported.

Channel

Wireless channels transmit RF medium between APs and wireless STAs. The use of channels varies with different countries and frequency bands. In China, the 2.4 GHz frequency band can be configured with 13 channels (channel 1 to channel 13), and the 5 GHz frequency band can be configured with five channels (channels 149, 153, 157, 161, and 165). The overlapping channels in the 2.4 GHz frequency band generate interference. It is recommended that these channels be configured as non-overlapping channels (for example, channels 1, 6, and 11) to avoid radio signal collision. The five channels in the 5 GHz frequency band do not overlap or generate interference.

Transmit Power

Transmit power indicates the strength of the RF signals transmitted by an AP. It is proportional to the radio signal coverage area of the AP.

Timeslot Type

Channel contention may occur when multiple STAs send data on the same WLAN. To avoid this problem, STAs are required to check the idle state of channels before sending data. If an STA detects that a channel is idle, the STA does not send data until the backoff time has elapsed. The backoff time is a random integer of the slot time (which is an operation time unit specified in the Media Access Control [MAC] protocol). The value of the backoff time is automatically subtracted by 1 each time after the slot time has elapsed. When the backoff time is reduced to 0, the STA starts sending data. The slot time on WLANs is classified into 20 μs and 9 μs, with the later being called short slot time.

Antenna Transmit/Receive Types

You can configure some antennas on an RF card to transmit signals and the other antennas to receive signals.

Short GI

802.11n adds optional support for a 0.4 μs guard interval, compared to the standard 0.8 μs guard interval.

Fragmentation Threshold

To increase the transmission success rate, the IEEE 802.11 MAC protocol supports the fragmentation of packets before transmission. Packets are fragmented according to a threshold, which reduces the interference probability and saves bandwidth resources during retransmission.

RTS

To avoid channel conflicts and the resulting data transmission failures, the IEEE 802.11 MAC protocol provides a handshake protocol called Request To Send/Clear To Send (RTS/CTS). When STA A needs to send data to STA B, it first sends an RTS frame. STA B responds with a CTS frame if it permits STA A to send data. After receiving the CTS frame, STA A starts sending data. When multiple STAs send RTS frames to the same STA, only the STAs that receive CTS frames are permitted to send data. The STAs that do not receive CTS frames can resend RTS frames after a time because a channel conflict is considered to have occurred.

PHY Protection Modes

Frames can be transmitted in Greenfield mode or hybrid mode. The hybrid mode is intended to support compatibility with other physical layers, and the Greenfield mode is used to transmit physical layer headers at high speeds. A device which uses the high-throughput (HT) hybrid mode can transmit frames in 802.11a/b/g and 802.11n modes. Such a device first transmits a conventional format preamble, followed by an HT format preamble. The device must send a conventional CTS-to-Self or RTS/CTS frame before transmitting data. These protection mechanisms enable 802.11a/b/g devices, including those devices not connected to APs in HT hybrid mode to sense the busy state of channels.

Preamble Type

A preamble is a group of bits in a packet header, used to synchronize the transmission signals between the transmit end and receive end. You can configure the preamble type (long or short) that an AP supports. The data frames with long preambles take a longer time to transmit than the data frames with a short preamble.

U-APSD

802.11e introduces Wi-Fi multimedia power save (WMM-PS) to reduce the delay of the services with high real-time requirements during the power management process. WMM-PS adopts the Unscheduled Automatic Power Save Delivery (U-APSD) technology to disable the transmission of radio signals during most of the time, which extends the battery life. U-APSD is an enhancement of the 802.11 power saving mechanism.

MU-MIMO

MU-MIMO is short for Multi-User Multiple-Input Multiple-Output. 802.11ac uses downlink MU-MIMO to enable an AP to send data to multiple STAs through beamforming. 802.11ax uses uplink MU-MIMO to enable multiple STAs to send data to an AP.

OFDMA

OFDMA is short for Orthogonal Frequency Division Multiple Access. OFDMA is a multi-user version of the popular orthogonal frequency-division multiplexing (OFDM) digital modulation scheme. Multiple access is achieved in OFDMA by assigning subsets of subcarriers to individual users. This allows simultaneous low-data-rate transmission from several users.

Overview

Feature	Description
Configuring i-Share Antenna Feeder Link Detection	Checks the status of the feeder links on i-Share APs.
Configuring STA Access Control	Controls the access of specified wireless STAs.
Configuring AP RF Parameters	Configures the RF parameters for APs or radios.
Configuring Data Rate Control Parameters	Configures the RF parameters of data rate control.
Configuring Power-Save Parameters	Sets the parameters of power saving.
Enabling Link Integrity Detection	Detects the integrity of links to improve the wireless service quality.
Configuring E-Bag Parameters	Provides a command to quickly configure E-bag network optimization in one-click mode, which improves user experience.
Configuring WLANs in One-Click Mode	Provides the one-click WLAN configuration feature to perform fast configuration on devices with zero configurations.

4.3.1 Configuring STA Access Control

Working Principle

Ruijie Networks provides wireless STA access control.

Wireless STAs search for APs through active scan and passive scan.

- Active scan: A wireless STA sends a Probe Request frame to request access to an AP, which will respond with a Probe Response frame.
- Passive scan: APs broadcast beacon frames periodically. Wireless STAs listen to beacon frames and initiate connections to APs.

To control the network coverage areas of APs and improve the transmission quality of radio signals, the following methods are used to limit the access of wireless STAs:

- Control the beacon frame broadcast ranges of APs to limit the access of long-distance wireless STAs.
- Control the minimum RSSI value applied to wireless STAs during the access process. The STAs which send request frames with RSSI smaller than the minimum value are denied access.
- Control the minimum RSSI value applied to wireless STAs during the data transmission process. The STAs which send data frames with RSSI smaller than the minimum value are forced offline. Then the STAs can roam to other APs with better radio signals.

4.3.2 Configuring AP RF Parameters

You can configure the RF parameters for APs and radios.

Working Principle

A-MPDU

The 802.11n standards adopt A-MPDU. Multiple MPDUs are aggregated into an A-MPDU, and only one PHY header is retained whereas the PHY headers of other MPDUs are removed. In this way, the additional information of the PHY header of each MPDU to be transmitted is reduced, and the number of ACK frames is also reduced, which mitigates the burden and improves network throughput.

MCS

In 802.11n, RF rates are configured by using the index values of the MCS, which is used to express the communication rates on WLANs. The MCS is a rate table. The table columns show the factors of concern that affect communication rates, and the table rows show the MCS indexes. Each MCS index maps a physical transmission rate which is determined by a group of parameters. For the description of all the MCS rate tables, see the *IEEE P802.11n D2.00*.

Wireless Channel

Wireless channels transmit RF medium between APs and wireless STAs. The use of channels varies with different countries and frequency bands. In China, the 2.4 GHz frequency band can be configured with 13 channels (channel 1 to channel 13), and the 5 GHz frequency band can be configured with five channels (channels 149, 153, 157, 161, and 165). The overlapping channels in the 2.4 GHz frequency band generate interference. It is recommended that these channels be configured as non-overlapping channels (for example, channels 1, 6, and 11) to avoid radio signal collision. The five channels in the 5 GHz frequency band do not overlap or generate interference.

Packet Fragmentation

To increase the transmission success rate, the IEEE 802.11 MAC protocol supports the fragmentation of packets before transmission. Packets are fragmented according to a threshold, which reduces the interference probability and saves bandwidth resources during retransmission.

RTS/CTS

To avoid channel conflicts and the resulting data transmission failures, the IEEE 802.11 MAC protocol provides a handshake protocol called RTS/CTS. When STA A needs to send data to STA B, it first sends an RTS frame. STA B responds with a CTS frame if it permits STA A to send data. After receiving the CTS frame, STA A starts sending data. When multiple STAs send RTS frames to the same STA, only the STAs that receive CTS frames are permitted to send data. The STAs that do not receive CTS frames can resend RTS frames after a time because a channel conflict is considered to have occurred.

If each STA implements RTS/CTS handshake before sending data, many RTS frames will occupy channel bandwidths. To avoid this problem, you can configure an RTS threshold to specify the frame length of transmitted data. If an STA sends data with a frame length smaller than the RTS threshold, the STA will not implement RTS/CTS handshake.

Beacon

The APs on WLANs periodically send beacon frames externally. The beacon frames contain AP information. Wireless STAs receive beacon frames to discover WLANs.

Preamble Type

A preamble is a group of bits in a packet header, used to synchronize the transmission signals between the transmit end and receive end. You can configure the preamble type (long or short) that an AP supports. The data frames with long preambles take a longer time to transmit than the data frames with a short preamble.

Timeslot Type

Channel contention may occur when multiple STAs send data on the same WLAN. To avoid this problem, STAs are required to check the idle state of channels before sending data. If an STA detects that a channel is idle, the STA does not send data until the backoff time has elapsed. The backoff time is a random integer of the slot time (which is an operation time unit specified in the MAC protocol). Assume that the random integer is 3. The value of the backoff time is automatically subtracted by 1 each time after the slot time has elapsed. When the backoff time is reduced to 0, the STA starts sending data. Reducing the slot time can reduce the overall backoff time and increase network throughput.

Channel Bandwidth

In 802.11n, two 20 MHz bandwidths are combined into a 40 MHz bandwidth, which can be used as two 20 MHz bandwidths. (One 20 MHz bandwidth is the primary bandwidth, and the other is the secondary bandwidth. Data can be received and transmitted by using the 40 MHz bandwidth or two individual 20 MHz bandwidths.) In this way, data rates are doubled and wireless network throughput is increased.

GI

802.11n adds optional support for a 0.4 μs guard interval, compared to the standard 0.8 μs guard interval.

802.11ax supports three types of guard interval: 0.8us, 1.6us, and 3.2us.

Country Code

A country code identifies a country with RF usage. RFs, channels, and powers vary with different country codes. Before you configure an AP, determine the country code that the AP supports. If the configured country code is changed, the RFs, channels, and powers mapped to the country code are also changed.

Antenna Transmit/Receive Types

APs use different quantities of antennas for transmitting and receiving signals, which enables APs to use two or three spatial streams to transmit signals in 802.11n mode, thus improving data transmission performance.

Internal Antenna and External Antenna

Internal antennas are integrated inside the enclosures of APs, and external antennas are connected to the reserved hardware interfaces of APs. External antennas achieve longer transmission distances than internal antennas with the same transmission power.

Omnidirectional Antenna and Directional Antenna

- An omnidirectional antenna radiates equally in all directions. A directional antenna radiates in a specific direction with a cone-shaped radiation range.**Maximum Distance of Radio Transmission Between AP Radios and the Peer End**

Radio signals are transmitted in space at the speed of light. The longer the distance of radio transmission between AP radios and the peer end, the longer time it takes to transmit radio packets in space and the longer the timeout time for APs to wait for ACK and CTS frames. The timeout time must be adjusted based on the distance of radio transmission between AP radios and the peer end; otherwise, radio data transmission will fail. A very long timeout time will cause resource waste on the air interface when APs are still waiting for ACK and CTS frames. Configuring Data Rate Control Parameters

You can configure the RF parameters of data rate control.

Working Principle

802.11 is the industry standards that the Institute of Electrical and Electronics Engineers (IEEE) developed for WLAN communications. 802.11x is an improvement over 802.11. The main transmission standards include 802.11b, 802.11a, 802.11g, and 802.11n.

1. 802.11b

The operating band is 2.4 GHz, and the data transmission rate can reach 11 Mbps, which can be reduced to 5.5 Mbps, 2 Mbps, or 1 Mbps based on actual requirements.

2. 802.11a

The operating band is 5 GHz, and the data transmission rate can reach 54 Mbps, which can be reduced to 48 Mbps, 36 Mbps, 24 Mbps, 18 Mbps, 12 Mbps, 9 Mbps, or 6 Mbps based on actual requirements.

3. 802.11g

The operating band is 2.4 GHz, and the data transmission rate can reach 54 Mbps, which can be reduced to 48 Mbps, 36 Mbps, 24 Mbps, 18 Mbps, 12 Mbps, 9 Mbps, or 6 Mbps based on actual requirements. 802.11g STAs are backward compatible with 802.11b.

4.3.3 Configuring Power-Save Parameters

Working Principle

↘ DTIM Period

A delivery traffic indication map (DTIM) is a flag bit in a beacon frame, used to determine the interval at which an AP sends broadcast or multicast frames. APs buffer the data that wireless STAs in dormant state need to receive according to the DTIM period. After the DTIM period has elapsed, APs send the buffered data to wireless STAs.

The DTIM period is expressed based on the number of sent beacon frames. Assume that the DTIM period is set to 3. APs send broadcast or multicast frames each time after three beacon frames are sent.

↘ U-APSD Power Saving

U-APSD is an improvement over the power saving mode. When clients are associated with ACs, the clients can configure which ACs have the trigger attribute, which ACs have the delivery attribute, and the maximum number of packets to be sent after trigger. The trigger and delivery attributes can be modified when flows are created through connection access control (CAC). When a client sleeps, the delivery-enabled AC packets destined for the client are buffered. To retrieve the buffered packets, the client needs to send trigger-enabled AC packets. After receiving the trigger-enabled AC packets, the AP sends

the buffered packets according to the to-be-sent packet quantity determined during the access process. Other AC packets than delivery-enabled AC packets are stored and transmitted in accordance with the 802.11 standards.

4.3.4 Enabling Link Integrity Detection

APs are wireless access devices without the switching feature. They implement all functions of the physical layer and partial functions of the MAC layer. A fat AP or fit AP has only one wired uplink, which is the data channel allowing STAs to access the AP. When the wired uplink is disconnected because of a fault, all the wireless STAs connected to the AP cannot access the Internet.

Wireless STAs cannot sense link disconnections immediately or take measures; as a result, the network connection cannot be restored for a long time.

Link integrity detection is designed to solve this problem.

Working Principle

The link integrity detection function continuously detects the status of the wired uplinks on APs. When a wired uplink is disconnected, the RF interface of the AP is disabled to stop the access service. The wireless STAs associated with the AP are forced offline and have to reconnect to other normal APs.

When the wired uplink is recovered, the link integrity detection function enables the RF interface of the AP again to restore the wireless access service.

Link integrity detection enables the wireless STAs that are associated with APs with disconnected wired uplinks to reconnect to other normal APs.

4.3.5 Configuring E-Bag Parameters

You can configure the E-bag parameters for APs and radios.

Working Principle

You can run a command to quickly configure E-bag network optimization in one-click mode, which improves user experience.

↘ A-MPDU

A-MPDU is short for aggregate MAC protocol data unit.

↘ LDPC

A low-density parity-check (LDPC) code is a linear error correcting code. Being easy to use and with low complexity, this coding method adopts the forward error correction (FEC) technology to improve the coding reliability and gains. LDPC was developed at the beginning of the 1960 and supports the transmission of information in noisy frequencies with massive background or content damage. It also greatly reduces the probability of information loss during transmission in frequencies with serious noise interference. However, a small number of STAs are not compatible with LDPC, and enabling LDPC will result in packet loss.

↘ STBC

Space time block coding (STBC) is a technique used in wireless communications to transmit multiple copies of a data stream across a number of antennas at different time points to improve the reliability of data transmission by means of time diversity and space diversity. The outstanding advantage of STBC is the use of maximum likelihood decoding to obtain complete antenna gains. Some STAs may not be compatible with STBC.

A-MPDU Software Retransmission Times

The A-MPDU software retransmission mechanism is designed to avoid the loss of sub-frames in wireless communications. The greater the retransmission times, the lower the probability of sub-frame loss. If packets are retransmitted frequently, the burden on the air interface is increased, which affects the real-time transmission of packets on the air interface. You can increase the retransmission times if you need to avoid packet loss when there is a high probability of sub-frame loss.

A-MPDU-RTS

The RTS protection feature of A-MPDU prevents resource waste on the air interface caused by packet collision due to hidden nodes. Because RTS interaction consumes air interface resources and has resulting adverse impact in many application scenarios, this feature is disabled by default. Enable RTS protection only when the resource waste on the air interface caused by hidden nodes is greater than the resource consumption of RTS interaction on the air interface.

Single-Time Received Ethernet Packet Quantity

A command is provided to adjust the number of Ethernet packets received at a single time. Increasing Ethernet packet reception can improve network performance but may reduce APs' ability to handle key packets in real time. You can reduce Ethernet packet reception when the requirements for performance are not high but user concurrency and real-time packet handling are demanded. In this case, it is recommended that the single-time received Ethernet packet quantity be set to 25.

4.3.6 Configuring WLANs in One-Click Mode

The one-click WLAN configuration feature allows you to perform fast configuration on devices with zero configurations.

Working Principle

autowifi

Perform the following configuration on an AC:

1. Division of virtual local area networks (VLANs): On the AC, configure VLAN1 as the VLAN for APs and VLAN2 as the VLAN for STAs.
2. Address pool: On the AC, configure the 192.168.1.0 network segment as the address pool for APs and configure the 192.168.2.0 network segment as the network segment for STAs. The default IP addresses of VLAN1 and VLAN2 are 192.168.1.1 and 192.168.2.1 respectively. The default management IP address is 88.88.88.88.
3. WLAN configuration: Name the WLAN **autowifi**_*XXXX*. The last four characters are the last four digits of the MAC address of the AC. You can use wlan-id 1.
4. Security: By default, WPA2 encryption is used. The password is **autowifi**.
5. WLAN-VLAN mapping: On the AC, configure the mapping between wlan-id 1 and VLAN2 in the group named **ap-group default**.

6. Service: Enable the Dynamic Host Configuration Protocol (DHCP) service.

4.3.7 Managing the Operating Frequency Band When Power Supply Is Insufficient

For an AP that requires the PoE+ mode but the power supply device negotiates not the PoE+ mode but the 15.4 W power, power supply may be insufficient if all RF modules provide services. When power supply is insufficient, the AP disables some RF modules (2.4 GHz or 5 GHz) based on its capabilities and external power supply conditions to ensure that other RF modules have sufficient power and can run properly. When the power supply mode is changed to PoE+, all RF modules are enabled and can run properly.

Working Principle

For an AP that requires the PoE+ mode but the negotiated power upon startup is 15.4 W, the AP disables some RF modules (2.4 GHz or 5 GHz) based on its capabilities. However, the AC can switch the operating frequency band of the AP, that is, switching between 2.4 GHz and 5 GHz.

4.4 Configuration

Configuration	Description and Command	
Configuring STA Access Control	(Optional) It is used to configure STA access control.	
	{**802.11a** | **802.11b**} **network** {**enable** | **disable**}	Enables or disables the 2.4 GHz or 5 GHz network.
	11asupport enable	Enables 802.11a support for specified AP radios in 5 GHz.
	11bsupport enable	Enables 802.11b support for specified AP radios in 2.4 GHz.
	11gsupport enable	Enables 802.11g support for specified AP radios on the 2.4 GHz network.
	11nasupport enable	Enables 802.11n support for specified AP radios in 5 GHz.
	11ngsupport enable	Enables 802.11n support for specified AP radios in 2.4 GHz.
	11acsupport enable	Enables 802.11ac support for specified AP radios.
	11axsupport enable	Enables 802.11ax support for specified AP radios.
	coverage-area-control	Configures the management frame power for APs.
	extra-coverage	Configures the third radio for user access.
	response-rssi	Configures the minimum RSSI for wireless STAs to connect to specified AP radios.

Configuration	Description and Command	
	assoc-rssi	Configures the minimum RSSI for wireless STAs to maintain connections to specified AP radios.
Configuring AP RF Parameters	(Optional) It is used to configure the RF parameters for APs.	
	802.11n a-mpdu enable	Enables A-MPDU for specified AP radios.
	802.11n mcs support	Configures the maximum 802.11n MCS index value for specified AP radios.
	802.11ac mcs support	Configures the maximum 802.11ac MCS index value for specified AP radios.
	802.11ax mcs support	Configures the maximum 802.11ax MCS index value for specified AP radios.
	antenna	Configures the antenna transmit/receive type for specified AP radios.
	external-antenna enable	Enables usage of external antennas for specified AP radios, and disables usage of internal antennas.
	antenna type	Configures an omnidirectional antenna or a directional antenna.
	beacon dtim-period	Configures the DTIM period for specified AP radios.
	beacon period	Configures the beacon frame transmission period for specified AP radios.
	chan-with	Configures bandwidth assignments for specified AP radios.
	channel	Configures channel assignments for specified AP radios.
	channel-switch	Configures channel switching.
	country	Configures the country code set supported by an AC or the country code used by AP radios.
	enable-radio	Enables specified or all AP radios.
	fragment-threshold	Configures the fragmentation threshold for specified AP radios.
	green-field enable	Enables the protection mode for specified AP radios.
	ofdma	Enables ofdma for the specified radio.
	power local	Configures the transmit power for specified AP radios.

Configuration	Description and Command	
	radio-optimize	Configures radio parameters, including power, channel and antenna type.
	radio-type	Specifies the operating band for specified AP radios.
	rts-threshold	Configures the RTS threshold for specified AP radios.
	short-gi	Enables short GI for specified AP radios.
	update-key-tsc enable	Enables TKIP Sequence Counter (TSC) update for APs during 802.11x re-authentication.
	peer-distance	Configures the maximum distance of wireless transmission between APs and the peer end.
	mu-mimo enable	Configures MIMO for multi users.
	mcell	Configures mcell.
Configuring Data Rate Control Parameters	(Optional) It is used to configure the parameters of data rate control.	
	802.11a network rate	Configures the data rate set supported by 802.11a STAs.
	802.11b network rate	Configures the data rate set supported by 802.11b STAs.
	802.11g network rate	Configures the data rate set supported by 802.11g STAs.
	mcast-rate	Configures the WLAN multicast rate.
	beacon rate	Configures the beacon frame transmission rate.
Configuring Power-Save Parameters	(Optional) It is used to configure the power-save parameters.	
	beacon dtim-period	Configures the DTIM period.
	apsd	Enables or disables U-APSD power saving.
Enabling Link Integrity Detection	(Mandatory) It is used to enable link integrity detection.	
	link-check enable	Enables link integrity detection.
Configuring E-Bag Parameters	(Optional) It is used to configure the parameters of E-bag.	
	ampdu-retries	Configures the A-MPDU software retransmission times.
	ampdu-rts	Enables or disables RTS protection for A-MPDU packets.

Configuration	Description and Command	
	eth-schd	Configures the single-time received Ethernet packet quantity for APs.
	ldpc	Enables or disables LDPC.
	stbc	Enables or disables transmit/receive STBC.
	ebag	Configures E-bag network optimization in one-click mode.
Configuring WLANs in One-Click Mode	⚠ (Optional) It is used to configure WLANs in one-click mode.	
	autowifi	Configures WLANs in one-click mode.
Managing the Operating Frequency Band When Power Supply Is Insufficient	**hap-poe enable radio** { **802.11a** | **802.11b** }	Switches to 2.4 GHz or 5 GHz.

4.4.1 Configuring STA Access Control

Configuration Effect

- Control the access of a specified type of wireless STAs to manage these wireless STAs conveniently.

Configuration Steps

↘ Enabling or Disabling the 2.4 GHz or 5 GHz Network

- Optional.
- Enable or disable the 2.4 GHz or 5 GHz network on an AC.
- The AC assigns the network settings to all the APs to instruct the APs to enable or disable the 2.4 GHz or 5 GHz network.

Command	{ **802.11a** | **802.11b**} **network** { **enable** | **disable** }
Parameter Description	N/A
Defaults	By default, the 2.4 GHz and 5 GHz networks are enabled.
Command Mode	AC configuration mode
Configuration Usage Guide	N/A

↘ Enabling 802.11a Support

- Optional.
- The configuration takes effect only when the AP radios operate in 5 GHz.
- On the AC, enable 802.11a support for specified APs.
- The AC assigns the settings to the APs to instruct the APs to support the access of 802.11a STAs in 5 GHz.

Command	**11asupport enable radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with 802.11a support. The value ranges from 1 to 96.
Defaults	By default, the access of 802.11a STAs is supported in 5 GHz.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration takes effect only when the AP radios operate in 5 GHz. The configuration is supported only by certain APs.

Enabling 802.11b Support

- Optional.
- The configuration takes effect only when the AP radios operate in 2.4 GHz.
- On the AC, enable 802.11b support for specified APs.
- The AC assigns the settings to the APs to instruct the APs to support the access of 802.11b STAs in 2.4 GHz.

Command	**11bsupport enable radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with 802.11b support. The value ranges from 1 to 96.
Defaults	By default, the access of 802.11b STAs is supported in 2.4 GHz.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration takes effect only when the AP radios operate in 2.4 GHz. The configuration is supported only by certain APs.

Enabling 802.11g Support

- Optional.
- The configuration takes effect only when the AP radios operate in 2.4 GHz.
- On the AC, enable 802.11g support for specified APs.
- The AC assigns the settings to the APs to instruct the APs to support the access of 802.11g STAs in 2.4 GHz.

Command	**11gsupport enable radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with 802.11g support. The value ranges from 1 to 96.
Defaults	By default, the access of 802.11g STAs is supported in 2.4 GHz.
Command Mode	AP configuration mode

Configuration Usage Guide	The configuration takes effect only when the AP radios operate in 2.4 GHz. The configuration is supported only by certain APs.

Enabling 802.11na Support

- Optional.
- The configuration takes effect only when the AP radios operate in 5 GHz.
- On the AC, enable 802.11na support for specified APs.
- The AC assigns the settings to the APs to instruct the APs to support the access of 802.11n STAs in 5 GHz.

Command	**11nasupport enable radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with 802.11na support. The value ranges from 1 to 96.
Defaults	By default, the access of 802.11n STAs is supported in 5 GHz.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration takes effect only when the AP radios operate in 5 GHz. The configuration is supported only by certain APs.

Enabling 802.11ng Support

- Optional.
- The configuration takes effect only when the AP radios operate in 2.4 GHz.
- On the AC, enable 802.11ng support for specified APs.
- The AC assigns the settings to the APs to instruct the APs to support the access of 802.11n STAs in 2.4 GHz.

Command	**11ngsupport enable radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with 802.11ng support. The value ranges from 1 to 96.
Defaults	By default, the access of 802.11n STAs is supported in 2.4 GHz.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration takes effect only when the AP radios operate in 2.4 GHz. The configuration is supported only by certain APs.

Enabling 802.11ac

- Optional.
- On the AC, enable 802.11ac support for specified APs.
- The AC delivers configuration to the APs to instruct the APs to support the access of 802.11ac STAs.

Command	**11acsupport enable radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with 802.11ac support. The value ranges from 1 to 96.
Defaults	Only the radios with even IDs support the access of 802.11ac STAs.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Enabling 802.11ax

- Optional.
- On the AC, enable 802.11ax support for specified APs.
- The AC delivers configuration to the APs to instruct the APs to support the access of 802.11ax STAs.

Command	**11axsupport enable radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with 802.11ax support. The value ranges from 1 to 96.
Defaults	Only the radios with even IDs support the access of 802.11ax STAs.
Command Mode	AP configuration mode, all-AP configuration mode
Configuration Usage Guide	N/A

Configuring the Management Frame Power for APs

- Optional.
- Perform the configuration only on the required device unless otherwise specified.
- On the AC, configure the management frame power for specified APs.
- The AC assigns the settings to the APs to instruct the APs to use the configured management frame transmit power. In this way, the signal coverage areas of the APs are controlled to limit the access of wireless STAs.

Command	**coverage-area-control** *power* [**radio** { *radio-id* | **802.11b | 802.11a** }]
Parameter Description	*power*: specifies the management frame power. The value ranges from 0 to 32, in the unit of dBm. *radio-id*: specifies the IDs of the radios assigned with channels. The value ranges from 1 to 96. **802.11b**: indicates that bandwidth is assigned to all the radios in 2.4 GHz. **802.11a**: indicates that bandwidth is assigned to all the radios in 5.8 GHz.
Defaults	By default, the management frame power for APs is 0 dBm.
Command Mode	AP configuration mode/AP group configuration mode

Configuration Usage Guide	N/A

Configuring the Minimum RSSI for Wireless STAs to Access APs

- Optional.
- On the AC, configure the minimum RSSI for wireless STAs to access specified AP.
- The AC assigns the settings to the APs to instruct the APs to use the configured minimum RSSI as the threshold for allowing the access of wireless STAs.

Command	**response-rssi** *rssi* **radio** {*radio-id* | *[802.11b* | *802.11a*]}
Parameter Description	*rssi:* specifies the minimum RSSI for wireless STAs to access APs. The value ranges from 0 to 100, in the unit of dB. *radio-id*: specifies the IDs of the radios assigned with the minimum RSSI. The value ranges from 1 to 96. *802.11b*: indicates that the minimum RSSI is assigned to all the radios in 2.4 GHz. *802.11a*: indicates that the minimum RSSI is assigned to all the radios in 5.8 GHz.
Defaults	By default, the RSSI is set to **0**, indicating that there is no RSSI limit on the access of wireless STAs.
Command Mode	AP configuration mode
Configuration Usage Guide	If you select **802.11b**, the minimum RSSI is configured for all the radios in 2.4 GHz. The settings take effect when the APs go online for the first time and are automatically applied to the radios. If you select **802.11a**, the condition is the same for the radios in 5.8 GHz.

Configuring the Minimum RSSI for Wireless STAs to Maintain Connections to APs

- Optional.
- On the AC, configure the minimum RSSI for wireless STAs to maintain connections to specified AP.
- The AC assigns the settings to the APs to instruct the APs to use the configured minimum RSSI as the threshold for maintaining the connections of wireless STAs.

Command	**assoc-rssi** *rssi* **radio** *radio-id*
Parameter Description	*rssi:* specifies the minimum RSSI for wireless STAs to maintain connections. The value ranges from 0 to 100, in the unit of dB. *radio-id*: specifies the IDs of the radios assigned with the minimum RSSI. The value ranges from 1 to 96.
Defaults	By default, the RSSI is set to **0**, indicating that there is no RSSI limit on the access of wireless STAs.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Configuring the Third Radio for User Access

- Optional.
- On the AC, configure the AP in high density scenario.
- The channel, antenna, power, bandwidth will be adjusted for better access experience.

Command	**extra-coverage enable**
Parameter Description	N/A
Defaults	The third radio is disabled by default.
Command Mode	AP configuration mode AP group configuration mode
Configuration Usage Guide	Use the **no** form of this command to disable the function. Use teh **default** form of this command to restore the default setting,

Verification

- Run **show ap-config running** *ap-name* to display the parameter settings of STA access control.

Configuration Example

↘ Configuring the Parameters of STA Access Control

Scenario **Figure 4-3**	 In Figure 4-3, an AC is connected to fit APs. On the AC, configure STA access control for all the APs according to the following step: 1. Disable the 2.4 GHz network.

	On the AC, configure STA access control for AP1 according to the following steps: 1. Enable the access of 802.11a and 802.11na STAs in 5 GHz 2. Enable the access of 802.11g and 802.11ng STAs in 2.4 GHz. 3. Enable the access of 802.11ac STAs. 4. Set the management frame power to 20 dBm. 5. Set the minimum RSSI for wireless STAs to access APs to 20 dB. 6. Set the minimum RSSI for wireless STAs to maintain connections to15 dB. 7. Enable the third radio for user access.
Configuration Steps	● Disable the 2.4 GHz network on the AC.
AC	Ruijie# configure terminal Ruijie(config)# ac-controller Ruijie(config-ac)# 802.11b network disable
	● Set the STA access control parameters for AP1 on the AC.
AC	Ruijie# configure terminal Ruijie(config)# ap-config AP1 Ruijie(config-ap)# 11asupport enable radio 2 Ruijie(config-ap)# 11nasupport enable radio 2 Ruijie(config-ap)# 11gsupport enable radio 1 Ruijie(config-ap)# 11ngsupport enable radio 1 Ruijie(config-ap)# 11acsupport enable radio 1 Ruijie(config-ap)# no 11bsupport enable radio 1 Ruijie(config-ap)# coverage-area-control 20 Ruijie(config-ap)# response-rssi 20 radio 1 Ruijie(config-ap)# response-rssi 20 radio 2 Ruijie(config-ap)# assoc-rssi 15 radio 1 Ruijie(config-ap)# assoc-rssi 15 radio 2
Verification	● Run **show running** to check whether the 2.4 GHz or 5 GHz network is enabled or disabled.
AC	Ruijie(config)# show running !

	ac-controller sta-limit 1024 no capwap dtls enable 802.11b network disable country CN country US !
	● Run **show ap-config running** *ap-name* to display the STA access control parameters for AP1.
AC	Ruijie(config)# show ap-config running AP1 ! ap-config 220em no 11bsupport enable radio 1 coverage-area-control 20 response-rssi 20 radio 1 response-rssi 20 radio 2 assoc-rssi 15 radio 1 assoc-rssi 15 radio 2 radio-type 1 802.11b radio-type 2 802.11a !

4.4.2 Configuring AP RF Parameters

Configuration Effect

- Configure the RF parameters for APs and radios for easier configuration management.

Configuration Steps

↘ Enabling A-MPDU

- Optional.
- On an AC, enable A-MPDU for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to enable A-MPDU.

Command	**802.11n a-mpdu enable radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with A-MPDU. The value ranges from 1 to 96.

Defaults	By default, A-MPDU is enabled.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration takes effect only when the AP radios operate in 802.11n or 802.11ac mode. The configuration is supported only by certain APs.

Configuring the Maximum 802.11n MCS Index Value

- Optional.
- On an AC, configure the maximum 802.11n MCS index value for specified AP. Then the AC delivers the configuration to the APs to inform the APs of the maximum 802.11n MCS index value.

Command	**802.11n mcs support** *num* **radio** *radio-id*
Parameter Description	*num*: specifies the MCS index value, which ranges from 0 to 23. *radio-id*: specifies the IDs of the radios assigned with the maximum 802.11n MCS index value. The value ranges from 1 to 96.
Defaults	By default, the maximum 802.11n MCS index value is 23.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration takes effect only when the AP radios operate in 802.11n or 802.11ac mode.

Configuring the Maximum 802.11ac MCS Index Value

- Optional.
- On an AC, configure the maximum 802.11ac MCS index value for specified AP. Then the AC delivers the configuration to the APs to inform the APs of the maximum 802.11ac MCS index value.

Command	**802.11ac mcs support** *num* **radio** *radio-id*
Parameter Description	*num*: specifies the MCS index value, which ranges from 0 to 96. *radio-id*: specifies the IDs of the radios assigned with the maximum 802.11ac MCS index value. The value ranges from 1 to 48.
Defaults	By default, the maximum 802.11n MCS index value is 29.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration takes effect only when the AP radios operate in 802.11ac mode.

Configuring the Maximum 802.11ax MCS Index Value

- Optional.

- On an AC, configure the maximum 802.11ax MCS index value for specified AP. Then the AC delivers the configuration to the APs to inform the APs of the maximum 802.11ax MCS index value.

Command	**802.11ax mcs support** *num* **radio** *radio-id*
Parameter Description	*num*: specifies the MCS index value, which ranges from 0 to 95. *radio-id*: specifies the IDs of the radios assigned with the maximum 802.11ac MCS index value. The value ranges from 1 to 96.
Defaults	By default, the maximum 802.11n MCS index value is 95.
Command Mode	AP configuration mode
Configuration Usage Guide	1. The configuration takes effect only when the AP radios operate in 802.11ax mode. 2. Number of spatial streams = Maximum MCS index value/12 +1. For example, if the maximum MCS index value is 31, the maximum number of spatial streams is 3.

Configuring the Antenna Transmit/Receive Type

- Optional.
- On an AC, configure the antenna transmit/receive type for specified APs. Then the AC assigns the settings to the APs to instruct the APs to use the specified antenna selection masks to send and receive packets.

Command	**antenna** { **transmit** | **receive** } *value* **radio** *radio-id*
Parameter Description	**transmit**: is the antenna transmit parameter. **receive**: is the antenna receive parameter. *value*: specifies the antenna selection mask. The value ranges from 1 to 7. *radio-id*: specifies the IDs of the radios assigned with the antenna transmit/receive type. The value ranges from 1 to 96.
Defaults	In AP configuration mode, the default antenna selection mask varies with different product models and antenna quantities and is determined based on the product model. By default, no antenna transmit/receive type is configured in AP group configuration mode.
Command Mode	AP configuration mode or AP group configuration mode
Configuration Usage Guide	The configuration takes effect only when the AP radios operate in 802.11n or 802.11ac mode.

Configuring Usage of External Antennas for APs

- Optional.
- On an AC, configure usage of external antennas for specified APs. Then the AC assigns the settings to the APs to instruct the APs to enable external antennas and disable internal antennas.

Command	**external-antenna enable radio** *radio-id*

Parameter Description	*radio-id*: specifies the IDs of the radios enabled with external antenna usage. The value ranges from 1 to 96.
Defaults	By default, usage of internal antennas is enabled, and usage external antennas is disabled.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Configuring Omnidirectional Antennas or Directional Antennas

- Optional.
- After this command is configured, the AC delivers the configuration to an AP to notify the AP of the antenna to be used.

Command	**antenna type { omnidirection | direction } [radio** *radio-id*]
Parameter Description	**omnidirection**: Specifies an omnidirectional antenna. **direction**: Specifies a directional antenna. *radio-id*: Specifies the ID of a radio. The value ranges from **1** to **96**.
Defaults	An omnidirectional antenna is used by default.
Command Mode	AP configuration mode, all-AP configuration mode, and AP group configuration mode
Usage Guide	1. This configuration is valid only to radios supporting both omnidirectional antennas and directional antennas. 2. If the internal antennas and external antennas can be switched, the configuration of internal and external antennas takes effect prior to that of omnidirectional and directional antennas. 3. When no radio is specified, the configuration takes effect on all radios of an AP. 4. The **antenna type omnidirection** and **antenna type direction radio** *radio-id* commands cannot be simultaneously configured for a specific AP/AP group/all APs; otherwise, the later configuration overwrites the previous configuration.

Configuring the Beacon Frame Transmission Period

- Optional.
- On an AC, configure the beacon frame transmission period for specified APs. Then the AC assigns the settings to the APs to instruct the APs to transmit beacon frames according to the configured period.

Command	**beacon period** *milliseconds* **radio** *radio-id*
Parameter Description	*milliseconds*: specifies the beacon frame transmission period. The value ranges from 20 to 1000, in the unit of ms. *radio-id*: specifies the IDs of the radios assigned with the beacon frame transmission period. The value ranges from 1 to 96.
Defaults	By default, the beacon frame transmission period is 100 ms.

Command Mode	AP configuration mode
Configuration Usage Guide	The configuration is supported only by certain APs.

Configuring Bandwidth Assignments

- Optional.
- On an AC, configure bandwidth assignments for specified APs. Then the AC assigns the settings to the APs to instruct the APs to switch the channel bandwidth to the specified bandwidth.

Command	**chan-width** { **20** | **40 | 80 | 160** } **radio** {*radio-id* | [*802.11b* | *802.11a*]}
Parameter Description	**20**: specifies the 20 MHz bandwidth. **40**: specifies the 40 MHz bandwidth. **80**: specifies the 80 MHz bandwidth. **160**: Specifies the **160** MHz bandwidth. *radio-id*: specifies the IDs of the radios assigned with bandwidth. The value ranges from 1 to 96. **802.11b**: indicates that bandwidth is assigned to all the radios in 2.4 GHz. **802.11a**: indicates that bandwidth is assigned to all the radios in 5.8 GHz.
Defaults	The default channel bandwidth of 5.8G radio on 802.11ax new products is 40 Mbps. The default channel bandwidth of the other radio is 20 Mbps.
Command Mode	AP configuration mode
Configuration Usage Guide	If you select **802.11b**, the bandwidth is configured for all the radios in 2.4 GHz. The settings take effect when the APs go online for the first time and are automatically applied to the radios. If you select **802.11a**, the condition is the same for the radios in 5.8 GHz. The bandwidth configuration takes effect only when APs operate in 802.11n or 802.11ac mode.

Configuring Channel Assignments

- Optional.
- On an AC, configure channel assignments for specified APs. Then the AC assigns the settings to the APs to instruct the AP radios to operate in specified channels.

Command	**channel** *channel-id* **radio** *radio-id* | **802.11b | 802.11a** }
Parameter Description	*channel-id*: specifies the operating channels of AP radios. *radio-id*: specifies the IDs of the radios assigned with channels. The value ranges from 1 to 96. **802.11b**: indicates that bandwidth is assigned to all the radios in 2.4 GHz. **802.11a**: indicates that bandwidth is assigned to all the radios in 5.8 GHz.
Defaults	The radio resource management (RRM) system automatically adjusts channels. By default, no channel assignments are configured.
Command Mode	AP configuration mode

Configuration Usage Guide	The configuration is supported only by certain APs.

Configuring the Country Code Set Supported by an AC

- Optional.
- Add a country code to the country code set supported by an AC before you configure AP radios to use the country code.

Command	**country** *country-code*
Parameter Description	*country-code*: specifies the country code to be added.
Defaults	The country code set supported by the AC is {"CN"}.
Command Mode	AC configuration mode
Configuration Usage Guide	The country code "CN" supported by the AC cannot be deleted.

Configuring a Country Code

- Optional.
- Ensure that the configured country code is in the country code set supported by an AC. The AC will assign the settings to the APs to instruct the APs to use the configured country code.

Command	**country** *country-code* **radio** {*radio-id* | [*802.11b* | *802.11a*]}
Parameter Description	*country-code*: specifies the country code to be added. *radio-id*: specifies the IDs of the radios assigned with the country code. The value ranges from 1 to 48. *802.11b*: indicates that the country code is assigned to all the radios in 2.4 GHz. *802.11a*: indicates that the country code is assigned to all the radios in 5.8 GHz.
Defaults	The country code used by APs is "CN".
Command Mode	AP configuration mode
Configuration Usage Guide	1. The country code "CN" supported by the AC cannot be deleted. 2. The configuration is supported only by certain APs. 3. Before you configure APs, determine the country code set supported by the AC. If the country code used by an AP is changed, the RF band, channel, and power for the AP are also changed. 4. If you select **802.11b**, the country code is configured for all the radios in 2.4 GHz. The settings take effect when the APs go online for the first time and are automatically applied to the radios. If you select **802.11a**, the condition is the same for the radios in 5.8 GHz. 5. 2.4 GHz radios do not support channel 14.

Configuring the Country Code Set Supported by an AC

- Optional.
- Add a country code to the country code set supported by an AC before you configure AP radios to use the country code.

Command	**country-code** *country-code*
Parameter Description	*country-code*: specifies the country code to be added.
Defaults	The country code set supported by the AC is CN.
Command Mode	AP configuration mode
Configuration Usage Guide	The country code "CN" supported by the AC cannot be deleted. The following country codes are available for choice:

Code	Country
AE	United Arab Emirates
AM	Armenia
AR	Argentina
AT	Austria
AU	Australia
AZ	Azerbaijan
BE	Belgium
BG	Bulgaria
BH	Bahrain
BN	Brunei Darussalam
BO	Bolvia
BR	Brazil
BY	Belarus
BZ	Belize
CA	Canada
CH	Switzerland
CL	Chile
CN	China
CO	Colombia
CR	Costa Rica
CY	Cyprus
CZ	Czech Republic
DE	Germany
DK	Denmark
DO	Dominican Republic
EC	Ecuador
EE	Estonia

EG	Egypt
ES	Spain
FI	Finland
FR	France
GB	United Kingdom
GE	Georgia
GR	Greece
GT	Guatemala
HK	Hong Kong
HN	Honduras
HR	Croatia
HU	Hungary
ID	Indonesia
IE	Ireland
IL	Israel
IN	India
IQ	Iraq
IR	Iran
IS	Iceland
IT	Italy
JO	Jordan
JP	Japan
KP	North Korea
KR	Korea ROC
KW	Kuwait
KZ	Kazakhstan
LB	Lebanon
LI	Liechtenstein
LK	Sri Lanka
LT	Lithuania
LU	Luxembourg
LV	Latvia
MA	Morocco

RU	Russia
SA	Saudi Arabia
SE	Sweden
SG	Singapore
SI	Slovenia
SK	Slovak Republic
SV	El Salvador
SY	Syria
TH	Thailand
TN	Tunisia
TR	Turkey
TT	Trinidad & Tobago
TW	Taiwan
UA	Ukraine
US	United States
UY	Uruguay
UZ	Uzbekistan
VE	Venezuela
VN	Vietnam
YE	Yemen
ZA	South Africa
ZW	Zimbabwe

Enabling Radios

- Optional.
- Enable radios on an AC. Then the AC assigns the settings to the APs to instruct the APs to enable the corresponding radios.

Command	**enable-radio** { *radio-id* | **all** }
Parameter Description	*radio-id*: specifies the IDs of the radios to be enabled. The value ranges from 1 to 96. **all**: indicates that all radios are enabled.
Defaults	By default, radios are enabled.
Command Mode	AP configuration mode
Configuration Usage Guide	When radios are enabled or disabled, the wireless STAs connected to the radios will go offline. The configuration is supported only by certain APs.

Configuring the Fragmentation Threshold

- Optional.
- On an AC, configure the fragmentation threshold for specified APs. Then the AC assigns the settings to the APs to instruct the AP radios to perform fragment logic processing according to the configured threshold.

Command	**fragment-threshold** *value* **radio** *radio-id*
Parameter Description	*value*: specifies the fragmentation threshold, which must be an even number ranging from 256 to 2346. *radio-id*: specifies the IDs of the radios assigned with the fragmentation threshold. The value ranges from 1 to 96.
Defaults	The default fragmentation threshold is 2346 bytes.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration is supported only by certain APs.

Enabling the Protection Mode

- Optional.
- On an AC, enable the protection mode for specified APs. Then the AC assigns the settings to the APs to instruct the AP radios to enable the protection mode.

Command	**green-field enable radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with the protection mode. The value ranges from 1 to 96.
Defaults	By default, the protection mode is disabled.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration takes effect only when the AP radios operate in 2.4 GHz.

Configuring the Transmit Power

- Optional.
- On an AC, configure the transmit power for specified APs. Then the AC assigns the settings to the APs to instruct the AP radios to use the transmit power.

Command	**power local** *power***radio** {*radio-id* | [*802.11b* | *802.11a*]}
Parameter Description	*power*: specifies the percent of transmit power for APs. The value ranges from 1 to 100. *radio-id*: specifies the IDs of the radios assigned with the transmit power. The value ranges from 1 to 96. *802.11b*: indicates that the transmit power is assigned to all the radios in 2.4 GHz. *802.11a*: indicates that the transmit power is assigned to all the radios in 5.8 GHz.
Defaults	The RRM system automatically adjusts the transmit power. By default, no transmit power is configured.
Command Mode	AP configuration mode or AP group configuration mode
Configuration Usage Guide	If you select **802.11b**, the transmit power is configured for all the radios in 2.4 GHz. The settings take effect when the APs go online for the first time and are automatically applied to the radios. If you select **802.11a**, the condition is the same for the radios in 5.8 GHz. The configuration is supported only by certain APs.

Configuring a Frequency Band

- Optional.
- After a frequency band is assigned to AP radios, the RRM module analyzes the operating channel of the AP radios in global mode, adjusts the channel, and assigns the optimal channel to the AP. The AP radios are instructed to operate in the specified channel.

Command	**radio-type** *radio-id* { **802.11a** | **802.11b** }
Parameter Description	*radio-id*: specifies the IDs of the radios assigned with the frequency band. The value ranges from 1 to 96. **802.11a**: specifies the 5 GHz operating band. **802.11b**: specifies the 2.4 GHz operating band.
Defaults	A single-band AP (radio 1) supports the 2.4 GHz frequency band. For a dual-band AP, radio 1 supports the 2.4 GHz frequency band, and radio 2 supports the 5 GHz frequency band.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration is supported only by certain APs.

Configuring the RTS Threshold

- Optional.
- On an AC, configure the RTS threshold for specified APs. Then the AC assigns the settings to the APs to instruct the AP radios to use the configured threshold.

Command	**rts-threshold** *value* **radio** *radio-id*
Parameter Description	*value*: specifies the value of the RTS threshold. The value ranges from 257 to 2347, in the unit of bytes. *radio-id*: specifies the IDs of the radios assigned with the RTS threshold. The value ranges from 1 to 96.

Defaults	The default RTS threshold is 2347.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Enabling Short GI

- Optional.
- On an AC, enable short GI for specified APs. Then the AC assigns the settings to the APs to instruct the AP radios to use short GI.

Command	**short-gi enable radio** *radio-id* **chan-width** { **20** | **40** | **80** |**160** }
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with short GI. The value ranges from 1 to 96. **20**: specifies the 20 MHz bandwidth. **40**: specifies the 40 MHz bandwidth. **80**: specifies the 80 MHz bandwidth. **160**: specifies the 160 MHz bandwidth.
Defaults	By default, 20Mbps, and 40Mbps at 2.4GHz radio are enabled. 20Mbps, 40Mbps, 80Mbps and 160Mbps at 5.8GHz radio are enabled.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Configuring the Preamble Type

- Optional.
- On an AC, configure the preamble type for specified APs. Then the AC assigns the settings to the APs to instruct the AP radios to use the configured preamble type.

Command	**preamble** { **long** | **short** } **radio** *radio-id*
Parameter Description	**long**: indicates that APs transmit only the frames with long preambles. **short**: indicates that APs can transmit the frames with short or long preambles. *radio-id*: specifies the IDs of the radios assigned with the preamble type. The value ranges from 1 to 96.
Defaults	By default, the short preamble type is supported.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration is supported only by certain APs.

Configuring the Short Slot Time

- Optional.
- On an AC, configure the short slot time for specified APs. Then the AC assigns the settings to the APs to instruct the AP radios to enable the short slot time feature.

Command	**short-slot-time radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios assigned with the short slot time. The value ranges from 1 to 96.
Defaults	By default, the short slot time function is enabled.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Enabling TSC Update

- Optional.
- On an AC, enable TSC update for specified APs. Then the AC assigns the settings to the APs to instruct the AP to enable TSC update.

Command	**update-key-tsc enable**
Parameter Description	N/A
Defaults	By default, TSC update is disabled.
Command Mode	AP configuration mode or AP group configuration mode
Configuration Usage Guide	N/A

Configuring the Maximum Distance of Wireless Transmission Between APs and the Peer End

- Optional.
- On an AC, configure the maximum distance of wireless transmission between APs and the peer end for specified APs. Then the AC assigns the settings to the APs to instruct the AP radios to send and receive packets according to the maximum distance.

Command	**peer-distance** *val* **radio** *radio-id*
Parameter Description	*val*: specifies the maximum wireless transmission distance allowed by APs. The value ranges from 1000 to 25000, in the unit of m. *radio-id*: specifies the IDs of the radios assigned with the maximum wireless transmission distance. The value ranges from 1 to 96.

Defaults	By default, the maximum wireless transmission distance is 1000 m.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration is supported only by certain APs.Perform the configuration only when the actual maximum distance of wireless transmission between APs and the peer end is greater than 1000 m. You can set the distance to a large value but do not set it to a value smaller than the actual distance.

Configure MIMO for Multi Users

- Optional.
- After this command is configured, the AC will deliver the configuration to the AP to enable the MU-MIMO function on the AP.

Command	**mu-mimo enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the radio ID, in the range from 1 to 96.
Defaults	If the radio does not support the mu-mimo function, the AC does not support it by default. If the radio supports the mu-mimo function and it is enabled on the AP by default, it is enabled on the AC by default. If the radio supports the mu-mimo function and it is disabled on the AP by default, it is disabled on the AC by default.
Command Mode	AP configuration mode all-AP configuration mode AP group configuration mode
Configuration Usage Guide	N/A

Enabling the OFDMA Function for a Radio

- Optional.
- After this command is configured, 802.11ax STAs can transmit data by using OFDMA.

Command	**ofdma enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio. The value ranges from **1** to **96**.
Defaults	OFDMA is enabled by default.
Command Mode	AP configuration mode, all-AP configuration mode, and AP group configuration mode
Usage Guide	N/A

Configuring Radio Parameters(Power, Channel, Antenna Type)

- Optional.
- After this command is configured,, the AC will change the radio type or optimize the power, channel, antenna configuration and deliver the configuration to the AP.

Command	**radio-optimize** [{ **802.11a** | **802.11b** } { **802.11a** | **802.11b** }]
Parameter Description	**802.11a**: specifies the 5 GHz operating band. **802.11b**: specifies the 2.4 GHz operating band.
Defaults	This function is disabled by default.
Command Mode	AP configuration mode
Configuration Usage Guide	This command cannot be configured in all-AP configuration mode. If the target AP is offline, you can optimize the radio configuration but cannot change the radio type. If you want to change the radio type, please run the **radio-type** command. The optimized configuration will be saved and take effect next time when the AP goes online. If the target AP is online, you can optimize the radio configuration and change the radio type. You can also optimize the current radio configuration without changing the radio type. If the AP does not support this function, radio configuration will not be changed. If the AP supports this function, radio configuration will be optimized immediately and this command will be saved.

Configuring Channel Switching

- Optional.
- After this command is configured, the AC will switch the two channels on the same radio.

Command	**channel-switch** *radio-id1 radio-id2*
Parameter Description	*radio-id1*: Specifies the first radio ID. *radio-id2*: Specifies the second radio ID.
Defaults	Mcell function is disabled by default.
Command Mode	AP configuration mode
Configuration Usage Guide	This command cannot be configured in all-AP configuration mode. This command cannot be configured for offline APs. This command must be configured after the third radio is enabled for user access. This command is not saved. After configuration, the channels are switched and then saved.

Enabling mcell Function

- Optional.
- After this command is configured, the AP reception sensitivity will be reduced.

Command	**mcell enable radio** *radio-id*
Parameter Description	*radio-id*: specifies the radio ID, in the range from 1 to 96.
Defaults	Mcell function is disabled by default.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Verification

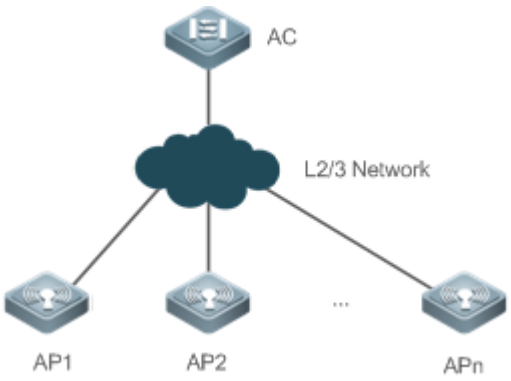
- Run **show ap-config running** *ap-name* to display the parameter settings of STA access control.

Configuration Example

Configuring AP RF Parameters

Scenario

Figure 4-4



In Figure 4-4 an AC is connected to fit APs. On the AC, configure the RF parameters for AP1 according to the following steps:

1. Set the global country code to CNCN.
2. Configure support for CN on the AC.
3. Enable A-MPDU for radio 1 of AP1.
4. Set the maximum 802.11n MCS index value to 15 for radio 1 of AP1.
5. Set the maximum 802.11ac MCS index value to 19 for radio 1 of AP1.
6. Set the maximum 802.11ax MCS index value to 21 for radio 2 of AP1.
7. Set the antenna selection masks of the transmit type and receive type to 7 and 5 respectively for radio 1 of AP1.
8. Enable usage of external antennas and disable usage of internal antennas for radio 1 of AP1.
9. Enable directional antenna on AP1.
10. Set the beacon frame transmission period to 200 ms for radio 1 of AP1.
11. Configure the "CN" country code for radio 1 of AP1.
12. Assign channel 11 to radio 1 of AP1.
13. Assign the 20 MHz bandwidth to radio 1 of AP1.
14. Enable short GI for radio 1 of AP1 in 20 MHz.
15. Enable the protection mode for radio 1 of AP1.
16. Configure 3.2us guard interval for 802.11ax packets on radio2 of AP1.
17. Configure the short preamble type for radio 1 of AP1.
18. Configure the short slot time for radio 1 of AP1.
19. Assign channel 149 to radio 2 of AP1.
20. Assign the 40 MHz bandwidth to radio 2 of AP1.
21. Enable radio 2 of AP1.
22. Set the fragmentation threshold to 2346 bytes for radio 2 of AP1.
23. Set the percent of transmit power to 100% for radio 2 of AP1.
24. Set the RTS threshold to 2347 bytes for radio 2 of AP1.
25. Enables TSC update for AP1.

	26. Set the maximum distance of wireless transmission between APs and the peer end to 3000 m for radio 1 of AP1. 27. Enable MU-MIMO onAP1 Radio 2
	28. Set the maximum distance of wireless transmission between APs and the peer end to 3000mradio 1 of AP1. 29. Enable MU-MIMO for radio 2 of AP1. 30. Enable ofdma for radio 2 of AP1.
Configuration Steps	● On the AC, configure the RF parameters for AP1.

4.4.3 Configuring Data Rate Control Parameters

Configuration Effect

- Configure the data rate control parameters for fit APs centrally for easier configuration management.

Configuration Steps

Configuring the Data Rate Set Supported by 802.11a STAs

- Optional.
- On an AC, configure the data rate set supported by 802.11a STAs. Then the AC assigns the settings to all the APs to instruct the APs to apply the configured data rate set to 802.11a STAs.

Command	**802.11a network rate** { **6** | **9** | **12** | **18** | **24** | **36** | **48** | **54** } { **disabled** | **mandatory** | **supported** }
Parameter Description	**6**: specifies the 6 Mbps data rate. **9**: specifies the 9 Mbps data rate. **12**: specifies the 12 Mbps data rate. **18**: specifies the 18 Mbps data rate. **24**: specifies the 24 Mbps data rate. **36**: specifies the 36 Mbps data rate. **48**: specifies the 48 Mbps data rate. **54**: specifies the 54 Mbps data rate. **disabled**: indicates that the data rate set is not supported. **mandatory**: indicates that support for the data rate set is mandatory. **supported**: indicates that support for the data rate set is optional.
Defaults	Support for the 6 Mbps, 12 Mbps, and 24 Mbps data rates is mandatory, whereas support for the 9 Mbps, 18 Mbps, 36 Mbps, 48 Mbps, and 54 Mbps data rates is optional.
Command Mode	AC configuration mode/AP configuration mode/AP group configuration mode
Configuration Usage Guide	N/A

Configuring the Data Rate Set Supported by 802.11b STAs

- Optional.
- On an AC, configure the data rate set supported by 802.11b STAs. Then the AC assigns the settings to all the APs to instruct the APs to apply the configured data rate set to 802.11b STAs.

Command	**802.11b network rate** { **1** | **2** | **5** | **11** } { **disabled** | **mandatory** | **supported**}
Parameter Description	**1**: specifies the 1 Mbps data rate. **2**: specifies the 2 Mbps data rate. **5**: specifies the 5.5 Mbps data rate. **11**: specifies the 11 Mbps data rate.

	disabled: indicates that the data rate set is not supported. **mandatory**: indicates that support for the data rate set is mandatory. **supported**: indicates that support for the data rate set is optional.
Defaults	Support for the 1 Mbps, 2 Mbps, 5.5 Mbps, and 11 Mbps data rates is mandatory.
Command Mode	AC configuration mode/AP configuration mode/AP group configuration mode
Configuration Usage Guide	N/A

Configuring the Data Rate Set Supported by 802.11g STAs

- Optional.
- On an AC, configure the data rate set supported by 802.11g STAs. Then the AC assigns the settings to all the APs to instruct the APs to apply the configured data rate set to 802.11g STAs.

Command	**802.11g network rate** { **1** | **2** | **5** | **6** | **9** | **11** | **12** | **18** | **24** | **36** | **48** | **54** } { **disabled** | **mandatory** | **supported**}
Parameter Description	**1**: specifies the 1 Mbps data rate. **2**: specifies the 2 Mbps data rate. **5**: specifies the 5.5 Mbps data rate. **6**: specifies the 6 Mbps data rate. **9**: specifies the 9 Mbps data rate. **11**: specifies the 11 Mbps data rate. **12**: specifies the 12 Mbps data rate. **18**: specifies the 18 Mbps data rate. **24**: specifies the 24 Mbps data rate. **36**: specifies the 36 Mbps data rate. **48**: specifies the 48 Mbps data rate. **54**: specifies the 54 Mbps data rate. **disabled**: indicates that the data rate set is not supported. **mandatory**: indicates that support for the data rate set is mandatory. **supported**: indicates that support for the data rate set is optional.
Defaults	Support for the 1 Mbps, 2 Mbps, 5.5 Mbps, and 11 Mbps data rates is mandatory, whereas support for the 6 Mbps, 9 Mbps, 12 Mbps, 18 Mbps, 24 Mbps, 36 Mbps, 48 Mbps, and 54 Mbps data rates is optional.
Command Mode	AC configuration mode/AP configuration mode/AP group configuration mode
Configuration Usage Guide	N/A

Configuring the Multicast Rate

- Optional.

- On an AC, configure the multicast rate for a WLAN. Then the AC assigns the settings to all the APs on the WLAN to instruct the APs to apply the configured multicast rate within the range of the WLAN.

Command	**mcast-rate** *mcas-num*
Parameter Description	*mcast-num*: specifies the WLAN multicast rate. The 1 Mbps, 6 Mbps, 11 Mbps, 24 Mbps, and 54 Mbps options are available.
Defaults	The default multicast rate is 24 Mbps.
Command Mode	WLAN configuration mode
Configuration Usage Guide	N/A

Configuring the Beacon Frame Transmission Rate

- Optional.
- On an AC, configure the beacon frame transmission rate for specified APs. Then the AC assigns the settings to the APs to instruct the APs to transmit beacon frames according to the configured rate.

Command	**beacon rate** *rate-Mbps* **radio** {*radio-id* | [*802.11b* | *802.11a*]}
Parameter Description	*rate_Mbps*: specifies the rate at which beacon frames are transmitted. *radio-id*: specifies the IDs of the radios assigned with the beacon frame transmission rate. The value ranges from 1 to 96. *802.11b*: indicates that the beacon frame transmission rate is assigned to all the radios in 2.4 GHz. *802.11a*: indicates that the beacon frame transmission rate is assigned to all the radios in 5.8 GHz.
Defaults	By default, no beacon frame transmission rate is configured.
Command Mode	AP configuration mode
Configuration Usage Guide	1. Do not configure a beacon frame transmission rate that is disabled in the data rate set settings. 2. Because the 1 Mbps, 2 Mbps, 5.5 Mbps, and 11 Mbps rates are not supported in 5 GHz, do not set the beacon frame transmission rate to any of the preceding values for the radios in 5 GHz. 3. If you select **802.11b**, the beacon frame transmission rate is configured for all the radios in 2.4 GHz. The settings take effect when the APs go online for the first time and are automatically applied to the radios. If you select **802.11a**, the condition is the same for the radios in 5.8 GHz.

Verification

- Run **show running** to display the parameter settings of data rate control.

Configuration Example

Configuring Data Rate Control Parameters

Scenario **Figure 4-5**	 In Figure 4-5, an AC is connected to fit APs. On the AC, configure the data rate control parameters according to the following steps: 1. Disable the 6 Mbps rate for 802.11a STAs. 2. Disable the 1 Mbps, 2 Mbps, and 5.5 Mbps rates for 802.11b STAs. 3. Disable the 1 Mbps, 2 Mbps, and 5.5 Mbps rates for 802.11g STAs. 4. Set the multicast rate for WLAN1 to 54 Mbps.
	On the AC, configure the data rate control parameters for AP1 according to the following step: 1. Configure the beacon frame transmission rate for radio 1 of AP1.
Configuration Steps	● On the AC, configure the data rate control parameters.
	`Ruijie# configure terminal` `Ruijie(config)# ac-controller` `Ruijie(config-ac)# 802.11a network rate 6 disabled` `Ruijie(config-ac)# 802.11b network rate 1 disabled` `Ruijie(config-ac)# 802.11b network rate 2 disabled` `Ruijie(config-ac)# 802.11b network rate 5 disabled` `Ruijie(config-ac)# 802.11g network rate 1 disabled` `Ruijie(config-ac)# 802.11g network rate 2 disabled` `Ruijie(config-ac)# 802.11g network rate 5 disabled` `Ruijie(config-ac)# exit` `Ruijie(config)# wlan-config 1` `Ruijie(config-wlan)# mcast-rate 54`
	● On the AC, configure the beacon frame transmission rate for AP1.

	Ruijie# configure terminal Ruijie(config)# ap-config AP1 Ruijie(config-ap)# beacon rate 12.0 radio 1
Verification	● Run **show running-config** to display the parameter settings of data rate control.
	Ruijie# show running-config ... ! wlan-config 1 ss enable-broad-ssid mcast-rate 54 ! ... ! ac-controller country CN 802.11g network rate 1 disabled 802.11g network rate 2 disabled 802.11g network rate 5 disabled 802.11g network rate 11 mandatory 802.11g network rate 6 supported 802.11g network rate 9 supported 802.11g network rate 12 supported 802.11g network rate 18 supported 802.11g network rate 24 supported 802.11g network rate 36 supported 802.11g network rate 48 supported 802.11g network rate 54 supported 802.11b network rate 1 disabled 802.11b network rate 2 disabled 802.11b network rate 5 disabled

	802.11b network rate 11 mandatory 802.11a network rate 6 disabled 802.11a network rate 9 supported 802.11a network rate 12 mandatory 802.11a network rate 18 supported 802.11a network rate 24 mandatory 802.11a network rate 36 supported 802.11a network rate 48 supported 802.11a network rate 54 supported ! ...
	● Run **show ap-config running** *ap-name* to display the beacon frame transmission rate settings of AP1.
	Ruijie(config)# show ap-config running AP1 ! ap-config AP1 channel 11 radio 1 channel 149 radio 2 beacon period 200 radio 1 beacon rate 12.0 radio 1 power local 100 radio 2 !

4.4.4 Configuring Power-Save Parameters

Configuration Effect

- Configure the power-save parameters for fit APs centrally for easier configuration management.

Configuration Steps

↘ Configuring the DTIM Period

- Optional.
- The power saving effect is improved if the DTIM period is set to a large value, but the delay for downstream multicast packets is increased.

Command	**beacon dtim-period** *period-num* **radio** *radio-id*
Parameter Description	*period-num*: specifies the DTIM period. The value ranges from 1 to 255. The unit is expressed as the period of one beacon frame. *radio-id*: specifies the IDs of the radios assigned with the DTIM period. The value ranges from 1 to 96.
Defaults	The unit of the DTIM period is expressed as the period of one beacon frame.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Enabling or Disabling U-APSD Power Saving

- Optional.
- Enable U-APSD power saving to reduce the delay of the services with high real-time requirements during the power management process. The transmission of radio signals can be disabled during most of the time to extends the battery life.

Command	**apsd** { **enable | disable** } **radio** *radio-id*
Parameter Description	**enable**: enables U-APSD power saving. **disable**: disables U-APSD power saving. *radio-id*: specifies the IDs of the radios enabled with U-APSD power saving. The value ranges from 1 to 96.
Defaults	By default, U-APSD power saving is enabled.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Verification

- Run **show ap-config running** *ap-name* to display the power-save parameter settings.

Configuration Example

Configuring Power-Save Parameters

Scenario **Figure 4-6**	Configuration Steps	● On the AC, set the DTIM period to 3 for radio 1 of AP1. ● On the AC, enable U-APSD power saving for radio 1 of AP1.
	Ruijie#configure terminal Ruijie(config)#ap-config AP0001 Ruijie(config-ap)#beacon dtim-period 3 radio 1 Ruijie(config-ap)#apsd enable radio 1
Verification	● Run **show ap-config running** *ap-name* to display the power-save parameter settings of AP1.
	Ruijie(config)# show ap-config running AP1 ! ap-config AP1 802.11n mcs support 15 radio 1 802.11n mcs support 15 radio 2 update-key-tsc enable short-gi enable radio 1 chan-width 20 green-field enable radio 1 station-role root-ap radio 1 station-role root-ap radio 2 chan-width 40 radio 2 antenna receive 5 radio 1 channel 11 radio 1 channel 149 radio 2 beacon period 200 radio 1

	beacon dtim-period 3 radio 1 power local 100 radio 2 !

4.4.5 Enabling Link Integrity Detection

Configuration Effect

- Enable link integrity detection.

Configuration Steps

Enabling Link Integrity Detection

- (Mandatory) Run **link-check enable** to enable link integrity detection.

Command	**link-check enable**
Parameter Description	N/A
Defaults	By default, link integrity detection is disabled.
Command Mode	Global configuration mode
Configuration Usage Guide	By default, link integrity detection is disabled.

Verification

- Run **show running-config** to display the configuration status of link integrity detection.

Configuration Example

Enabling Link Integrity Detection

Scenario **Figure 4-7**	 In Figure 4-7, an AC is connected to fit APs. Enable link integrity detection according to the following step: 1. Enable link integrity detection.
Configuration Steps	● Enable link integrity detection on the AC.
	`Ruijie# configure terminal` `Ruijie(config)# link-check enable`
Verification	● Run **show running-config** to display the configuration status of link integrity detection.
	`Ruijie(config)# show running-config` `.....` `link-check enable` `.....`

4.4.6 Configuring E-Bag Parameters

Configuration Effect

- Configure the E-bag parameters for APs and radios for easier configuration management.

Configuration Steps

↘ Configuring the A-MPDU Software Retransmission Times

- Optional.

- On an AC, configure the A-MPDU software retransmission times for specified APs. Then the AC assigns the settings to the APs to instruct the APs to transmit A-MPDU packets according to the configured times.
- The greater the retransmission times, the lower the probability of sub-frame loss. If packets are retransmitted frequently, the burden on the air interface is increased, which affects the real-time transmission of packets on the air interface. You can increase the retransmission times if you need to avoid packet loss when there is a high probability of sub-frame loss.

Command	**ampdu-retries** *times* **radio** *radio-id*
Parameter Description	*times*: specifies the A-MPDU software retransmission times. The value ranges from 1 to 10. *radio-id*: specifies the IDs of the radios assigned with the A-MPDU software retransmission times. The value ranges from 1 to 96.
Defaults	By default, the A-MPDU software retransmission times is 10.
Command Mode	AP configuration mode
Configuration Usage Guide	The configuration takes effect only when the AP radios operate in 802.11n or 802.11ac mode. The configuration is supported only by certain APs.

Enabling or Disabling RTS Protection for A-MPDU Packets

- Optional.
- On an AC, enable RTS protection for A-MPDU packets for specified APs. Then the AC assigns the settings to the APs to instruct the APs to transmit A-MPDU packets using RTS protection.
- Enable RTS protection only when the resource waste on the air interface caused by hidden nodes is greater than the resource consumption of RTS interaction on the air interface.

Command	**ampdu-rts radio** {*radio-id* | [*802.11b* | *802.11a*]}
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with RTS protection. The value ranges from 1 to 96. *802.11b*: indicates that RTS protection is enabled for all the radios in 2.4 GHz. *802.11a*: indicates that RTS protection is enabled for all the radios in 5.8 GHz.
Defaults	By default, RTS protection for A-PMDU packets is disabled.
Command Mode	AP configuration mode
Configuration Usage Guide	If you select **802.11b**, RTS protection for A-PMDU packets is enabled for all the radios in 2.4 GHz. The settings take effect when the APs go online for the first time and are automatically applied to the radios. If you select **802.11a**, the condition is the same for the radios in 5.8 GHz. The configuration takes effect only when the AP radios operate in 802.11n or 802.11ac mode.

Configuring the Single-Time Received Ethernet Packet Quantity for APs

- Optional.
- By default, the single-time received Ethernet packet quantity varies with different APs.
- On an AC, configure the single-time received Ethernet packet quantity for specified APs. Then the AC assigns the settings to the APs to instruct the APs to limit the number of Ethernet packets received at a single time according to the settings.

Increasing Ethernet packet reception can improve network performance but may reduce APs' ability to handle key packets in real time. You can reduce Ethernet packet reception when the requirements for performance are not high but user concurrency and real-time packet handling are demanded. In this case, it is recommended that the single-time received Ethernet packet quantity be set to 25.

Command	**eth-schd** *limit*
Parameter Description	*limit*: specifies the number of Ethernet packets received at a single time. The value ranges from 1 to 256.
Defaults	By default, the single-time received Ethernet packet quantity varies with different APs.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Enabling or Disabling LDPC

- Optional.
- On an AC, enable LDPC for specified APs. Then the AC assigns the settings to the APs to instruct the APs to send and receive packets using LDPC.
- LDPC improves the coding reliability and gains. It also greatly reduces the probability of information loss during transmission in frequencies with serious noise interference. However, a small number of STAs are not compatible with LDPC, and enabling LDPC will result in packet loss.

Command	**ldpc radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with LDPC. The value ranges from 1 to 96.
Defaults	By default, LDPC is enabled.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Enabling or Disabling Transmit/Receive STBC

- Optional.
- On an AC, enable transmit/receive STBC for specified APs. Then the AC assigns the settings to the APs to instruct the APs to send and receive packets using STBC.
- STBC improves the reliability of data transmission. Some STAs may not be compatible with STBC.

Command	**stbc radio** *radio-id*
Parameter Description	*radio-id*: specifies the IDs of the radios enabled with STBC. The value ranges from 1 to 96.

Defaults	By default, STBC is enabled.
Command Mode	AP configuration mode
Configuration Usage Guide	N/A

Configuring E-bag Network Optimization in One-Click Mode

- Optional.
- Run **ebag** in AP configuration mode to quickly configure E-bag network optimization in one-click mode.
- The AP320, AP330, and AP3220 are optimized in the following aspects:

- Packet handling optimization on wired ports: **eth-schd 25**
- Optimization of wireless aggregate packet retransmission: **ampdu-retries 2**
- WiFox is disabled.

- The AP530 is optimized in the following aspects:

- By default, radios 1 and 2 use the sta-idle-time 1800 settings.
- Radio 1 optimization: The 1 Mbps, 2 Mbps, and 5.5 Mbps mandatory rates are disabled for 802.11b/g STAs, and the 11 Mbps and 24 Mbps rates are configured as mandatory rates for 802.11g STAs. RTS protection for A-MPDU packets is enabled.

- On an AC, configure E-bag network optimization for specified APs. Then the AC assigns the settings to the APs to instruct the APs to send and receive packets according to the settings.

Command	**ebag**
Parameter Description	N/A
Defaults	No default settings are available.
Command Mode	AP configuration mode
Configuration Usage Guide	Use this command only when E-bag is configured. If E-bag is not configured, do not use this command unless necessary.

Verification

- Run **show ap-config running** *ap-name* to display the E-bag parameter settings.

Configuration Example

Configuring E-Bag Parameters

Scenario **Figure 4-8**	 In Figure 4-8, an AC is connected to APs. On the AC, configure the E-bag parameters for AP1 according to the following steps: 1. Set the A-MPDU software retransmission times to 3 for radio 1 of AP1. 2. Enable RTS protection for A-MPDU packets for radio 1 of AP1. 3. Set the single-time received Ethernet packet quantity to 100 for AP1. 4. Disable LDPC for radio 1 of AP1. 5. Disable transmit/receive STBC for radio 1 of AP1.
Configuration Steps	● On the AC, configure the RF parameters for AP1.
	`Ruijie# configure terminal` `Ruijie(config)# ap-config AP1` `Ruijie(config-ap)# ampdu-retries 3 radio 1` `Ruijie(config-ap)# ampdu-rts radio 1` `Ruijie(config-ap)# eth-schd 100` `Ruijie(config-ap)# no ldpc radio 1` `Ruijie(config-ap)# no stbc radio 1`
Verification	● Run **show ap-config running** *ap-name* to display the E-bag parameter settings of AP1.
	`Ruijie(config)# show ap-config running AP1` `!` `ap-config AP1` ` ap-mac 00d0.f801.0528` `channel 11 radio 1` ` no 11acsupport enable radio 2`

Configuring E-bag Network Optimization in One-Click Mode

Scenario **Figure 4-9**	 In Figure 4-9, an AC is connected to fit APs. AP1 is configured with E-bag settings. On the AC, configure E-bag network optimization for AP1 in one-click mode.
Configuration Steps	● On the AC, configure E-bag network optimization for AP1 in one-click mode.
	Ruijie# configure terminal Ruijie(config)# ap-config AP1 Ruijie(config-ap)# ebag
Verification	● Run **show ap-config running** *ap-name* to display the E-bag parameter settings of AP1.
	Ruijie(config)# show ap-config running AP1 ! ap-config AP1 ap-mac 00d0.f801.0528

4.4.7 Configuring WLANs in One-Click Mode

Configuration Effect

- Configure WLANs quickly on devices with zero configurations in one-click mode. The one-click WLAN configuration feature helps the land survey personnel improve operation efficiency and the channel personnel execute performance tests conveniently.

Configuration Steps

↘ Configuring WLANs in One-Click Mode

- Optional.
- Run **autowifi** in configuration mode to configure WLANs in one-click mode, thus realizing fast configuration of wireless networks. The one-click WLAN configuration feature helps the land survey personnel improve operation efficiency and the channel personnel execute performance tests conveniently.

Command	**autowifi**
Parameter Description	N/A
Defaults	No default settings are available.
Command Mode	AC global configuration mode
Configuration Usage Guide	The one-click WLAN configuration feature allows you to perform fast configuration on devices with zero configurations. The one-click WLAN configuration feature helps the land survey personnel improve operation efficiency and the channel personnel execute performance tests conveniently.

Verification

- Run **show running** to display the one-click WLAN configuration.

Configuration Example

Configuring WLANs in One-Click Mode

Scenario **Figure 4-10**	 In Figure 4-10, an AC is connected to fit APs. Configure WLANs in one-click mode on the AC.
Configuration Steps	● Configure WLANs in one-click mode on the AC.
	`Ruijie# configure terminal` `Ruijie(config)# autowifi`
Verification	● Run **show running** to display the one-click WLAN configuration.
	`Ruijie(config)# show running` `!` `wlan-config 1 autowifi_1234` `!` `ap-group default` ` interface-mapping 1 2 ap-wlan-id 1` `!` `ap-config all` ` fair-schedule` `!` `ac-controller` ` 802.11g network rate 1 mandatory` ` 802.11g network rate 2 mandatory`

4.4.8 Managing the Operating Frequency Band When Power Supply Is Insufficient

Configuration Effect

When the AP power supply mode is negotiated to 15.4 W, the AP can work only in 2.4 GHz or 5 GHz. This configuration enables the AP to switch the operating frequency band (2.4 GHz or 5 GHz).

Notes

- None

Configuration Steps

- Optional.

- After this command is configured, the AC delivers the configuration to an AP to notify the AP of the operating frequency band when power supply is insufficient.

Command	**hap-poe enable radio** { **802.11a** | **802.11b** }
Parameter Description	**802.11a**: Indicates the 5 GHz band. **802.11b**: Indicates the 2.4 GHz band.
Defaults	The operating frequency band is selected based on the AP capability value by default.
Command Mode	AP configuration mode, AP group configuration mode, and all-AP configuration mode
Usage Guide	

Verification

Run the **show ap-config running** *ap-name* command to display configurations in AP configuration mode and run the **show running** command to display configurations in AP group configuration mode and all-AP configuration mode.

Configuration Example

Switching to 5 GHz When AP Power Supply Is Insufficient

Configuration Steps

The following example switches the operating frequency band to 5 GHz on the AC when power supply to AP1 is insufficient.

```
Ruijie# configure terminal
Ruijie(config)# ap-config AP1
Ruijie(config-ap)# hap-poe enable radio 802.11a
```

Verification

Run the **show ap-config running** *ap-name* command to display configuration of a specific AP.

```
Ruijie(config)# show ap-config running AP1
!
ap-config AP1
 ap-mac 00d0.f801.0528
 hap-poe enable radio 802.11a
!
```

4.5 Monitoring

Displaying

Description	Command
Displays the link information of wireless STAs.	**linktest**
Displays the AP list that maps the 802.11a or 802.11b network on an AC.	**show ac-config** { **802.11a** | **802.11b** } **summary**
Displays the antenna feeder status of all APs.	**show antenna all**
Displays the antenna feeder status of an AP.	**show antenna single** *ap-name*
Displays the radio information of all APs.	**show ap-config radio**
Displays the radio information of an AP.	**show ap-config radio ap-name** *ap-name*
Displays the configuration information of an AP radio.	**show ap-config radio** *radio-id* **config** *ap-name*
Displays the status information of an AP radio.	**show ap-config radio** *radio-id* **status** *ap-name*
Displays the radio list of an AP.	**show ap-config radio status** *ap-name*
Displays the radio information of all APs.	**show ap-config summary radio**
Displays the STA information mapped to a MAC address.	**show client details** *sta-mac*

5 Configuring WLAN WBS FWD

5.1 Overview

WLAN Basic Service-Forward Mode (WBS-FWD) is used to control the forwarding mode of packets on access points (APs). Ruijie access controllers (ACs) and APs build communications through the Control and Provisioning of Wireless Access Points (CAPWAP) channel. The AP forwards data packets in one of the following modes:

- Centralized forwarding mode: An AP encapsulates received wireless data into 802.3 frames, and sends the packets through the CAPWAP channel to the AC, which forwards the packets. When an AC receives the data packets, it sends the packets through the CAPWAP channel to the AP, which transforms the format of the packets into 802.11 frame format and sends them to the STAs.
- Local forwarding mode: An AP encapsulates received wireless data into 802.3 frames and performs Layer-2/Layer-3 forwarding, namely, the packets will be forwarded directly by the AP.

You can configure the forwarding mode for all the APs on the entire wireless local area network (WLAN), or you can specify the forwarding mode for a specified virtual local area network (VLAN), IP address, or a packet of a certain type. You can configure the AP forwarding mode based on different scenarios such as the AP load and centralized management, so that packets of different types are forwarded as required.

5.2 Applications

Application	Description
Centralized Forwarding Mode	All branch APs are managed by an AC and all packets are forwarded by the AC.
Local Forwarding Mode	All branch APs are managed by an AC, and the packets are forwarded by the AP locally.

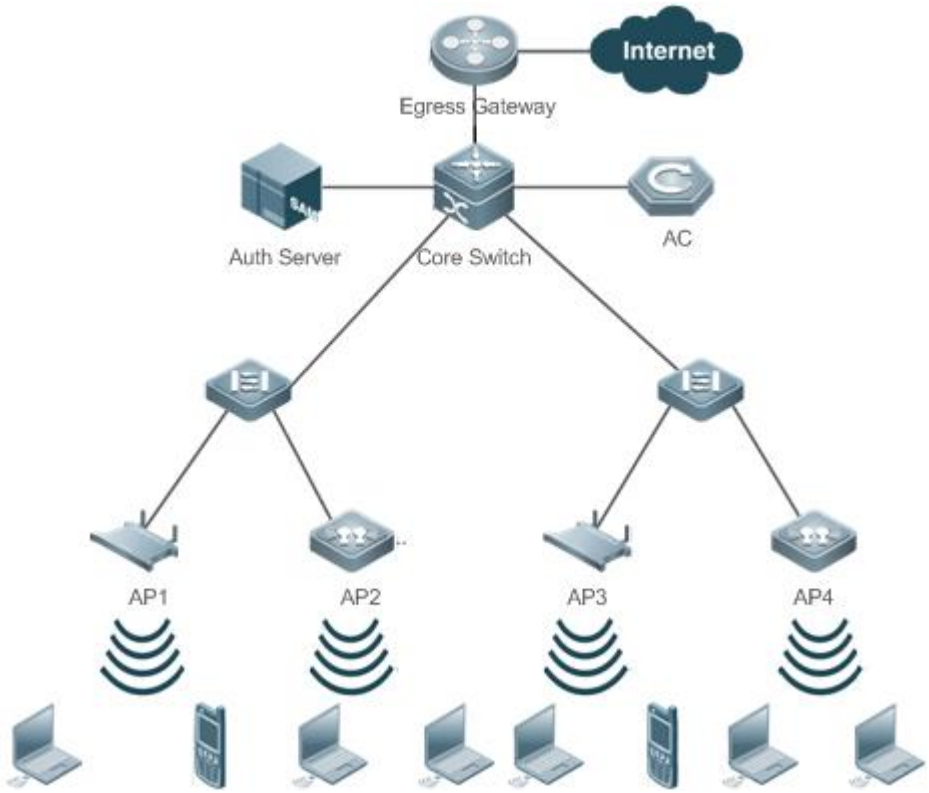
5.2.1 Centralized Forwarding Mode

Scenario

Centralized forwarding mode is applied to the following scenarios:

- All APs and the AC are within the same VLAN with sufficient bandwidth.
- The AC has high forwarding performance.
- The network egress is unified.

Figure 5-1



Deployment

- On the AC, configure centralized forwarding mode for APs.

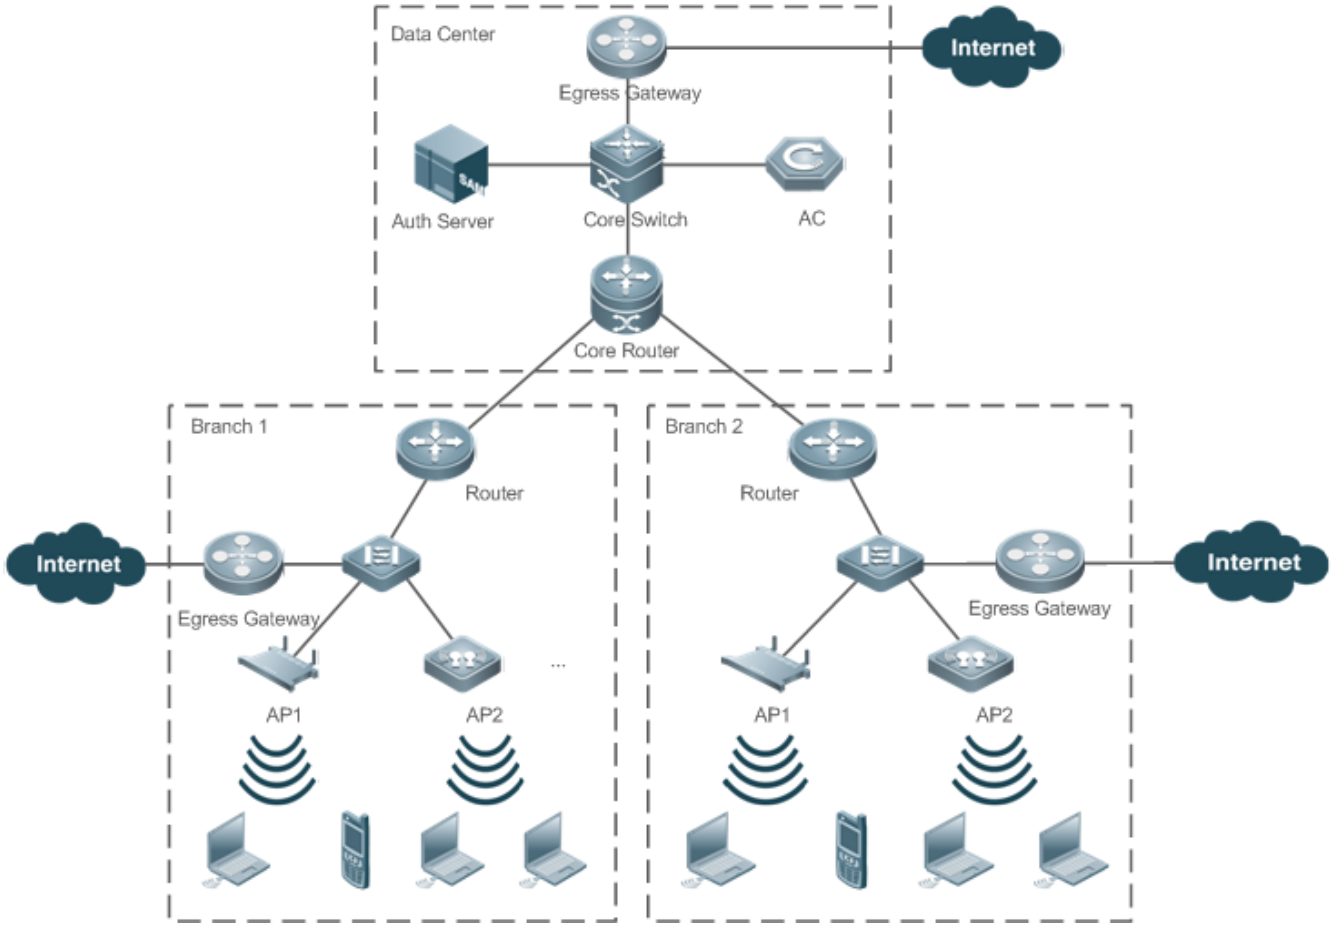
5.2.2 Local Forwarding Mode

Scenario

Local forwarding mode is applied to the following scenarios:

- APs are deployed in different branches and are managed by the AC in the headquarters.
- The bandwidth of the links between branches and the headquarter is low.
- Each branch has an independent egress.

Figure 5-2



Deployment

- On the AC, configure local forwarding mode for APs.
- On the AC, configure centralized forwarding mode for Dynamic Host Configuration Protocol (DHCP).

5.3 Features

Basic Concepts

Centralized Forwarding Mode and Local Forwarding Mode

Ruijie ACs and APs build communications through the CAPWAP channel. The AP forwards data packets in one of the following modes:

- Centralized forwarding mode: An AP encapsulates received wireless data into 802.3 frames, and sends the packets through the CAPWAP channel to the AC, which forwards the packets. When an AC receives the data packets, it sends the packets through the CAPWAP channel to the AP, which transforms the format of the packets into 802.11 frame format

and sends them to the STAs. In this case, packets are forwarded by an AC, which is convenient for centralized control and maintenance on the AC. On the other hand, it will burden the AC and require higher performance of the AC.

- Local forwarding mode: An AP encapsulates received wireless data into 802.3 frames and performs Layer-2/Layer-3 forwarding, namely, the packets will be forwarded directly by the AP. This mode poses little burden on the AC but cannot achieve centralized control and maintenance.

Comparison between the Two Forwarding Modes:

Forwarding Mode	Advantage	Disadvantage	Scenario
Centralized forwarding mode	Centralized control and maintenance on an AC; flexible service expansion	High requirement for AC performance	High AC performance, high bandwidth of links between APs and AC, few APs under an AC, and flexible service
Local forwarding mode	Low requirement for AC performance	No centralized control and maintenance	Low AC performance, low bandwidth of links between APs and AC, and many APs under an AC

Overview

Feature	Description
Configuring the Forwarding Mode of an AP	Specifies the forwarding mode of different packets on an AP.
Configuring the Forwarding Mode of an AC	Specifies the forwarding mode of different packets on an AC.

5.3.1 Configuring the Forwarding Mode of an AP

You can configure the AP forwarding mode based on different scenarios such as the AP load and centralized management, so that packets of different types are forwarded as required.

Working Principle

Forwarding Mode

There are two kinds of forwarding modes, namely, centralized forwarding mode and local forwarding mode. When an AP receives a wireless packet, it forwards the packet based on the configured mode.

You can configure the packet forwarding mode for an AP on an AC.

Configuring a Forwarding Mode

Ruijie products support the following forwarding modes:

- WLAN-based forwarding mode: Forwards the packets on all APs based on the forwarding mode (centralized forwarding mode or local forwarding mode) specified for the WLAN.

- VLAN-based forwarding mode: Forwards the packets on APs within a specified VLAN of a WLAN based on the forwarding mode (centralized forwarding mode or local forwarding mode) specified for the VLAN.
- IP-based forwarding mode: Forwards the packets of a specified destination IP address in local forwarding mode.
- DHCP-based centralized forwarding mode: Forwards all DHCP packets in centralized forwarding mode. If this function is enabled, all DHCP packets will be sent in centralized forwarding mode.

Priorities of Different Forwarding Modes

Ruijie products support the preceding four forwarding modes. These modes can be configured at the same time and their priorities are ranked as follows (in descending order):

1. DHCP-based centralized forwarding mode
2. IP-based forwarding mode
3. VLAN-based forwarding mode
4. WLAN-based forwarding mode

After a wireless packet is received by an AP, the packet will be forwarded based on the priority of the forwarding mode. If a mode of high priority is detected, the packet will be forwarded in this mode; if not, the packet will be forwarded in the default centralized forwarding mode.

For example:

1. If DHCP forwarding mode is configured, all the DHCP packets will be forwarded in centralized mode.
2. For a non-DHCP packet, if its IP address is specified for local forwarding, the packet will be forwarded in local forwarding mode. If not, Step 3 will be performed.
3. If the VLAN where the packet belongs is configured with a forwarding mode, the packet will be forwarded in this mode. If not, Step 4 will be performed.
4. If the WLAN where the packet belongs is configured with a forwarding mode, the packet will be forwarded in this mode. If not, Step 5 will be performed.
5. The packet will be forwarded in the default centralized forwarding mode.

5.3.2 Configuring the Forwarding Mode of an AC

You can configure the forwarding mode for an AC based on the load of the entire wireless network, unified management requirement, and the actual service environment. The AC adjusts, based on the configured forwarding mode, internal parameters to better adapt to the current service environment.

Working Principle

Forwarding Mode

There are hybrid forwarding mode and local forwarding mode. In AC hybrid forwarding mode, WLANs support both the centralized forwarding mode and local forwarding mode, that is, some WLANs use centralized forwarding while other WLANs

use local forwarding. In AC local forwarding mode, WLANs support only local forwarding mode (including local authentication forwarding mode).

Forwarding Mode Settings

You can configure the forwarding mode for an AC.

5.4 Configuration

Configuration	Description and Command	
Configuring WLAN-based Forwarding Mode	(Mandatory) It is used to specify the forwarding mode for the entire WLAN.	
	tunnel	Specifies the forwarding mode for the entire WLAN.
Configuring VLAN-based Forwarding Mode	(Optional) Specifies the forwarding mode for a specified VLAN of a WLAN.	
	tunnel local wlan	Specifies local forwarding as the forwarding mode for a specified VLAN of a WLAN.
	tunnel 8023 wlan	Specifies centralized forwarding as the forwarding mode for a specified VLAN of a WLAN.
Configuring IP-based Forwarding Mode	(Optional) It is used to specify local forwarding as the forwarding mode for a specified IP address.	
	local fw ip	Forwards all packets of a specified IP address in local forwarding mode.
Configuring DHCP-based Forwarding Mode	(Optional) It is used to specify centralized forwarding as the forwarding mode for DHCP packets.	
	central dhcp enable	Forwards all DHCP packets in a WLAN in centralized forwarding mode.
Configuring AC Forwarding Mode	(Optional) It is used to specify AC forwarding mode.	
	tunnel-mode	Specifies the AC forwarding mode

5.4.1 Configuring WLAN-based Forwarding Mode

Configuration Effect

- Specify a forwarding mode for the entire WLAN, including local forwarding mode, centralized forwarding mode, and local authentication forwarding mode.

Notes

- The **tunnel local-auth** command takes effect only when remote intelligent perception technology (RIPT) is enabled.

Configuration Steps

- Mandatory.
- In WLAN configuration mode on an AC, configure the forwarding mode for the entire WLAN as local forwarding mode, centralized forwarding mode, or local authentication forwarding mode.
- The default forwarding mode is centralized forwarding.
- Configure the forwarding mode before applying the WLAN template to a specified AP group. Otherwise, the configuration will not take effect.

Command	**tunnel** { **8023** | **local** | **local-auth** }
Parameter Description	**8023**: An AP encapsulates received wireless data into a 802.3 frame and forwards the packet to an AC. **local**: An AP forwards packets locally. **local-auth**: Indicates local forwarding mode. An AP forwards packets locally, and STAs are authenticated on the AP.
Defaults	The default forwarding mode is centralized forwarding.
Command Mode	WLAN configuration mode
Usage Guide	The **local-auth** command takes effect only when RIPT is enabled.

Verification

- Verify the WLAN configuration.

Configuration Example

Configuring the Forwarding Mode for All Packets in a WLAN

Scenario **Figure 5-3**	
	• With low bandwidth, WLAN 1 contains AP 1, AP 2 and AP 3 for the access of mobile phones. WLAN 1 is configured with centralized forwarding mode. • With high bandwidth. WLAN 2 contains AP 4, AP 5, and AP 6 for the access of PCs. WLAN 2 is configured with local forwarding mode.
Configuration Steps	• Enter WLAN configuration mode. • Configure the forwarding mode of the WLAN.
WLAN1	`Ruijie(config)#wlan-config 1` `Ruijie(config-wlan)#tunnel local`
WLAN2	`Ruijie(config)#wlan-config 2` `Ruijie(config-wlan)#tunnel 8023`
Verification	N/A

5.4.2 Configuring VLAN-based Forwarding Mode

Configuration Effect

- Specify the forwarding mode for a specified VLAN of a WLAN.

Notes

- You can specify the forwarding mode for the entire WLAN in WLAN-based forwarding mode, or you can specify the forwarding mode for a specified VLAN of the WLAN in VLAN-based forwarding mode.
- As VLAN-based forwarding mode prevails over WLAN-based forwarding mode, if both of these modes are configured, the packets in the specified VLAN will be forwarded in VLAN-based forwarding mode, and the others will be forwarded in WLAN-based forwarding mode.
- Configure either local forwarding or centralized forwarding for a VLAN. The two cannot be both configured.
- The VLAN can be an interface-based VLAN, MAC-based VLAN, or authentication-based VLAN.

Configuration Steps

↘ Configuring the Forwarding Mode of a WLAN

- (Optional) If the forwarding mode of a specified VLAN of a WLAN is different from the other VLANs, specify a forwarding mode for this VLAN.
- The default forwarding mode is the same as the WLAN-based forwarding mode.
- In AP group configuration mode on an AC, run **tunnel local wlan** [*wlan-id*] **vlan** [*vlan-id*] to specify local forwarding mode for a specified VLAN.

- In AP group configuration mode on an AC, run **tunnel 8023 wlan** [*wlan-id*] **vlan** [*vlan-id*] to specify centralized forwarding mode for a specified VLAN.

Command	**tunnel local wlan** [*wlan-id*] **vlan** [*vlan-id*]
Parameter Description	*wlan-id*: Indicates the WLAN. The WLAN must have been created. The value ranges from 1 to 4,094. *vlan-id*: Indicates the VLAN. The VLAN must have been created. The value ranges from 1 to 4,094.
Defaults	By default, no VLAN is specified. The forwarding mode is the same as that configured by the **tunnel** command.
Command Mode	ap-group configuration mode
Usage Guide	In WLAN configuration mode, you can run the **tunnel 8023** command to specify centralized forwarding mode for the entire WLAN, or you can run **tunnel local wlan** to specify local forwarding mode for a specified VLAN on the WLAN.

Command	**tunnel 8023 wlan** [*wlan-id*] **vlan** [*vlan-id*]
Parameter Description	*wlan-id*: Indicates the WLAN. The WLAN must have been created. The value ranges from 1 to 4,094. *vlan-id*: Indicates the VLAN. The VLAN must have been created. The value ranges from 1 to 4,094.
Defaults	By default, no VLAN is specified. The forwarding mode is the same as that configured by the **tunnel** command.
Command Mode	ap-group configuration mode
Usage Guide	In WLAN configuration mode, you can run the **tunnel local** command to specify local forwarding mode for the entire WLAN, or you can run the **tunnel local wlan** command to specify centralized forwarding mode for a specified VLAN.

Configuration Example

Configuring the Forwarding Mode of a Specified VLAN on a WLAN

Scenario **Figure 5-4**	

	 ● WLAN 1 contains AP 1, AP 2 and AP 3 which belong to VLAN 1, VLAN 2 and VLAN 3 respectively. Among them, VLAN1 and VLAN 3 are used for the access of mobile phones while VLAN 2 for PCs which require high bandwidth. Therefore, WLAN 1 is configured with centralized forwarding mode while VLAN 2 is configured with local forwarding mode. ● WLAN 2 contains AP 4, AP 5 and AP 6 which belong to VLAN 1, VLAN 2 and VLAN 3 respectively. Among them, VLAN1 and VLAN 2 are used for the access of PCs while VLAN 3 for mobile phones which require low bandwidth. Therefore, WLAN 2 is configured with local forwarding mode while VLAN 3 is configured with centralized forwarding mode.
Configuration Steps	● Enter WLAN configuration mode. ● Configure the forwarding mode of the WLAN. ● Specify a forwarding mode for the specified VLAN on the WLAN.
WLAN1	`Ruijie(config)#wlan-config 1` `Ruijie(config-wlan)#tunnel 8023` `Ruijie(config-wlan)#exit` `Ruijie(config)#ap-group default` `Ruijie(config-ap-group)#tunnel local wlan 1 vlan 2`
WLAN2	`Ruijie(config)#wlan-config 2` `Ruijie(config-wlan)#tunnel local` `Ruijie(config-wlan)#exit` `Ruijie(config)#ap-group default`

	Ruijie(config-ap-group)#tunnel 8023 wlan 2 vlan 3
Verification	N/A

5.4.3 Configuring IP-based Forwarding Mode

Configuration Effect

- Forward the packet of the specified IP address in local forwarding mode.

Notes

- You can configure the forwarding mode of an AP based on a WLAN or VLAN, or you can further configure local forwarding mode for packets of a specified IP address.
- As IP-based forwarding mode prevails over WLAN-based forwarding mode and VLAN-based forwarding mode, if all of these modes are configured, packets of a specified address will be forwarded locally, and the others will be forwarded in WLAN-based forwarding mode or VLAN-based forwarding mode.

Configuration Steps

↘ Configuring IP-based Forwarding Mode

- (Optional) You can configure local forwarding mode for packets of a specified IP address.
- In AC configuration mode on an AC, specify local forwarding for a specified IP address.
- If IP-based forwarding is not configured, packets are forwarded based on WLAN or VLAN. If IP-based forwarding is configured, packets of a specified IP address are forwarded locally.

Command	**local fw ip** [*ip address*]
Parameter Description	*ip address*: Indicates the IP address of an STA.
Defaults	By default, all IP packets are forwarded in WLAN-based forwarding mode.
Command Mode	ac-controller configuration mode
Usage Guide	IP-based forwarding is a kind of flexible forwarding mode.

Configuration Example

↘ Configuring Local Forwarding for Packets of a Specified IP Address

Scenario **Figure 5-5**	 ● WLAN 1 contains AP 1, AP 2 and AP 3 which belong to VLAN 1, VLAN 2 and VLAN 3 respectively. Among them, IP address 192.168.1.1 is used for the access of PCs while the others for mobile phones which require low bandwidth. Therefore, configure local forwarding for IP address 192.168.1.1.
Configuration Steps	● Enter AC configuration mode. ● Specify local forwarding mode for a specified IP address.
AC	`ruijie(config)#ac-controller` `ruijie(config-ac)#local fwip 192.168.1.1`
Verification	N/A

5.4.4 Configuring DHCP-based Forwarding Mode

Configuration Effect

- Forwards all DHCP packets in centralized forwarding mode.

Notes

- As DHCP-based forwarding mode prevails over WLAN-based forwarding mode, VLAN-based forwarding mode, and IP-based forwarding mode, if DHCP-based forwarding mode is configured, all the DHCP packets will be forwarded in centralized mode, and others will be forwarded as configured.
- To facilitate management of the DHCP address pool and simplify the DHCP topology, it is recommended to enable this function.

Configuration Steps

↘ **Configuring DHCP-based Forwarding Mode**

- (Optional) Perform the configuration to assign IP addresses to STAs by the AC..
- If DHCP forwarding mode is not configured, DHCP packets will be forwarded in the same way as general packets based on the forwarding mode configured. If DHCP forwarding mode is configured, DHCP packets will be forwarded in a centralized way.
- Configure the forwarding mode before applying the WLAN template to a specified AP group. Otherwise, the configuration will not take effect.

Command	**central dhcp enable**
Parameter Description	N/A
Defaults	By default, all IP packets are forwarded in WLAN-based forwarding mode.
Command Mode	WLAN configuration mode
Usage Guide	To facilitate management of the DHCP address pool and simplify the DHCP topology, it is recommended to enable this function.

Verification

- Verify the WLAN configuration.

Configuration Example

Configuring DHCP Services on an AC

Scenario **Figure 5-6**	 ● APs are deployed in different branches and are managed by the AC in the headquarters. ● The bandwidth of the links between branches and the headquarter is low. ● Each branch has an independent egress. ● IP addresses are assigned by the AC.
Configuration Steps	● Enter WLAN configuration mode. ● Configure the forwarding mode of the WLAN. ● Configure DHCP centralized forwarding mode.
AC	`ruijie(config)#wlan-config 100 ruijie_wlan` `ruijie(config-wlan)#tunnel local` `ruijie(config-wlan)#central dhcp enable`
Verification	N/A

5.4.5 Configuring AC-based Forwarding Mode

Configuration Effect

- Determine the forwarding mode of an AC: hybrid forwarding mode or local forwarding mode. In AC hybrid forwarding mode, WLANs support both the centralized forwarding mode and local forwarding mode, that is, some WLANs use centralized forwarding while other WLANs use local forwarding. In AC local forwarding mode, WLANs support only local forwarding mode (including local authentication forwarding mode).

Configuration Steps

- Optional.
- On an AC, in AC configuration mode, set the forwarding mode of the AC to hybrid forwarding or local forwarding.
- If no forwarding mode is configured for an AC, the AC uses the hybrid forwarding mode by default.
- Save the configuration and restart the device after configuration. Otherwise, the configuration does not take effect.

Command	**tunnel-mode** { **hybrid** | **local** }
Parameter Description	**hybrid**: Indicates the AC hybrid forwarding mode. In this mode, WLANs support the coexistence of centralized forwarding mode and local forwarding mode, that is, some WLANs use centralized forwarding while some WLANs adopt local forwarding. **local**: Indicates the AC local forwarding mode. In this mode, WLANs support only local forwarding mode (including local authentication forwarding mode).
Defaults	The default value is hybrid forwarding mode.
Command Mode	AC configuration mode
Usage Guide	1. The AC forwarding mode switching takes effect only after the configuration is saved and the device is restarted. Mode switching does not trigger device restart and you need to manually restart the device. 2. If the device is restarted after the AC forwarding mode configuration is added to or modified in the **config.text** file, the configuration takes effect only after the device is restarted again. It is invalid to delete the AC forwarding mode configuration from the **config.text** file. 3. The AC forwarding mode configuration is preconfigured in the system, that is, the configuration takes effect after the device is restarted even if the **write** command is not executed. 4. If the tunnel mode is set to **hybrid** for an AC, the AC is explicitly configured to adopt the hybrid forwarding mode. After configuration, the tunnel mode is unchanged when the default configuration is updated due to the AC version upgrade. 5. When an AC switches from hybrid forwarding mode to local forwarding mode, WLANs using centralized forwarding automatically switch to local forwarding mode after the device restart. 6. When an AC switches from local forwarding mode to hybrid forwarding mode, the forwarding mode of WLANs does not change automatically after the device restart. 7. In local forwarding mode, service configurations that need to be supported by centralized forwarding keep unchanged but their functions do not take effect. Such configurations include but are not limited to the broadcast forwarding proportion and token bucket configuration of the data plane, WQoS AC-based rate limit, WIDS AC-based/AC-SSID-based layer-2 isolation, and application identification.

	8. The maximum number of manageable APs and STAs changes accordingly after the AC forwarding mode is changed. 9. The AC forwarding mode does not support default configuration restoration using the reset button.

Verification

- Check the AC configurations.
- Run the **show ac-config** command to display the current effective forwarding mode of the AC.

Configuration Example

Setting the Forwarding Mode of an AC to Local Forwarding

Scenario **Figure 5-7**	 Note: ● The AC is deployed in bypass mode. All STA traffic does not need to pass through the AC. The AC is configured in local forwarding mode so as to manage more APs.
Configuration Steps	● Enter the AC configuration mode. ● Configure the forwarding mode for the AC, save the configuration, and restart the device.
	`Ruijie(config)#ac-controller` `Ruijie(config-ac)#tunnel-mode local` `Ruijie(config-ac)#end` `Ruijie#write`

	Building configuration... [OK] Ruijie#reload Reload system?(Y/N)y
Verification	N/A

5.5 Monitoring

Displaying

Description	Command
Displays the WLAN configuration.	**show wlan-config cb** *wlan-id*
Displays the AC forwarding mode	**show ac-config**

6 Configuring ETH-MNG

6.1 Overview

Wired ports of an AP include WAN ports and LAN ports. The WAN ports are used to connect to the uplink access switches, and the LAN ports exist in some AP products (wall-mounted AP series and i-Share+ AP series) and are used to access wired STAs or other devices and forward data to WAN ports. In the fit AP network architecture, an AP obtains the AC IP address over the WAN port to establish a CAPWAP tunnel, and the AP restricts AC IP address obtaining via DHCP packets over the LAN port. The LAN port cannot be used to establish a CAPWAP tunnel.

6.1.1 Protocols and Standards

- N/A

6.2 Applications

Application	Description
Configuring VLANs on LAN Ports	Configure VLANs on LAN ports to separate APs and wired users.

6.2.1 Configuring VLANs on LAN Ports

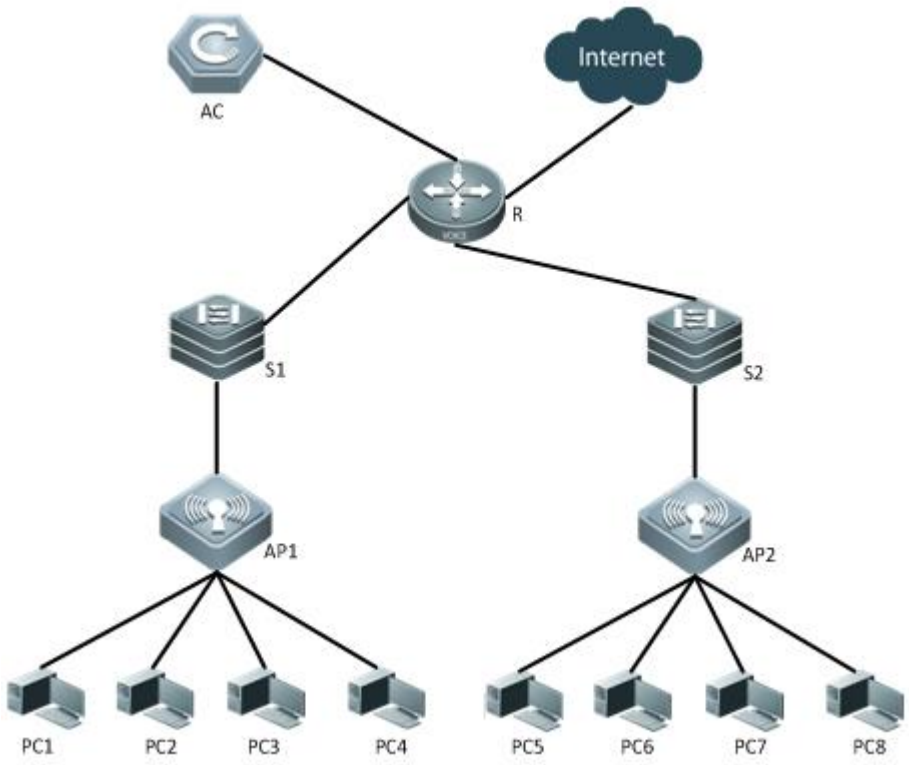
Scenario

Configure VLANs on LAN ports.

In the following figure:

- An AC is connected to the Internet through a router. Two APs (AP1 and AP2) are connected to the router through two switches, and are associated with the AC.
- PC1, PC2, PC3, and PC4 are associated with AP1; PC5, PC6, PC7, and PC8 are associated with AP2. These PCs access the Internet through the AC.

Figure 6-1



R is a network egress router.
S1 and S2 are Layer 2 (L2) switches, and serve as the access devices of the APs.
AP1 is directly connected to S1, and AP2 to S2.

Corresponding Protocols

- The L2 switches provide the access function for the APs.
- The router R is connected to the network formed by the AC and the APs. It is also connected to the PCs and the Internet.
- Configure VLANs on LAN ports.

6.3 Features

Basic Concepts

N/A

Overview

Feature	Description

VLAN Configuration of an AP	Configure the default VLAN of an AP, VLANs on wired ports, and transmission VLANs of iShare+ series.
Maximum LAN Port Bandwidth	Configure the maximum bandwidth of various LAN ports of APs so as to avoid the slow Internet access of wireless users in a scenario where wireless and wired users coexist and wired users occupy a substantial bandwidth.

6.3.1 VLAN Configuration of an AP

Working Principle

An AP automatically removes the native VLAN tag from frames to be sent to STAs. That is, in local forwarding mode, if the VLAN of an STA is the same as the native VLAN, frames sent to the STA will not carry the native VLAN tag, and the access switch determines the VLAN to which the STA belongs. The default VLAN of the AP is VLAN 1. The default VLAN of the AP, VLAN of wireless users, and VLAN of wired users can be planned flexibly to ensure that the STAs and AP are in the same VLAN or different VLANs.

iShare+ APs can be deployed in cascading mode, and the transmission VLAN can be configured to ensure that VLAN packets of downlink devices can be forwarded by uplink devices.

6.3.2 LAN port Bandwidth Restriction

Working Principle

The LAN port bandwidth restriction function is used to configure the maximum bandwidth of various LAN ports of APs so as to avoid the slow Internet access of wireless users caused in a scenario where wireless and wired users coexist and wired users occupy a substantial bandwidth.

6.4 Configuration

Configuration	Description and Command	
Configuring the Default VLAN of an AP	⚠ (Optional) It is used to configure the native VLAN of an AP.	
	ap-vlan	Configures the default VLAN of an AP.
Configuring the transmission VLAN	⚠ (Optional) It is used to configure the transmission VLAN of an AP.	
	pass-vlan	Configures the transmission VLAN of an AP.
Configuring the VLAN of AP Wired Users	⚠ (Optional) It is used to configure the VLAN of wired users when the AP provides an Ethernet interface for access of wired users.	
	wired-vlan	Configures the VLAN used by the wired network port.

Configuring the Wired Network Port Status of an AP	⚠ (Optional) It is used to disable wired network ports when the AP provides Ethernet ports for access of wired users.	
	wired-interface	Disables wired network ports of an AP.
Configuring the Sub-Interface of the WAN Interface on the AP	⚠ (Optional) It is used to configure the sub-interface of the WAN interface on the AP.	
	ap-subif	Configures the sub-interface of the WAN interface on the AP.
Configuring the Maximum Bandwidth of LAN ports	⚠ (Optional) It is used to configure the maximum bandwidth of LAN ports of APs.	
	wired-rate *value*	Configures Rate LAN ports on the AP.
Configuring Port Mode Switching of an AP	⚠ (Optional) It is used to configure port mode switching of an AP.	
	switch port-mode	Configures port mode switching of an AP.

6.4.1 Configuring the Default VLAN of an AP

Configuration Effect

The AP automatically removes the TAG from a frame that contains the native VLAN before forwarding the frame. That is, in local forwarding mode, when the VLAN of the user is the same as the native VLAN, the frame of the user does not contain the TAG when forwarded, and the access switch determines the VLAN to which the user belongs.

Notes

- After this command is executed, an online AP will go offline and then the connection will be set up again.
- When a wireless distribution system (WDS) is deployed, the same AP-VLAN must be planned for the ROOT-BRIDGE and NONROOT-BRIDGE devices; otherwise, the NONROOT-BRIDGE devices cannot share the same address pool with the ROOT-BRIDGE devices or the NONROOT-BRIDGE devices cannot even forward packets properly.
- This command needs to be configured only in the following case: In local forwarding mode, STAs and an AP belong to a same subnet and VLANs have been configured for the STAs and the AP. This command is not required in other cases.
- If the static DHCP address pool is configured, and the client ID is specified to use Bridge-Group Virtual Interface (BVI) 1, configuration of this command will change the BVI interface of the AP. In this case, the DHCP server configuration must be modified; otherwise, the address cannot be obtained.
- If the AP uses the PPPoE dial-up mode to obtain the address, the CAPWAP module on the AP will select dialer 1 as the source interface, and the STA traffic will be forwarded without containing the TAG. Therefore, this command is meaningless.

Configuration Steps

↘ Configuring the Default VLAN of an AP

- Optional.

- When planning of the users' native VLANs is required, you can configure the same VLAN as the default VLAN of an AP and the VLAN of the user. In this way, both the VLAN of the user and the VLAN of the AP are determined by the access switch.

Command	ap-vlan*vlan-id*
Parameter Description	*vlan-id*: indicates the ID of the specified VLAN. The VLAN ID ranges from 1 to 4094. The default value is 1.
Defaults	1
Command Mode	AP configuration mode or all AP (ap-config all) configuration mode
Usage Guide	The AP automatically removes the TAG from a frame that contains the native VLAN before forwarding the frame. That is, in local forwarding mode, when the VLAN of the user is the same as the native VLAN, the frame of the user does not contain the TAG when forwarded, and the access switch determines the VLAN to which the user belongs.

Verification

- Run the **show running** command to display the configurations of all APs, or the **show ap-config running** command to display the configurations of a specified AP.

Configuration Example

Setting the VLAN ID of the Native VLAN of AP1 to 20

Configuration Steps	Enter the AP configuration mode on the AC. Set the VLAN ID of the native VLAN of AP1 to 20.
AC	Ruijie(config)# ap-config AP1 Ruijie(config-ap)# ap-vlan20
Verification	Run the **show ap-config running** command to display the location information of AP1.
AC	Ruijie#show ap-config running ! ap-config AP1 ap-vlan 20 !

Common Errors

According to the planning, the native VLAN of the switch is VLAN 20, and all wireless/wired users and APs belong to VLAN 20. The following configurations are incorrect:

On the AC:

```
Ruijie(config)# ap-configAP120
Ruijie(config-ap)# wired-vlan20
Ruijie(config-ap)# exit
Ruijie(config)#wlan-config 1 ssid
Ruijie(config-wlan)#tunnel local
Ruijie(config-wlan)#exit
Ruijie(config)#ap-group default
Ruijie(config-ap-group)#interface-mapping 1 20 radio 1
```

On the switch:

```
Ruijie(config)#interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# switchport mode trunk
Ruijie(config-if-GigabitEthernet 0/1)#switchport trunk native vlan 20
```

The configurations here are incorrect because the VLAN of users is different from the native VLAN of APs. Therefore, the uplink packets of APs contain TAG 20 when forwarded, and the access switch transparently forwards VLAN 20 and assigns addresses to users. As the native VLAN of the switch is VLAN 20, the downlink packets do not contain the TAG when forwarded. The Native VLAN of APs is 1 by default. Therefore, the packets cannot be forwarded to users, and the wireless and wired users cannot obtain their addresses.

Either of the following methods can be used to modify the configurations:

Method 1: Change **wired-vlan 20** to **wired-vlan 1** and **interface-mapping 1 20 radio 1** to **interface-mapping 1 1 radio 1**, and the native VLAN of the switch remains unchanged.

Method 2: Add the native VLAN configurations for APs, and other configurations remain unchanged.

On the AC:

```
Ruijie(config)# ap-configAP120
Ruijie(config-ap)# ap-vlan 20
```

6.4.2 Configuring the Transmission VLAN for an AP

Configuration Effect

When the i-Share+ APs are cascaded or a ring network is deployed, configure the transmission VLAN for the master AP, so that STAs associated with different APs can forward packets if they are deployed in different VLANs.

Notes

The transmission VLAN cannot conflict with the VLANs specified by the **interface-mapping**, **ap-vlan**, and **wired-vlan** commands, and cannot be VLAN 2444.

Configuration Steps

Configuring the Transmission VLAN for the AP

- Optional.
- When the i-Share+ APs are cascaded or a ring network is deployed, run this command to configure the transmission VLAN, so that STAs associated with different APs can forward packets if they are deployed in different VLANs.

Command	**pass-vlan** *vlan-range*
Parameter Description	*vlan-range*: indicates the VLAN ID range. Multiple VLAN IDs can be specified. Separate two VLAN IDs by a comma (,) and separate two VLAN ID ranges by a hyphen (-).
Defaults	No VLAN is configured by default.
Command Mode	AP configuration mode
Usage Guide	1. This command can be configured for all APs but takes effect only on the i-Share+ master AP. 2. When this command is run, the transmission VLAN will be created on the i-Share+ master AP, so that the master AP can forward packets based on the transmission VLAN. In addition, the transmission VLAN will be automatically pruned on the downlink port of the master AP, to prevent broadcast and multicast packets of other master APs from being flooded to mini APs connected to the master AP.

Verification

Run the **show ap-config running** command to display the AP configuration.

Configuration Example

Configuring the Transmission VLAN of AP1 to VLAN 20

Configuration Steps	Enter the AP configuration mode of the AC. Configure the transmission VLAN of AP1 to VLAN 20.
AC	`Ruijie(config)# ap-config AP1` `Ruijie(config-ap)# pass-vlan 20`
Verification	Run the **show ap-config running** command to display transmission VLAN.
AC	`Ruijie#show ap-config running` `!` `ap-config AP1` `pass-vlan 20` `!`

Common Errors

N/A

6.4.3 Configuring the VLAN of Wired Users

Configuration Effect

Specify the VLAN of wired users when the AP provides an Ethernet interface for access of wired users.

Notes

- This command can be configured on all APs, but the configurations take effect only on APs that are equipped with the wired network ports.
- If this command does not contain the **port** parameter, the same VLAN is configured for all the wired network ports. When the same VLAN should be configured for four ports, the command without the **port** parameter is configured and displayed.
- In wireless AP mode, the AP implements only the wireless access function, but does not assign addresses to users. In this mode, if the VLAN used by the wired network port is configured the same as the VLAN of the AP, the VLAN of the packets sent over the wired network port will be determined by the access switch, instead of the VLAN specified in this command. If the packets sent over the wired network port must contain the TAG when forwarded, the native VLAN of the access switch cannot be the same as the VLAN of the wired network port; otherwise, the packets cannot be forwarded to the wired network port.
- In wireless routing mode, the AP can assign addresses to users. In this mode, wired users obtain IP addresses from the DHCP address pool, and the VLAN of the interface of the address pool must be the same as the VLAN specified in this command.
- When the configurations of the wired network port are automatically saved on the AP and the VLAN of the wired network port is different from the native VLAN of the AP, the AP cannot obtain the IP address of the LAN interface on the AP after the AP is restarted, and management cannot be implemented through the wired network port. In this case, the RESET key of the AP can be pressed and held to restore the factory settings.

Configuration Steps

↘ Configuring the Access VLAN of the AP Wired Network Port

- Optional.
- To plan VLANs so that the VLAN of a wired user is different from the VLAN of the AP, run the **wired-vlan** command on the AC.

Command	**wired-vlan** *vlan-id* [**slot** *slot-id* [**secondary**]] [**port** *port-id*] **auto-save**
Parameter Description	*vlan-id*: indicates the ID of the specified VLAN. The VLAN ID ranges from 1 to 4094. By default, the VLAN used by the wired network port is the same as the VLAN of the AP. *slot-id*: indicates the slot to which a Mini AP belongs. The value ranges from 1 to 24. **secondary**: applies to the secondary device.

	port-id: indicates the ID of the wired network port. The value ranges from 1 to 4. **auto-save**: indicates that configurations are automatically saved on the AP. After the AP is restarted, the configurations can be restored.
Defaults	By default, the VLAN used by the wired network port is not configured, indicating that this VLAN is the same as the VLAN of the AP.
Command Mode	AP configuration mode, all AP configuration mode, or AP group configuration mode
Usage Guide	The **slot** parameter takes effect only for i-Share+ APs. If no slot is specified, the configuration applies to all Mini APs. The fit AP is started without being configured, and its configurations are sent from the AC. The auto-save parameter can be configured to enable automatic saving of the wired network port configurations on the AP. In this way, when the AP is disconnected from the AC, the wired network port configurations can be restored after the AP is restarted, and users can still access the network through the wired network port.

Verification

Run the **show running** command to display the configurations of all APs, or the **show ap-config running** command to display the configurations of a specified AP.

Configuration Example

↘ Configuring VLAN 20 for the Wired Network Port of AP1

Configuration Steps	Enter the AP configuration mode on the AC. Configure VLAN 20 for the wired network port of AP1.
AC	`Ruijie(config)# ap-config AP1` `Ruijie(config-ap)# wired-vlan20`
Verification	Run the **show ap-config running** command to display the configurations of AP1.
AC	`Ruijie#show ap-config running` `!` `ap-config AP1` `wired-vlan 20` `!`

Common Errors

N/A

6.4.4 Configuring the Wired Network Port Status of an AP

Configuration Effect

Enable or disable the wired network port of an AP.

Notes

- This command can be configured on all APs, but the configurations take effect only on APs that are equipped with the wired network ports.
- If this command does not contain the **port** parameter, the same configurations are applied to all the wired network ports. When all the four ports should be disabled, the command without the **port** parameter is configured and displayed.
- After the AP wired network port is disabled and the AP is restarted, management cannot be implemented through the wired network port. In this case, you can press and hold the RESET key of the AP to restore factory settings.

Configuration Steps

↘ Configuring the Wired Network Port Status of an AP

- Optional.
- To enable or disable wired network ports of an AP, run the **wired-interface** command on the AC.

Command	**wired-interface** [**slot** *slot-id* [**secondary**]] [**port** *port-id*] **enable**
Parameter Description	*slot-id*: indicates the slot to which a Mini AP belongs. The value ranges from 1 to 24. **secondary**: applies to the secondary device. *port-id:* indicates the ID of the wired network port. The value ranges from 1 to 4. **enable**: indicates that the specified wired port is enabled.
Defaults	All the wired network ports are enabled by default.
Command Mode	AP configuration mode, all AP configuration mode, or AP group configuration mode
Usage Guide	The wired network ports of APs can be disabled when APs provide the Ethernet ports for access of wired users, but the application scenario does not require access to the wired network or deployment of the wired network is not completed yet. The **slot** parameter takes effect only for i-Share+ APs. If no slot is specified, the configuration applies to all Mini APs.

Verification

Run the **show running** command to display the configurations of all APs, or the **show ap-config running** command to display the configurations of a specified AP.

Configuration Example

Disabling All Wired Network Ports of AP1

Configuration Steps	Enter the AP configuration mode on the AC. Disable all wired network ports of AP1.
AC	Ruijie(config)# ap-config AP1 Ruijie(config-ap)# no wired-interfaceenable
Verification	Run the **show ap-config running** command to display the configurations of AP1.
AC	Ruijie#show ap-config running ! ap-config AP1 no wired-interfaceenable !

Common Errors

N/A

6.4.5 Configuring the Sub-Interface of the WAN Interface on the AP

Configuration Effect

A wireless AP creates a sub-interface of the WAN interface by default so that the STA data contains the TAG when forwarded. In wireless routing mode that AP can assign addresses to users, the users' gateway is located on the AP, and the related packets do not need to contain the TAG when forwarded. Therefore, the **ap-subif enable** command can be used to delete the sub-interface of the WAN interface on the AP to prevent an address conflict caused by the same gateway address of STAs.

Notes

If the AP obtains the address in PPPoE dial-up mode, the sub-interface of the WAN interface on the AP will be automatically deleted. In dial-up mode, this command cannot be used to configure the sub-interface of the WAN interface on the AP.

Configuration Steps

Configuring the Sub-Interface of the WAN Interface on the AP

- Optional.
- In wireless routing mode, delete the sub-interface of the WAN interface on the AP; otherwise, an address conflict occurs when a large number of packets are forwarded through the sub-interface because the gateway addresses of users are the same.

Command	**ap-subif enable**
Parameter Description	N/A
Defaults	A sub-interface of the WAN interface is created by default.
Command Mode	AP configuration mode or all AP configuration mode
Usage Guide	N/A

Verification

Run the **show running** command to display the configurations of all APs, or the **show ap-config running** command to display the configurations of a specified AP.

Configuration Example

Deleting the Sub Interface of the WAN Interface from AP1

Configuration Steps	Enter the AP configuration mode on the AC. Delete the sub-interface of the WAN interface from AP1.
AC	`Ruijie(config)# ap-config AP1` `Ruijie(config-ap)# no ap-subif enable`
Verification	Run the **show ap-config running** command to display the configurations of AP1.
AC	`Ruijie#show ap-config running` `!` `ap-config AP1` `no ap-subif enable` `!`

Common Errors

N/A

6.4.6 LAN port Bandwidth Restriction

Networking Requirements

- Configure the maximum bandwidth of various LAN ports.

Notes

- N/A

Configuration Steps

Configuring the LAN Port Bandwidth Restriction Function

- The configuration is optional.
- Perform this configuration on the AC or on a fat AP.
- Run the **wired-rate** command to configure the maximum bandwidth of various LAN ports.

Command	**wired-rate** *value* [**port** *port-id*] [**slot** *slot-id* [**secondary**]]
Parameter Description	If no port ID is specified, all ports are configured. If no slot ID is specified for an i-Share+ AP, all LAN ports on all mini APs are configured. The **slot** parameter takes effect only for i-Share+ APs. If no slot is specified, the configuration applies to all Mini APs.
Defaults	By default, the maximum bandwidths of various LAN ports are not limited.
Command Mode	AP configuration mode/AP group configuration mode
Usage Guide	N/A

Verification

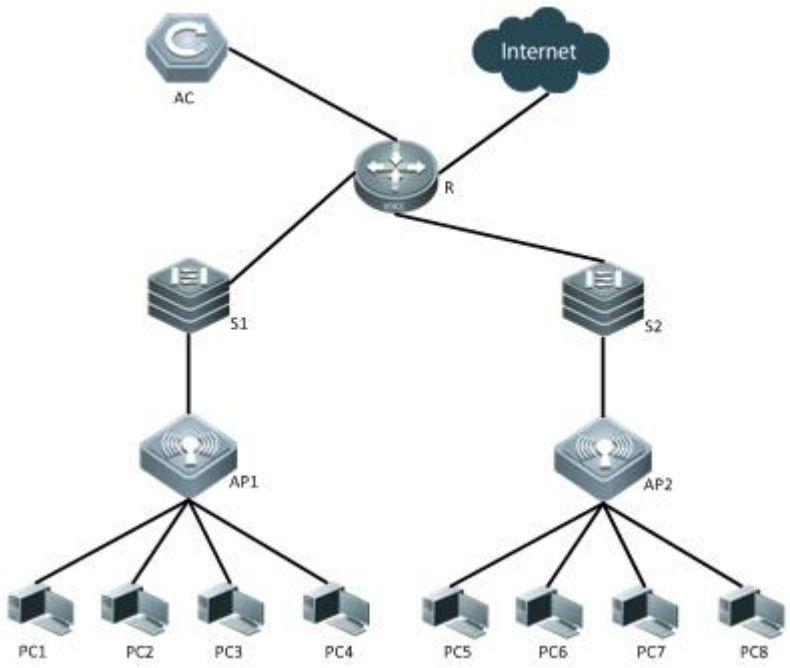
- Run the **show running-config** command to display the configuration about the bandwidth restriction of various LAN ports.

Configuration Example

Configuring LAN Port Bandwidth Restriction

Scenario

Figure 6-2



Suppose the bandwidths of the LAN ports need to be restricted in the fit AP environment, as shown in Figure 6-2.

1. Configure the maximum bandwidth of various LAN ports.

Configuration Steps	● On the AC, set the maximum bandwidth of port 3 on the AP to 30 Mbps.
AC	`Ruijie(config)# ap-config [ap-name]` `Ruijie(config-ap)# wired-rate 30 port 3` ● On the AC, set the maximum bandwidth of port 3 on the group APs to 30 Mbps. `Ruijie(config)# ap-group default` `Ruijie(config-group)#wired-rate 30 port 3` ● On the AC, set the maximum bandwidth of all LAN ports on the group APs to 30 Mbps. `Ruijie(config)# ap-group default` `Ruijie(config-group)#wired-rate 30` ● On the AC, set the maximum bandwidth of port 3 on all APs to 30 Mbps. `Ruijie(config)# ap-config all` `Ruijie(config-ap)# wired-rate 30 port 3` ● On the AC, set the maximum bandwidth of port 3 of slot 3 on the i-Share+ AP to 30 Mbps. `Ruijie(config)# ap-config am5528`

	`Ruijie(config-ap)# wired-rate 30 port 3 slot 3` ● On the AC, set the maximum bandwidth of all LAN ports of slot 3 on the i-Share+ AP to 30 Mbps. `Ruijie(config)# ap-config am5528` `Ruijie(config-ap)# wired-rate 30 slot 3`
AP120-W	● On one AP120-W, set the maximum bandwidth of FastEthernet 0/4 to 40 Mbps. `Ruijie(config)#interface fastEthernet 0/4` `Ruijie(config-if-FastEthernet 0/4)#wired-rate 40`
AP130-W	● On one AP130-W, set the maximum bandwidth of GigabitEthernet 0/4 to 40 Mbps. `Ruijie(config)#interface GigabitEthernet 0/4` `Ruijie(config-if-GigabitEthernet 0/4)#wired-rate 40`
Verification	● On the AC, run the **show ap-config running-config** command to display the configuration.
AC	`Ruijie(config)# show ap-config running-config` `ap-config ap120w-4` `wired-rate 30 port 3`
	● On the AC, run the **show running-config** command to display the configuration.
AC	`Ruijie(config)# show running-config` `ap-group default` `wired-rate 30 port 3`
	● On the AC, run the **show running-config** command to display the configuration.
AC	`Ruijie(config)# show running-config` `ap-group default` `wired-rate 30`
	● On the AC, run the **show running-config** command to display the configuration.

AC	`Ruijie(config)# show running-config` `ap-config all` ` …` ` wired-rate 30 port 3` ` …` `Ruijie(config)# show running-config` `ap-config am5528` ` …` ` wired-rate 30 port 3 slot 3` ` …` `Ruijie(config)# show running-config` `ap-config am5528` ` …` ` wired-rate 30 slot 3` ` …`
	● On the AP, run the **show running-config** command to display the configuration.
AP120-W	`Ruijie(config)# show running-config` `…` `interface FastEthernet 0/4` `wired-rate 40` `…`
AP130-W	`Ruijie(config)# show running-config` `…` `interface GigabitEthernet 0/4` `wired-rate 40` `…`

Common Errors

- N/A

6.4.7 Configuring Port Mode Switching of an AP

Configuration Effect

- The iShare+ product AM5532 can switch among the following three port modes: 4 x 1000M copper ports, 4 x 10G fiber ports, and 2 x 1000M copper ports + 2 x 10G fiber ports.

Notes

- This command takes effect only on the AM5532 and needs to be configured on the AM5532.
- After the switching command is executed, the port mode is automatically saved and the write operation does not need to be executed. However, the device needs to be restarted manually for the configuration to take effect.

Configuration Steps

↘ Configuring Port Mode Switching of an AP

- Optional.
- When the AM5532 is deployed, select the corresponding port mode and connect the network cable.

Command	**switch port-mode** { **copper** | **fiber** | **mixed** }
Parameter Description	**copper**: indicates the mode of 4 x 1000M copper ports. **fiber**: indicates the mode of 4 x 10G fiber ports. **mixed**: indicates the mode of 2 x 1000M copper ports + 2 x 10G fiber ports.
Defaults	The default value is **mixed**, that is, the mode of 2 x 1000M copper ports + 2 x 10G fiber ports.
Command Mode	Privileged EXEC mode
Usage Guide	The uplink ports of the AM5532 support three port modes, that is, 4 x 1000M copper ports, 4 x 10G fiber ports, and 2 x 1000M copper ports + 2 x 10G fiber ports. In the mode of 4 x 1000M copper ports, ports 25 to 28 are used; in the mode of 4 x 10G fiber ports, ports 29 to 32 are used; in the mode of 2 x 1000M copper ports + 2 x 10G fiber ports, ports 27, 28, 31, and 32 are used.

Verification

- Run the **show port-mode** command to display configurations.

Configuration Example

↘ Disabling All Wired Network Ports of AP1

Configuration Steps	● On the AM5532, disable all wired network ports of AP1.
AP	`Ruijie# switch port-mode fiber`
Verification	● Run the **show ap-config running** command to display configurations of AP1.
AC	`Ruijie#show port-mode` `Current port mode:  mixed` `Configure port mode:  fiber`

7 Configuring DATA-PLANE

7.1 Overview

The data plane provides broadcast forwarding control functions, including broadcast forwarding weight control and broadcast wireless forwarding control.

Broadcast forwarding weight control means restricting the weights of packet types for broadcast forwarding, so as to prevent STAs from being influenced when a certain type of packets occupy all resources.

Broadcast wireless forwarding control means forwarding only necessary packets to the wireless network, so as to prevent some useless broadcast packets from occupying substantial radio frequency (RF) resources.

- Broadcast forwarding weight control is applicable to all packets to be flooded.
- Broadcast wireless forwarding control is applicable to all packets to be sent to the radio interface.

Protocols and Standards

- N/A

7.2 Applications

Application	Description
Broadcast Forwarding Control	Set up the network with at least one AC and one fit AP.

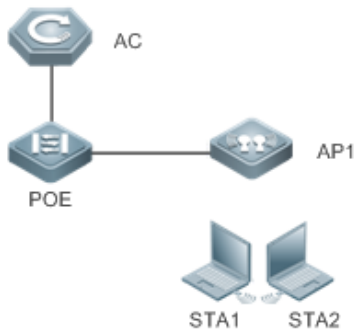
7.2.1 Broadcast Forwarding Control

Scenario

An AC is deployed in the wireless network and enabled with broadcast wireless forwarding control function.

The AC controls the wireless forwarding of broadcast packets, as shown in Figure 7-1.

Figure 7-1



AC: a wireless access controller.
PoE: a gateway switch for the AP.
AP: a wireless access point.
STA1 and STA2: user equipment used as STAs.

Corresponding Protocols

- Enable the broadcast wireless forwarding control function on the AC.

7.3 Features

Basic Concepts

Broadcast Forwarding Weight Control

A network switching device may need to flood broadcast packets, multicast packets, and some unicast packets. A weight can be set for each type of packets to prevent a certain type of broadcast packets from exhausting all broadcast forwarding capabilities, thereby improving STAs' network experience.

Broadcast Wireless Forwarding Control

The broadcast wireless forwarding control function is used to forward only necessary broadcast packets to the wireless network, so as to prevent certain broadcast packets from occupying substantial air interface resources and improve the network rates of STAs.

Overview

Feature	Description
Broadcast Forwarding Weight Control	Restricts the weights of packet types for broadcast forwarding, so as to protect RF resources from being occupied by a certain type of packets and thereby guarantee normal forwarding of other packets.
Broadcast Wireless Forwarding Control	Controls whether to forward broadcast packets to the wireless network, so as to prevent useless broadcast packets from occupying substantial RF resources.

7.3.1 Broadcast Forwarding Weight Control

Broadcast forwarding weight control is used to restrict a certain type of packets, so that the ratio of this type of packets is no greater than the specified weight during broadcast forwarding.

Working Principle

The broadcast forwarding weight control function classifies packets at first into unicast packets, multicast packets, broadcast packets, unknown multicast packets, and unknown unicast packets.

- Classify packets. Packets may be roughly classified into the following types: unicast packets, multicast packets, broadcast packets, unknown multicast packets, and unknown unicast packets.

- Allocate a token bucket to each type of packets, and record the number of packets permitted to pass at this moment.
- According to the configured broadcast forwarding weights, calculate the number of packets permitted to pass within each interval, and adjust the sizes of the token buckets accordingly.
- When a packet arrives, determine the type of the packet and check whether there is any token in the token bucket corresponding to the packet type. If the token bucket contains a token, the packet is permitted to pass; otherwise, the packet is discarded.

7.3.2 Broadcast Wireless Forwarding Control

The broadcast wireless forwarding control function is used to forward only partial packets that affect STAs to the wireless network, so as to prevent useless broadcast packets from occupying substantial air interface resources.

Working Principle

Wireless networks differ from wired networks in performance. In a wireless network, air interface resources are shared by STAs and APs which often becomes a bottleneck for STAs. Meanwhile, they are seized for a long time because broadcast packets are sent at low rates.

In practice, some broadcast packets are useless for STAs. Forwarding these packets to the wireless network will result in fewer air interface resources and worse user experience.

One solution is to classify broadcast packets for forwarding control. Only the packets of specified types are forwarded to the wireless network.

7.4 Configuration

Configuration	Description and Command	
Broadcast Forwarding Weight Control	Optional configuration. Set the weights of packet types for broadcast forwarding.	
	data-plane queue-weight	Configures the weights of packet types for broadcast forwarding on the AC or AP.
	data-plane token	Configures the refresh interval of the broadcast token bucket and bucket-based rate on the AC or AP.
Broadcast Wireless Forwarding Control	Optional configuration. Enable the broadcast wireless forwarding function.	
	data-plane wireless-broadcast	Enables or disables the broadcast wireless forwarding control function on the AC or AP.

7.4.1 Configuring Broadcast Forwarding Weights

Networking Requirements

- You can control the weight of a packet type for forwarding according to actual network conditions, so as to avoid network congestion for sudden traffic spike.

Notes

- N/A

Configuration Steps

Configuring Broadcast Forwarding Weights

- Optional configuration. Run the **data-plane queue-weight** command to configure the broadcast forwarding weights.
- For centralized forwarding, configure this command in the global configuration mode on the AC.
- For local forwarding, configuration this command in the AP configuration mode on the AC.

Command	**data-plane queue-weight** *unicast-packet-weight multicast-packet-weight broadcast-packet-weight unknown-multicast-packet-weight unknown-unicast-packet-weight*
Parameter Description	*unicast-packet-weight*: sets the forwarding weight of unicast packets. The range is from 1 to 100. The default weight is 16. *multicast-packet-weight*: sets the forwarding weight of multicast packets. The range is from 1 to 50. The default weight is 4. *broadcast-packet-weight*: sets the forwarding weight of broadcast packets. The range is from 1 to 50. The default weight is 2. *unknown-multicast-packet-weight*: sets the forwarding weight of unknown multicast packets. The range is from 1 to 25. The default weight is 1. *unknown-unicast-packet-weight*: sets the forwarding weight of unknown unicast packets. The range is from 1 to 25. The default weight is 1.
Defaults	Default weights are applied.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring Refresh Interval of Broadcast Token Bucket and Bucket-based Rate

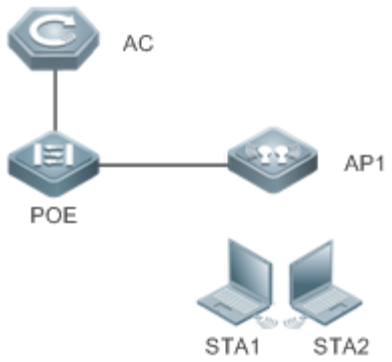
- Optional configuration. Run the **show run** command to display the configuration.
- For centralized forwarding, configure this command in the global configuration mode on the AC.
- For local forwarding, configuration this command in the AP configuration mode on the AC.

Command	**data-plane token** *token-interval token-base-rate*
Parameter Description	*token-interval*: Refresh interval of broadcast token bucket in 10ms. The default interval is 1. *token-base-rate*: Token bucket-based rate. The default rate is 64 for the AC and 5 for the AP.
Defaults	Default parameters are applied.
Command Mode	Global configuration mode
Configuration Usage	Broadcast rate per second = Packet weight × (1s/Refresh Interval) x Token bucket-based rate For example, the broadcast rate per second for the AC = 1 x (1 / 0.01) × 64 = 6400 pps

Configuration Example

Configuring Broadcast Forwarding Weights

Figure 7-2



Configuration Steps	Configure the forwarding weights of packet types for broadcast forwarding in global configuration mode.
AC/AP	`Ruijie#configure terminal` `Ruijie(config)#data-plane queue-weight 100 50 50 25 25` `Ruijie(config)#data-plane token 10 10` `Ruijie(config)#exit`
Verification	Run the **show run** command to display the configuration.

AC/AP	Ruijie#show run ... ! cwmp ! data-plane queue-weight 100 50 50 25 25 data-plane token 10 10 ! ...

Common Errors

- N/A

7.4.2 Configuring Broadcast Wireless Forwarding

Networking Requirements

- Useless broadcast packets are not forwarded to the air interface.

Notes

- N/A

Configuration Steps

↘ Broadcast Forwarding Function

- Optional configuration. By default, the broadcast wireless forwarding function is disabled. Run the data-plane wireless-broadcast command in global configuration mode to enable or disable this function.

Command	**data-plane wireless-broadcast**{ **enable** | **disable** }
Parameter Description	**enable**: permits all broadcast packets to be forwarded to the air interface **disable**: prohibits all broadcast packets from being forwarded to the air interface
Defaults	The broadcast wireless forwarding function is disabled; that is, broadcast packets are not forwarded to the wireless network.
Command Mode	Global configuration mode
Configuration Usage	N/A

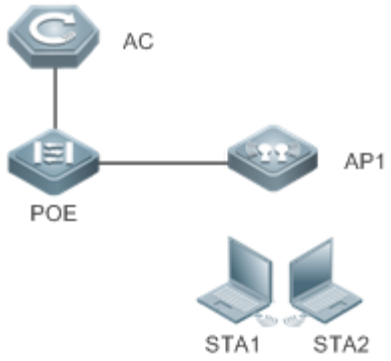
Verification

- Run the show run command to display configuration information.

Configuration Example

Enabling the Broadcast Wireless Forwarding Function

Figure 7-3



Configuration Steps	Enable the broadcast wireless forwarding function in global configuration mode.
AC/AP	`Ruijie#configure terminal` `Ruijie(config)#data-plane wireless-broadcast enable`
Verification	Run the **show running-config** command to display the configuration.
AC/AP	`Ruijie# show ap-config running` `!` `cwmp` `!` `data-plane wireless-broadcast enable` `!`

Common Errors

- N/A

7.5 Monitoring

- N/A

8 Configuring WLOG

8.1 Overview

WLOG (WLAN Log) enables storing and viewing wireless network and STA status in a past period of time. By collecting and storing the information of wireless network, AP and STA in the past 24 hours and then displaying the information through CLI commands, WLOG allows users to analyze the wireless network status and troubleshoot problems.

WLOG is for collecting and storage information, but does not support automatic information analysis temporarily. The WLOG feature is dedicated to enabling users, with provided information, to have a more accurate understanding of the wireless network and STA status in the past 24 hours to analyze and troubleshoot problems.

Protocols and Standards

- N/A

8.2 Applications

Application	Description
Fit AP Networking	The fit AP networking includes at least one AC and one AP.

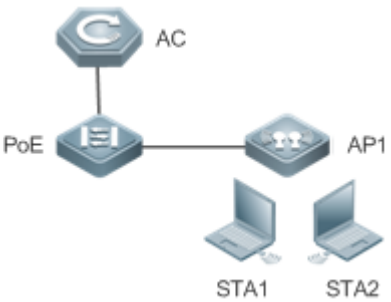
8.2.1 Fit AP Networking

Scenario

Deploy an AC device in a wireless network to query the information on the whole network, AP and STA associated with the AC device.

Figure 8-1 shows the networking topology for viewing the information on the whole network, AP and STA associated with the AC device.

Figure 8-1



Note:	AC: wireless controller PoE: switch, acted as the gateway of the AP

	AP: wireless access device STA1 and STA2: user devices, used as STA

Deployment

- Enable the WLOG feature on an AC device.

8.3 Features

Basic Concepts

Two Modes of Information Collection on the AC

- Periodic Collection

The general information of the whole network, AP and STA is collected and stored on a regular basis (once/1 hour). The general AP and STA information covers all the information of online APs and STAs.

- Reception Advertisement Collection

When an AP behavior of "AP Behavior Type" occurs, the WLOG module is informed to collect and store the information of the behavior.

When a STA behavior of "STA Behavior Type" occurs, the WLOG module is informed to collect and store the information of the behavior.

The information collection on the AP covers only periodic collection of spatial information on all online STAs.

General Information on the Whole Network

- Continuous operation time of the AC
- Number of online APs
- Number of preset but offline APs
- Versions of online APs (number of APs of each version)
- The information on each WLAN (SSID) STA includes:
- Number of online STAs which have passed Web authentication
- Number of online STAs which have passed 802.1x authentication
- Number of online STAs which are authentication-free

General Information on the AP

- AP name
- AP MAC address
- AP IP address
- AP uptime

- Status of each wired port of the AP
- Input/output rate (bits/sec) in last 5 minutes
- Statistics of input/output of unicast, broadcast, multicast and error frames
- General information on each radio
- Working channel
- Transmit power (dBm, absolute value)
- Number of associated online STAs
- Number of online STAs which have passed Web authentication
- Number of online STAs which have passed 802.1x authentication
- Intensity of the co-channel interference signal
- Number of received error frames
- Packet retransmission times

General Information on the STA

- IP address
- Signal strength
- Access rate
- Associated AP, radio and SSID

STA's Spatial Information

- The STA's spatial information mainly includes the statistics of data frame and management frame of the STA, as well as the statistics of each type of rate, as detailed below:
- Number of data frames successfully transmitted (from the AP to the STA)/total traffic
- Number of unresponsive data frames/total traffic
- Number of management frames/total traffic
- Statistics of each type of frames with access rate (The access rate is divided into 8 grades for statistics)

Grade	0	1	2	3	4	5	6	7
Access Type (Mbps)	1/2	5.5/11	6/9	12/18	24/36	48/54	Reserved	Reserved

- Statistics of each type of frame with MIMO rate (The MIMO rate is divided into 8 grades for statistics)

Grade	0	1	2	3	4	5	6	7
MIMO Type	mcs0 mcs1	mcs2 mcs3	mcs4 mcs5	mcs6 mcs7	mcs8 mcs9	mcs10 mcs11	mcs12 mcs13	mcs14 mcs15

The spatial information is mainly used to check whether the STA is in low-speed state, whether the proportion of the case in which no ACK frame is transmitted is too high, and whether too many management frames are transmitted and received, so as to further analyze and locate the network problems caused by low speed node, management frame attack, and poor

condition. The STA's spatial information varies in real time, and the current collection frequency is once every five minutes. The information is saved only on the AP due to large data volume.

AP Behavior Type

The AP behavior type includes going online, going offline and CAPWAP connection failure.

STA Behavior Type

The STA behavior type includes: association, de-association, Web authentication going online, Web authentication offline, 802.1X authentication going online, and 802.1X authentication offline.

Features

Feature	Description
Enabling the WLOG Feature	You can enable the WLOG feature to automatically collect AC, AP and STA information.
Synchronizing STA Go-online/offline Information to the ELOG Server	Synchronize STA go-online/offline information to the ELOG server.
Configuring the AP Detective Function	An AP detects information about STAs and hotspots nearby.
Synchronizing Information Detected by an AP to the ELOG Server	An AC synchronizes STA information and hotspot information detected by an AP to the ELOG server.

8.3.1 Enabling the WLOG Feature

After the WLOG feature is enabled, the AC or AP automatically collects AC, AP and STA information and records the information into memory, enabling users, with provided information, to have a more accurate understanding of the wireless network and STA status in the past 24 hours and analyze and troubleshoot problems.

Working Principle

After the WLOG feature is enabled, the AC or AP automatically collects AC, AP and STA information and records the information into memory, and receives online/offline advertisement of the AP and STA and records into memory for users to view.

8.3.2 Synchronizing STA Go-online/offline Information to the ELOG Server

After the WLOG function is enabled and the ELOG server URL is configured, the AC sends STA information to the ELOG server when a STA goes online or offline.

Working Principle

After the WLOG function is enabled and the AC receives the STA go-online/offline notice, the AC sends STA information in a specific format to the ELOG server.

8.3.3 Configuring the AP Detective Function

The AP detective function is used to detect STAs and hotspots around an AP. The AP detective function can be configured to detect either or both of STAs and hotspots.

Working Principle

After an AC delivers the command of enabling the AP detective function, the AP periodically reports the detected information to the AC for reprocessing.

8.3.4 Synchronizing Information Detected by an AP to the ELOG Server

An AC reports information detected by an AP to the ELOG server.

Working Principle

An AC reports information detected by an AP in a specific format to the ELOG server.

8.4 Configuration

Configuration	Description and Command	
Enabling the WLOG Feature	⚠ (Mandatory) It is used to enable the WLOG feature.	
	wlan diag enable	Enables the WLOG feature
Synchronizing STA Go-online/offline Information to the ELOG Server	⚠ (Optional) It is used to synchronize STA go-online/offline information to the ELOG server.	
	web-server enable api-path assoc-sta url url	Configures the address of the ELOG server.
Configuring the AP Detective Function	(Optional) It is used to enable the detective function of an AP.	
	ap-probe ap enable	Enables the hotspot information detective function of an AP.
	ap-probe sta enable	Enables the STA information detective function of an AP.
	ap-probe cache-time	Configures the time for caching detected information (aging) for an AP.
	ap-probe upload-time	Configures the interval for periodically reporting detected information for an AP.
	ap-probe limit	Configures the number of non-repetitive detected information records that can be received within aging period for the AP.

Synchronizing Information Detected by an AP to the ELOG Server	(Optional) It is used to synchronize information detected by an AP to the ELOG function.	
	web-server enable api-path probe-ap url *url*	Configures the ELOG address to which the hotspot information detected by an AP is synchronized.
	web-server enable api-path probe-sta url *url*	Configures the ELOG address to which the STA information detected by an AP is synchronized.

8.4.1 Enabling the WLOG Feature

Configuration Effect

- After the WLOG feature is enabled, the AC or AP automatically records the AC, AP and STA information.

Notes

- Enabling the WLOG feature pre-allocates memory. If the memory is not sufficient, the WLOG feature cannot be enabled. Disabling the WLOG feature frees all memory for information storage and pre-allocated memory.

Configuration Steps

↘ Enabling the WLOG Feature

- (Mandatory) Run the **wlog diag enable** command to enable the WLOG feature.
- Enable the WLOG feature in global configuration mode of the AC device.
- After the WLOG feature is enabled, information is collected and recorded into memory on a regular basis.

Command	**wlan diag enable**
Parameter Description	N/A
Defaults	By default, the WLOG feature is disabled on the AC and AP device.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show wlan diag network** command to check whether the whole network information can be viewed on the AC.
- Run the **show wlan diag sta** command to check whether the STA information can be viewed on the AP.

Configuration Example

↘ Enabling the WLOG Feature

Scenario **Figure 8-2**	Configuration Steps	● Enable the WLOG feature in global configuration mode.
AC	`Ruijie# configure terminal` `Ruijie(config)# wlan diag enable`
Verification	Use the **show wlan diag network** command to display the general information of the whole network.
AC	`Ruijie# show wlan diag network` `Time: 2017-05-05 14:57:07` `AC uptime: 10 h` `Online AP: 1` `Offline AP:0` `Online AP Version:` `PID HwVer SwVer AP Number` `--- --- ---` `AP520 1.00 AP_RGOS 11.1(5)B9P2, Release(04162423) 1` `Wlan information:` `WLAN ID SSID Active STA WEB Auth 1X Auth Other` `--- --- --- --- --- ---` `4 wlan-guest 2 2 0 0` `5 wlan-802.1x 6 0 6 0`

8.4.2 Synchronizing STA Go-online/offline Information to the ELOG Server

Configuration Effect

- After the WLOG function is enabled and the ELOG server URL is configured, the AC sends the STA go-online/offline information to the ELOG server.

Notes

- This function is triggered by the STA go-online/offline action. Before the function is enabled, the STA go-online/offline information is not sent to the ELOG server.

Configuration Steps

↘ Configuring the URL of the ELOG Server

- The complete address of the ELOG server needs to be configured.

Command	**web-server enable api-path assoc-sta url** *url*
Parameter Description	*url*: indicates the complete address of the ELOG server.
Defaults	By default, The ELOG server URL is not configured, that is, the AC does not interwork with the ELOG server.
Command Mode	Global configuration mode
Usage Guide	To ensure smooth data transmission, the WLOG function needs to be enabled. In local forwarding scenarios, if the AC does not obtain the STA IP address (which can be queried by running the **show ac-config client** command) after the STA goes online, run the **ip dhcp snooping** command in global configuration mode to ensure that the AC can obtain the STA IP address. Up to eight Elog servers are supported.

Verification

- Run the **show running** command to display configurations.

Configuration Example

↘ Configuring the URL of the ELOG Server

Configuration Steps	● In global configuration mode, configure two Elog server URLs.
AC	`Ruijie# configure terminal` `Ruijie(config)#web-server enable api-path assoc-sta url http://172.18.155.14:8080/elog/service/dc/updateSta` `Ruijie(config)# web-server enable api-path assoc-sta url http://172.18.155.15:8080/elog/service/dc/updateSta`
Verification	Run the **show running-config** command to display configurations.

AC	Ruijie# show running-config ! web-server enable api-path assoc-sta url http://172.18.155.14:8080/elog/service/dc/updateSta http://172.18.155.14:8080/elog/service/dc/updateSta web-server enable api-path assoc-sta url http://172.18.155.15:8080/elog/service/dc/updateSta !

Common Errors

- Only an IP address instead of a complete URL is specified in the URL parameter.

Common Errors

- N/A

8.4.3 Configure the AP Detective Function

Configuration Effect

After an AC delivers the command of enabling the AP detective function, the AP periodically reports detected STA information and hotspot information to the AC.

Configuration Steps

Enabling the Hotspot Information Detective Function of an AP

- Optional. After the function is enabled, an AP can detect hotspot information.

Command	**ap-probe ap enable**
Parameter Description	*N/A*
Defaults	This function is not configured by default.
Command Mode	AP configuration mode, AP group configuration mode, and all-AP configuration mode
Usage Guide	N/A

Enabling the STA Information Detective Function of an AP

- Optional. After the function is enabled, an AP can detect STA information.

Command	**ap-probe sta enable**
Parameter Description	*N/A*
Defaults	This function is not configured by default.

Command Mode	AP configuration mode, AP group configuration mode, and all-AP configuration mode
Usage Guide	N/A

Configuring the Time for Caching Detected Information (Aging) for an AP

- Optional. Configure the time for caching detected information by an AP on the AP.

Command	**ap-probe cache-time** *time*
Parameter Description	*time*: Indicates the cache time(aging time). The value ranges from 0 to 3600 seconds.
Defaults	The default value is 120 seconds.
Command Mode	AP configuration mode, AP group configuration mode, and all-AP configuration mode
Usage Guide	When the time is set to **0**, detected information is not cached on the AP. As a result, considerable repeated information is reported to the AC, and the CPU usage is very high due to frequent transmission of packets, which affects the wireless service. Therefore, it is set to **0** during commissioning and it is not recommended to **0** in normal cases.

Configuring the Interval for Periodically Reporting Detected Information for an AP

- Optional. Configure the interval for periodically reporting detected information for an AP.

Command	**ap-probe upload-time** *time*
Parameter Description	*time*: Indicates the interval for periodically reporting detected information. The value ranges from 1 to 300 seconds.
Defaults	The default value is 5 seconds.
Command Mode	AP configuration mode, AP group configuration mode, and all-AP configuration mode
Usage Guide	N/A

Configuring the Maximum Number of Detected Information Records That Can Be Cached on an AP

- Optional. Configure the number of non-repetitive detected information records that can be received within the aging period for the AP.

Command	**ap-probe limit** *num*
Parameter Description	*num*: Indicates the number of detected information records that can be cached on an AP. The value ranges from 1 to 65535 and the maximum value depends on the number of detected information records supported by the AP.
Defaults	The default value is 100.
Command Mode	AP configuration mode, AP group configuration mode, and all-AP configuration mode
Usage Guide	If the configured value of *num* exceeds the maximum number of information records supported by an AP, the maximum number of information records supported by the AP prevails. Cached information occupies certain memory resources. Therefore, it is not recommended to set it to a large number.

Verification

- Run the **show running** command to display the configuration in AP group configuration mode and all-AP configuration mode.
- Run the **show ap-config running** command to display the configuration in AP configuration mode.

Configuration Example

↘ Enabling the Snooping Function of AP 1

Configuration Steps	● Enable the hotspot and STA detective function in AP configuration mode. Set the cache time to 60 seconds, report interval to 6 seconds, and the number of non-repetitive detected information that can be cached to 200.
AC	`Ruijie# configure terminal` `Ruijie(config)#ap-config AP1` `You are going to config AP(AP1), which is online now.` `Ruijie(config-ap)#ap-probe ap enable` `Ruijie(config-ap)#ap-probe sta enable` `Ruijie(config-ap)#ap-probe cache-time 60` `Ruijie(config-ap)#ap-probe upload-time 6` `Ruijie(config-ap)#ap-probe limit 200` `Ruijie(config-ap)#`
Verification	Run the **show ap-config running** command to display the configuration.
AC	`Ruijie# show ap-config running` `!` `ap-config AP1` ` ap-mac 1234.1234.5656` ` ap-probe sta enable` ` ap-probe ap enable` ` ap-probe upload-time 6` ` ap-probe cache-time 60` ` ap-probe limit 200` `!`

8.4.4 Synchronizing Information Detected by an AP to the ELOG Server

Configuration Effect

- After the hotspot information detective function of an AP is enabled and the URL of the ELOG server, to which the detected hotspot information is synchronized, is configured, the AC sends the snooped hotspot information reported by the AP to the ELOG server.
- After the STA information detective function of an AP is enabled and the URL of the ELOG server, to which the detected

STA information is synchronized, is configured, the AC sends the detected STA information reported by the AP to the ELOG server.

Configuration Steps

Configuring the URL of the ELOG Server to Which Hotspot Information Detected by an AP Is Synchronized

- The complete address of the ELOG server needs to be configured.

Command	**web-server enable api-path probe-ap url** *url*
Parameter Description	*url*: Indicates the complete address of the ELOG server for storing detected hotspot information.
Defaults	By default, The ELOG server URL is not configured, that is, an AC is not interconnected to the ELOG server.
Command Mode	Global configuration mode
Usage Guide	A maximum of eight ELOG servers can be configured.

Configuring the URL of the ELOG Server to Which STA Information Snooped by an AP Is Synchronized

- The complete address of the ELOG server needs to be configured.

Command	**web-server enable api-path probe-sta url** *url*
Parameter Description	*url*: Indicates the complete address of the ELOG server for storing detected STA information.
Defaults	By default, The ELOG server URL is not configured, that is, an AC is not interconnected to the ELOG server.
Command Mode	Global configuration mode
Usage Guide	A maximum of eight ELOG servers can be configured.

Verification

Run the **show running** command to display configurations.

Configuration Example

Configuring the URL of the ELOG Server to Which Information Snooped by an AP Is Synchronized

Configuration Steps	• In global configuration mode, set the URL of the first ELOG server for storing detected hotspot information to http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSsid and the URL of the second ELOG server to http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSsid. • In global configuration mode, set the URL of the first ELOG server for storing detected STA information to http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSta and the URL of the second ELOG server to http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSta.
AC	`Ruijie# configure terminal` `Ruijie(config)# web-server enable api-path probe-ap url http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSsid` `Ruijie(config)# web-server enable api-path probe-ap url`

	http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSsid Ruijie(config)# web-server enable api-path probe-sta url http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSta Ruijie(config)# web-server enable api-path probe-sta url http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSta
Verification	Run the **show running-config** command to display configurations.
AC	Ruijie# show running-config ! web-server enable api-path probe-ap url http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSsid http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSsid web-server enable api-path probe-sta url http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSta http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSta!

8.5 Monitoring

Displaying

Description	Command
Displays the general information on the whole network	**show wlan diag network**
Displays the AP information on the AC	**show wlan diag ap** [**ap-mac** *ap-mac*] [**number** *number*]
Displays the STA information on the AC	**show wlan diag sta** [**sta-mac** *sta-mac*] [**ip-range** *ip-prefix*] [**action** *action* [**result** *result*]] [**number** *number*]

9 Configuring Roaming

9.1 Overview

Roaming is a function that allows re-association of stations (STAs) with access points (APs) when STAs move in the coverage areas of different APs.

The roaming function enables moving STAs to maintain the ongoing IP communication and enjoy all applications and services. Roaming is transparent and seamless for users without data interruption.

If STAs move in different areas in a wireless environment, the roaming function must be supported. Roaming scenarios are classified into two types: intra-AC roaming and inter-AC roaming.

- Intra-AC roaming is applicable for deployments having only one access controller (AC).
- Inter-AC roaming is applicable for deployments having multiple ACs.

Protocols and Standards

- N/A

9.2 Applications

Application	Description
Intra-AC Roaming	One STA is associated with AP1 joined to one AC, and then moves to the coverage of AP2 joined to the same AC and is associated with AP2.
Inter-AC Roaming	One STA is associated with AP1 joined to AC1, and then moves to the coverage of AP2 joined to AC2 and is associated with AP2.

9.2.1 Intra-AC Roaming

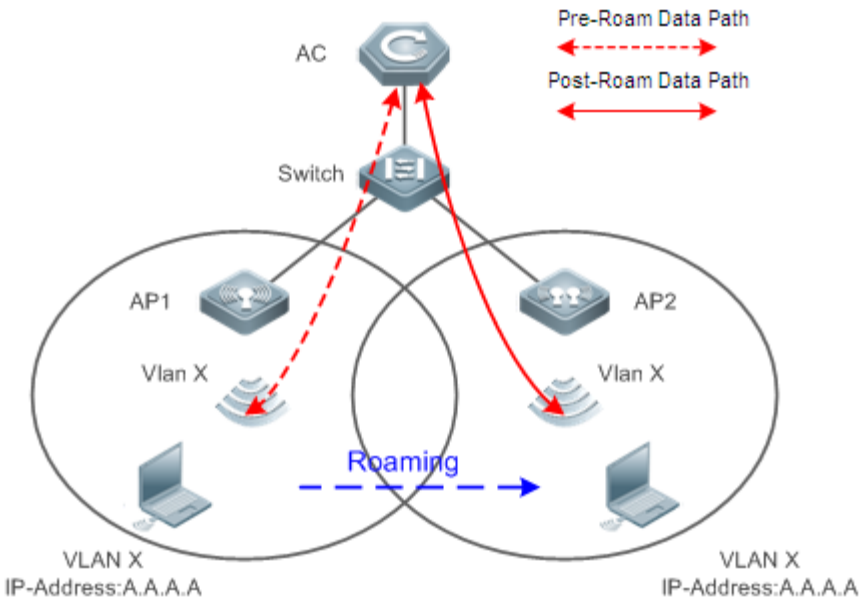
Scenario

One STA is associated with AP1 joined to one AC, and then moves to the coverage of AP2 joined to the same AC and is associated with AP2.Based on the entity (AC or AP) that forwards data, intra-AC roaming is further classified into intra-AC L2/L3 roaming in centralized forwarding mode and intra-AC L2/L3 roaming in local forwarding mode.

9.2.1.1 Intra-AC L2/L3 Roaming in Centralized Forwarding Mode

Figure 9-1 shows intra-AC L2/L3 roaming in centralized forwarding mode.

Figure 9-1 Intra-AC L2/L3 Roaming in Centralized Forwarding Mode



Remarks	VLAN X indicates the VLAN ID associated with the STA. (If the VLAN X corresponding to AP2 is changed to VLAN Y, L3 roaming occurs.)

Unlike L2 roaming, VLANs associated with the STA are different before and after roaming. Except this difference, other processing is the same in L2 and L3 roaming. Therefore, L2 roaming and L3 roaming are not discussed separately hereinafter.

Deployment

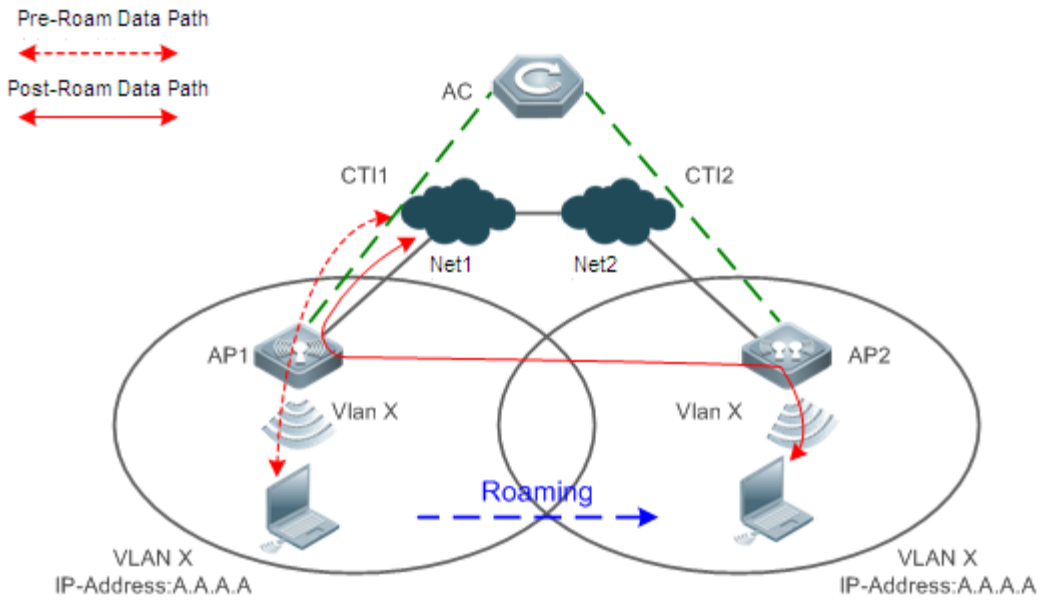
- AP1 and AP2 are associated with the AC through switches and are assigned to the same WLAN.
- At first, the STA is associated with AP1, and the obtained IP address is A.A.A.A.
- Later, the STA moves to the coverage of AP2, and is associated with AP2. The IP address remains unchanged without communication interruption.

STA roaming is implemented only when the wireless service set identifiers (SSIDs) provided by AP1 and AP2 are the same.

9.2.1.2 Intra-AC L2/L3 Roaming in Local Forwarding Mode

Figures 9-2 shows intra-AC L2/L3 roaming in local forwarding mode.

Figure 9-2 Intra-AC L2/L3 Roaming in Local Forwarding Mode



Remarks	CTI is the communication tunnel between an AP and an AC. VLAN X indicates the VLAN ID associated with the STA.

Deployment

- AP1 and AP2 set up a control channel with the AC through the CTI, and are assigned with the same WLAN. The corresponding VLAN is VLAN X.
- AP1 and AP2 work in local forwarding mode. At first, the STA is associated with AP1, and the obtained IP address is A.A.A.A.
- Later, the STA moves to the coverage of AP2, and is associated with AP2. The IP address remains unchanged without communication interruption.
- Before roaming, the data is directly sent out by AP1. After roaming, the data is forwarded from AP2 to AP1, and then sent out by AP1.

STA roaming is implemented only when the wireless SSIDs provided by AP1 and AP2 are the same.

9.2.2 Inter-AC Roaming

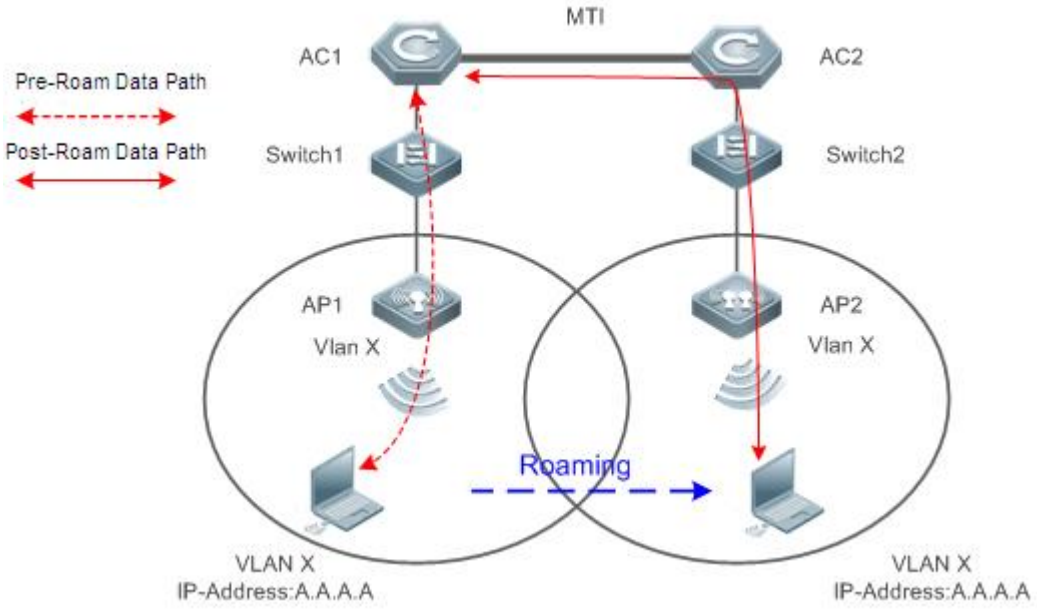
Scenario

One STA is associated with AP1 joined to AC1, and then moves to the coverage of AP2 joined to AC2 and is associated with AP2.Based on the entity (AC or AP) that forwards data, inter-AC roaming is further classified into inter-AC roaming in centralized forwarding mode and inter-AC roaming in local forwarding mode.

9.2.2.1 Inter-AC L2/L3 Roaming in Centralized Forwarding Mode

Figure 9-3 shows inter-AC L2/L3 roaming in centralized forwarding mode.

Figure 9-3 Inter-AC L2/L3 Roaming in Centralized Forwarding Mode



Remarks	VLAN X indicates the VLAN ID associated with the STA. MTI is the communication tunnel between ACs.

Deployment

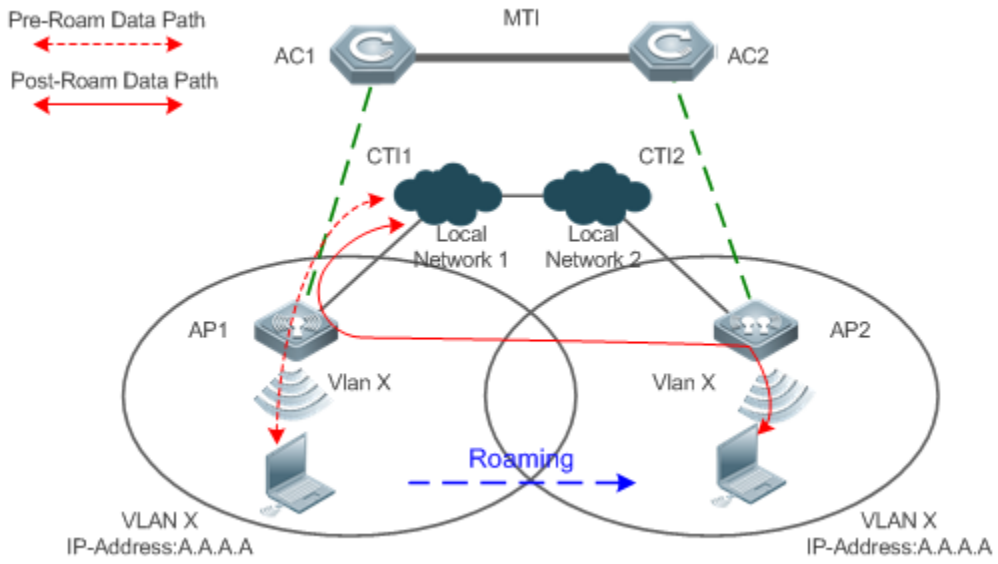
- AC1 and AC2 are configured as the mobility member of the peer AC, and can communicate with each other.
- AP1 is connected to AC1, and AP2 is connected to AC2. Both AP1 and AP2 are assigned to the same WALN. The corresponding VLAN is VLAN X.
- At first, the STA is associated with AP1, and the obtained IP address is A.A.A.A. Later, the STA moves to the coverage of AP2, and is associated with AP2. The IP address remains unchanged without communication interruption.
- Before roaming, the data is directly sent out by AC1. After roaming, the data is forwarded from AC2 to AC1 through the MTI, and then sent out by AC1.

⚠ STA roaming is implemented only when the wireless SSIDs provided by AP1 and AP2 are the same.

9.2.2.2 Inter-AC L2/L3 Roaming in Local Forwarding Mode

Figure 9-4 shows inter-AC L2/L3 roaming in local forwarding mode.

Figure 9-4 Inter-AC L2/L3 Roaming in Local Forwarding Mode



Remarks	VLAN X indicates the VLAN ID associated with the STA. MTI is the communication tunnel between ACs, and CTI is the communication tunnel between APs and ACs.

Deployment

- AC1 and AC2 are included in the same mobility group, and are configured as the mobility member of the peer AC.
- AP1 is connected to AC1, and AP2 is connected to AC2. Both AP1 and AP2 are assigned to the same WALN. The corresponding VLAN is VLAN X. Both AP1 and AP2 work in local forwarding mode.
- At first, the STA is associated with AP1, and the obtained IP address is A.A.A.A. Later, the STA moves to the coverage of AP2, and is associated with AP2. The IP address remains unchanged without communication interruption.
- Before roaming, the data is directly sent out by AP1. After roaming, the data is forwarded from AP2 to AP1, and then sent out by AP1.

⚠ STA roaming is implemented only when the wireless SSIDs provided by AP1 and AP2 are the same.

9.3 Features

Basic Concepts

Association and Re-Association

Association: A STA selects an extended service area, and sends the asso frame to set up a connection with this extended service area.

Re-association: A STA moves from a basic service area of an extended service area to another basic service area of this extended service area, and is associated with a new AP. In this case, the STA sends the reasso frame.

STA, AP, and AC

STA: It is a wireless workstation that is equipped with the wireless network interface card (NIC), such as a laptop computer or a mobile phone.

AP:It is a wireless access point that provides radio signals so that the STA can access the wireless network.

AC: It is a wireless access controller that provides wireless connection and related service functions.

L2 Roaming and L3 Roaming

L2 roaming: The VLAN to which a STA belongs remains unchanged before and after roaming.

L3 roaming: The VLAN to which a STA belongs changes after roaming.

Centralized Forwarding and Local Forwarding

Centralized forwarding: All packets of a STA are forwarded by the AC.

Local forwarding: Control packets of a STA are processed by the AC, whereas data packets are directly forwarded by the AP.

Intra-AC Roaming and Inter-AC Roaming

Intra-AC roaming:A STA roams from one AP joined to an AC to another AP joined to the same AC.

Inter-AC roaming:A STA roams from an AP joined to an AC to another AP joined to a different AC.

Home AC and Foreign AC

- Home AC (HA): When a STA is associated with an AC in the mobility group for the first time, this AC is called HA of the STA.
- Foreign AC (FA): A STA is currently connected to an AC that is not the HA. This AC is called FA of the STA.

For the intra-AC roaming, the HA is the same as the FA.

Overview

Feature	Description
Mobility Group	After a mobility group is configured, a STA can roam to different ACs in the same mobility group.

Mobility List	The mobility list is an extension of the mobility group. The number of AC members in the mobility group is limited. The mobilizing list is introduced to extend the roaming scope of STAs without affecting roaming of the mobility group.
Displaying STA Roaming Status and Roaming Tracks	Displays the current status of all roaming STAs on the local AC and the roaming track of a STA.
Suppressing STA Roaming Syslogs	Suppresses the output rate of STA roaming syslogs.

9.3.1 Mobility Group

The roaming scope of wireless STAs within a WLAN cannot be expanded without limit. To enable a STA to roam among APs joined to different ACs and manage the roaming scope of STAs, a mobility group is defined to include a group of ACs within the STA roaming scope.

Working Principle

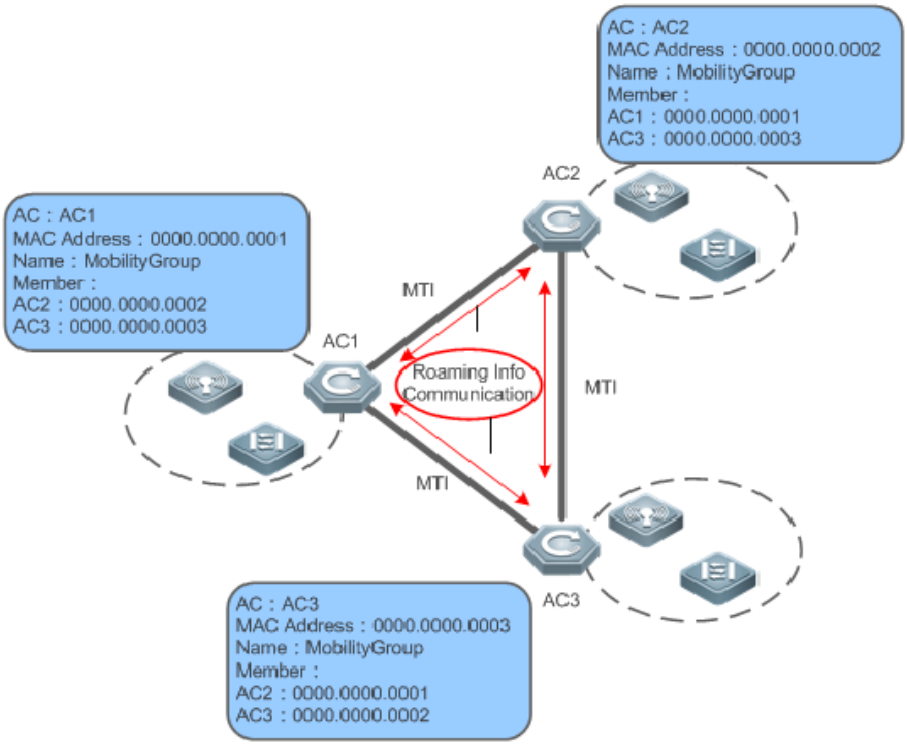
Each AC is configured with a list of other members of the mobility group. When a STA joins an AC, the AC sends out a message to all of the ACs in the mobility group. If it is the first time the STA accesses the mobility group, the initial AC (HA) will save information about the STA. When the STA roams to another AC (FA), the HA synchronizes the STA information to the FA. If this STA is roaming, the HA synchronizes the STA information to the current AC (FA) after receiving a message.

Generally, the roaming STA information is exchanged only after roaming occurs. Before roaming occurs, the information synchronization function of the mobility group can be used to proactively share STA information among ACs in the mobility group. This saves time in STA roaming and improves the roaming efficiency.

↘ Topology of the Mobility Group

ACs in the mobility group encapsulate and transfer roaming information through the Controlling and Provisioning of Wireless Access Point (CAPWAP) tunnel. The unique technology reduces the re-authentication time on the Radius server after inter-AC roaming of STAs, and accelerates information authentication of roaming STAs, laying a solid foundation for seamless roaming. Figure 9-2 shows the topology of the mobility group.

Figure 9-5 Topology of the Mobility Group



Remarks	MTI is the communication tunnel between ACs. AC1, AC2, and AC3 are in the same mobility group. On each AC, another two ACs are configured as its mobility member.

9.3.2 Mobility List

The mobility list is an extension of the mobility group. The number of AC members in the mobility group is limited. The mobility list is introduced to extend the roaming scope of STAs without affecting roaming of the mobility group.

Working Principle

↘ Comparison Between the Mobility List and the Mobility Group

Data exchange of roaming STAs in the mobility list is similar with that in the mobility group. The major difference is as follows: Intra-group roaming adopts Proactive Key Caching (PKC), while inter-group roaming uses the mobility list that requires the roaming STA to complete the entire authentication process with the AAA/Radius server. Therefore, compared with intra-group roaming, inter-group roaming presents a relatively low efficiency. The common thing between the mobility group and the mobility list is that the roaming process is seamless and transparent for users.

A mobility group can be designated for a specific AC. Then, STAs associated with this AC can roam in this mobility group. In addition to configuration of a mobility group, you can also configure a mobility list on the AC. The member ACs in the mobility list must be in a mobility group different from that of the current AC. In this way, STAs on the current AC can roam across mobility groups.

9.3.3 Displaying STA Roaming Status and Roaming Tracks

To learn the roaming status and movements of all STAs on an AC, you can check the status and roaming tracks of current roaming STAs.

Working Principle

Information about roaming STAs is recorded on the HA, including the roaming type, connected WLAN, as well as VLANs, APs, and pre-roaming/post-roaming radios. Such information is stored, and deleted only when the STA is deassociated.

⚠ The roaming track is recorded by default.

⚠ You can run the **show mobility user roam- track** command to display the tracks of roaming STAs.

9.3.4 Suppressing STA Roaming Syslogs

STA roaming syslog suppression prevents a high CPU usage caused by the large amount of syslogs output during roaming of a large number of STAs.

Working Principle

The number of syslog records output per second is counted. When this number reaches the upper limit, no more syslog is output within the second, thereby suppressing the syslogs. In the next second, the number of syslogs is counted again.

9.3.5 Preventing STA Roaming

Roaming prevention is configured to facilitate distribution and use of WLAN resources.

Working Principle

When an AC receives a roaming request, it checks whether the roam-in/roam-out WLAN has been configured with roaming prevention, If yes, the STA is prevented from roaming.

9.4 Configuration

Configuration	Description and Command	
Configuring a Mobility Group	⚠ (Optional) It is used to implement the inter-AC roaming function.	
	mobility-group	Configures a mobility group.
	member	Adds or deletes a mobility member to or from the mobility group.
Configuring Proactive Information Exchange Within the Mobility Group	⚠ (Optional) It is used to exchange STA information within the mobility group.	
	mobility-fast	Enables proactive information exchange within the mobility group.
Configuring a Mobility List	⚠ (Optional) It is used to add members to a mobility list.	

	list	Adds or deletes member ACs to or from the mobility list.
Configuring the Maximum Number of Times a Keepalive Packet Can Be Transmitted	(Optional) It is used to configure the maximum number of times a keepalive packet can be transmitted. If this number is exceeded, the keepalive attempt fails.	
	keepalive-count	Configures the maximum number of times a keepalive packet can be transmitted
Configuring the Interval at Which a Keepalive Packet Is Sent	(Optional) It is used to configure the interval at which a keepalive packet is sent.	
	keepalive-interval	Configures the interval at which a keepalive packet is sent.
Testing Roaming Connectivity	(Optional) It is used to test whether ACs in the mobility are interconnected properly.	
	mti-ping	Tests the connectivity of tunnels between ACs in the mobility group.
Suppressing STA Roaming Syslogs	(Optional) It is used to suppress the output rate of STA roaming syslogs.	
	roaming logging rate-limit	Sets the output rate of STA roaming syslogs.
Preventing STA Roaming	(Optional) It is used to prevent STA roaming.	
	no roaming support wlan	Prevents STA roaming.

9.4.1 Configuring a Mobility Group

Configuration Effect

- Configure a mobility group and add a mobility member to implement inter-AC roaming.
- The centralized forwarding mode is configured in the same way as the local forwarding mode.

Notes

- The precondition of inter-AC roaming is that the two ACs can communicate with each other normally.

Configuration Steps

Creating a Mobility Group

- (Optional) The configuration is mandatory if inter-AC roaming should be implemented. Run the **mobility-group** *group-name* command to create a mobility group.
- Configure at least one mobility group on every AC that involves inter-AC roaming.

Up to eight mobility groups can be created on an AC.

Command	**mobility-group** *group-name*

Parameter Description	*group-name*: Specifies the name of a mobility group.
Defaults	No mobility group is configured by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Adding Mobility Members

- (Optional) The configuration is mandatory if inter-AC roaming should be implemented.
- Add at least one member to a mobility group on every AC that involves inter-AC roaming.
- After a mobility group is created, there is no mobility member in the group. Therefore, you need to add one or more mobility members.
- To ensure efficiency and reliability of information synchronization between ACs within a mobility group, you must limit the number of members in the mobility group. A mobility group supports up to 24 AC members.

Command	**member** {*ip-address*|*ipv6-address*}
Parameter Description	*ip-address:* Indicates the IPv4 address of a mobility member. *ipv6-address:* Indicates the IPv6 address of an mobility member.
Defaults	A newly created mobility group does not contain any member.
Command Mode	Mobility group configuration mode
Usage Guide	N/A

Verification

Check the mobility group information to determine whether members are successfully added and whether the connections are normal.

Configuration Example

All the configuration examples in this document are provided for the scenario of inter-AC roaming in centralized forwarding mode.

Configuring a Mobility Group and Adding a Member to this Group

Scenario **Figure 9-6**	 ● Inter-AC or intra-AC Roaming Scenario
Configuration Steps	● Set the loopback address of AC1 to 192.168.1.1 and the loopback address of AC2 to 192.168.1.2, and ensure that one AC can be pinged successfully from another AC. ● Add a mobility group. ● Add a mobility member.
AC1	Ruijie#configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)#mobility-groupmgroup_name Ruijie(config-mobility)#member 192.168.1.1
AC2	Ruijie#configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)#mobility-groupmgroup_name Ruijie(config-mobility)#member 192.168.1.2
Verification	Check the mobility group information to determine the configurations are successful. ● Run the **show mobility status** *mgroup_name* command on every AC.

AC1	Ruijie# show mobility status mgroup_name Mobility Group mgroup_name Mobility Keepalive Interval..... 10 Mobility Keepalive Count..... 3 Mobility Group Status..... normal Mobility Members: IP Address Client/Server Data Tunnel Ctrl Tunnel 192.168.1.1Client OK OK Mobility List Members:
AC2	Ruijie# show mobility status mgroup_name Mobility Group mgroup_name Mobility Keepalive Interval..... 10 Mobility Keepalive Count..... 3 Mobility Group Status..... normal Mobility Members: IP Address Client/Server Data Tunnel Ctrl Tunnel 192.168.1.2Client OK OK Mobility List Members:

Common Errors

- Mobility AC members fail to ping each other.
- The mobility group or members are not configured on an AC.
- The mobility group names are inconsistent.

9.4.2 Configuring Proactive Information Exchange within the Mobility Group

Configuration Effect

- When roaming does not occur, an AC also shares the STA information with other AC members in the mobility group.

Notes

- A mobility group must be configured.

Configuration Steps

- (Optional) After configuring a mobility group on ACs, enter mobility group configuration mode and enable proactive information exchange.
- (Optional) Configure fast roaming as required.

Command	mobility-fast
Parameter Description	N/A
Defaults	Proactive information exchange is disabled by default.
Command Mode	Mobility group configuration mode
Usage Guide	N/A

Verification

- Check the mobility group information. If the mobility group status is Fast Mode, the configuration is successful.

Configuration Example

Configuring Proactive Information Exchange within the Mobility Group

Configuration Steps	• Configure a mobility group.(The configurations are omitted here.) • Enable proactive information exchange within the mobility group.
AC	Ruijie#configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)#mobility-groupmgroup_name Ruijie(config-mobility)# mobility-fast
Verification	Check the mobility group information.
AC	Ruijie# show mobility status mgroup_name Mobility Group mgroup_name Mobility Keepalive Interval..... 10 Mobility Keepalive Count..... 3 Mobility Group Status..... Fast Mode .....

Common Errors

- N/A

9.4.3 Configuring a Mobility List

Configuration Effect

- When no more members can be added to the mobility groups, apply the mobility list to implement roaming.

Notes

- A mobility group must be configured.

Configuration Steps

- (Optional) Add members to the mobility list after a mobility group is configured on the AC. Run the **list** { *ip-address* | *ipv6-address* } command to add a member to the mobility list.
- If the number of mobility members exceeds the capacity of the mobility group, you can add members to the mobility list as an alternative.

A mobility list supports up to 72 members.

Command	**list** {*ip-address*| *ipv6-address*}
Parameter Description	*ip-address*: Indicates the IPv4 address of a mobility member. *ipv6-address:* Indicates the IPv6 address of a mobility member.
Defaults	No mobility list is configured by default.
Command Mode	Mobility group configuration mode
Usage Guide	N/A

Verification

- Check the mobility group information to determine whether added members exist.

Configuration Example

Configuring a Mobility List

Configuration Steps	● Configure a mobility group. (The configurations are omitted here.) ● Add members to the mobility list.
AC	Ruijie#configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)#mobility-groupmgroup_name Ruijie(config-mobility)# list 192.168.1.1 Ruijie(config-mobility)# list 192.168.1.2

Verification	Check the mobility list information.
AC	Ruijie# show mobility status mgroup_name Mobility Group mgroup_name Mobility Keepalive Interval..... 10 Mobility Keepalive Count..... 3 Mobility Group Status..... Fast Mode Mobility Members: IP Address Client/Server Data Tunnel Ctrl Tunnel Mobility List Members: IP Address Client/Server Data Tunnel Ctrl Tunnel 192.168.1.2 Client OK OK 192.168.1.1 Client OK OK

Common Errors

- N/A

9.4.4 Configuring the Maximum Number of Times a Keepalive Packet Can Be Transmitted

Configuration Effect

- (Optional) Configure the maximum number of times a keepalive packet can be transmitted. If this number is exceeded, the keepalive attempt fails.

Notes

- A mobility group must be configured and have at least one mobility member.

Configuration Steps

- (Optional) Configure a mobility group on the AC, and enter mobility group configuration mode.
- The maximum number of times a keepalive packet can be transmitted is not modified by default. If the network environment is unstable, you can increase this value.

Command	**keepalive-count** *counts*
Parameter Description	*counts*: Indicates the keepalive times. The value ranges from 2 to 30.

Defaults	4 times after a mobility group is created
Command Mode	Mobility group configuration mode
Usage Guide	N/A

Verification

- Check the mobility group information. The maximum number of times a keepalive packet can be transmitted should be displayed.

Configuration Example

↘ Configuring the Maximum Number of Times a Keepalive Packet Can Be Transmitted

Configuration Steps	● Configure a mobility group. (The configurations are omitted here.) ● Set the maximum number of times a keepalive packet can be transmitted to 5.
AC	`Ruijie(config)#mobility-group mgroup_name` `Ruijie(config-mobility)# keepalive-count 5`
Verification	Check the mobility group configurations.
AC	`Ruijie# show mobility status mgroup_name` `Mobility Group mgroup_name` `Mobility Keepalive Interval..... 10` `Mobility Keepalive Count..... 5` `Mobility Group Status..... normal`

Common Errors

- N/A

9.4.5 Configuring the Interval at Which a Keepalive Packet Is Sent

Configuration Effect

- (Optional) Configure the interval at which a keepalive packet is sent.

Notes

- A mobility group must be configured and have at least one mobility member.

Configuration Steps

- (Optional) Configure a mobility group on the AC, and enter mobility group configuration mode.

- The interval at which a keepalive packet is sent is 10s by default. If the network environment is unstable, you can increase the interval.

Command	**keepalive- interval** *seconds*
Parameter Description	*seconds*: Indicates the interval at which a keepalive packet is sent. The unit is second. The value ranges from 1 to 30.
Defaults	10s after a mobility group is created
Command Mode	Mobility group configuration mode
Usage Guide	N/A

Verification

- Check the mobility group information. The interval at which a keepalive packet is sent should be displayed.

Configuration Example

Configuring the Interval at Which a Keepalive Packet Is Sent

Configuration Steps	• Configure a mobility group. (The configurations are omitted here.) • Set the interval at which a keepalive packet is sent to 20s.
AC	`Ruijie(config)#mobility-group mgroup_name` `Ruijie(config-mobility)# keepalive-interval20`
Verification	Check the mobility group configurations.
AC	`Ruijie# show mobility status mgroup_name` `Mobility Group mgroup_name` `Mobility Keepalive Interval..... 20` `Mobility Keepalive Count..... 4` `Mobility Group Status..... normal`

Common Errors

- N/A

9.4.6 Testing Roaming Connectivity

Configuration Effect

- (Optional) Start a connectivity test to check whether member ACs are connected with each other normally.

Notes

- A mobility group must be configured and have at least one mobility member.

Configuration Steps

- (Optional) After configuring a mobility group on the AC, enter mobility group configuration mode to start a connectivity test.
- Start a connectivity test to check whether member ACs in the mobility group communicate with each other normally,.

Command	**mti-ping** {*ip-address*|*ipv6-address*}
Parameter Description	*ip-address*: Indicates the IPv4 address of a mobility member. *ipv6-address:* Indicates the IPv6 address of a mobility member.
Defaults	N/A
Command Mode	Mobility group configuration mode
Usage Guide	N/A

Verification

- Check the test results.

Configuration Example

Starting a Roaming Connectivity Test

Configuration Steps	• Configure a mobility group and add mobility members. (The configurations are omitted here.) • Start a roaming connectivity test.
AC	`Ruijie(config)#mobility-group my_group_name` `Ruijie(config-mobility)#mti-ping 192.168.1.2` `Sending 4, MTI packet to 192.168.1.1, timeout is 2 seconds:` `!!!!` `Success rate is 100 percent (4/4)`
Verification	Check the test results.
AC	`Sending 4, MTI packet to 192.168.1.1, timeout is 2 seconds:` `!!!!` `Success rate is 100 percent (4/4)`

Common Errors

- The **mti-ping** command is different from the **ping** command, that is, successful execution of the **ping** command does not mean that execution of the **mti-ping** command is also successful. The **mti-ping** command is applicable to mobility group members.

9.4.7 Suppressing STA Roaming Syslogs

Configuration Effect

- Even if STAs roam frequently, the number of roaming syslogs output per second does not exceed the limit.

Notes

- N/A

Configuration Steps

Configuring the Syslog Suppression Rate

- (Optional) The configuration is performed on the AC. Run the **roaming logging rate-limit** command to configure the syslog suppression rate.
- Configure the syslog suppression rate. A larger rate configured indicates that more syslogs can be output per second.

Command	**roaming logging rate-limit** *limit-num*
Parameter Description	*limit-num*: Indicates the rate, which is expressed in records per seconds. The value ranges from 1 to 10000.
Defaults	By default, less than five syslog records are output per second, that is, the maximum syslog output rate is 5 records per second.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to check whether the syslog suppression rate is successfully configured.

Configuration Example

Suppressing STA Roaming Syslogs

Scenario **Figure 9-7**	
Configuration Steps	● Configure the STA syslog suppression rate.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# roaming logging rate-limit 30
Verification	● After the CAPWAP tunnel is established between an AP and an AC, check the configuration information.
AC	AC# show running roaming logging rate-limit 30 !

Common Errors

- N/A

9.4.8 Preventing STA Roaming

Configuration Effect

- STAs are prevented from roaming within a WLAN.

Notes

- N/A

Configuration Steps

↘ Preventing STA Roaming within a WLAN

- (Optional) The configuration is performed on the AC. Run the **no roaming support wlan** command to prevent STA roaming.
- Roaming is permitted by default. Run the **no roaming support wlan** command to prevent STA roaming.

Command	[**no**] **roaming support wlan** *wlan-id*
Parameter Description	*wlan-id*: Specifies a WLAN.
Defaults	Roaming is permitted by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to check whether the syslog suppression rate is successfully configured.

Configuration Example

Preventing STA Roaming

Configuration Steps	• Configure roaming prevention within WLAN100.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# no roaming support wlan 100
Verification	• After the CAPWAP tunnel is established between an AP and an AC, check the configuration information.
AC	AC# show running no roaming support wlan 100 !

Common Errors

- N/A

9.5 Monitoring

Displaying

Description	Command
Displays configurations of all mobility groups.	**show mobility summary**
Displays configurations of a specified mobility group.	**show mobility status** *group-name*
Displays roaming statistics.	**show mobility statistics**
Displays roaming STA information.	**show mobility user** [*mac*]
Displays the roaming tracks of roaming STAs.	**show mobility user roam-track** *mac*

WLAN RF Configuration

1 Configuring RRM

1.1 Overview

Radio Resource Management (RRM) is an important feature running on an access controller (AC) for access point (AP) Radio Frequency (RF) management.

By analyzing the ambient RF environment of an AP in real time, RRM automatically adjusts the AP's working channel and transmit power based on a specific algorithm to avoid signal interference between APs and ensure normal operation of the wireless network.

When an AP is located in a complex RF environment, the AP may be severely interfered with. In this case, RRM can be enabled to improve user experience.

1.2 Applications

Application	Description
Centralized RRM	Multiple ACs constitute an RF group to provide centralized RRM for all APs in the entire network.

1.2.1 Centralized RRM

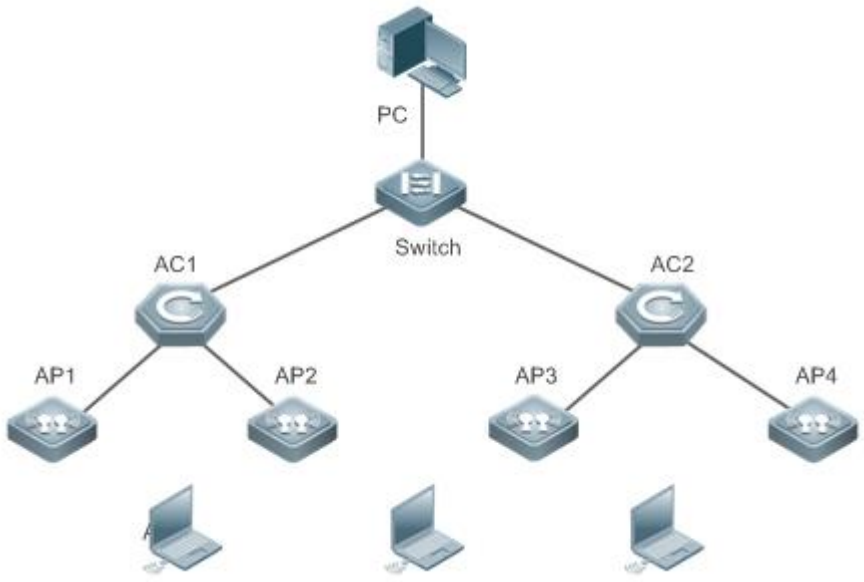
Scenario

Multiple ACs constitute an RF group to provide centralized RRM for all APs in the entire network.

Taking Figure 1-1 as an example, the clients are networked through APs which operate at the frequency band of 2.4 GHz. AP1, AP2, AP3 and AP4 are under centralized RRM within one RF group where Dynamic Channel Assignment (DCA) and Transmit Power Control (TPC) are enabled.

- A leader should be designated between AC1 and AC2, with the other being a member. The designated leader will implement centralized RRM.

Figure 1-1 Centralized RRM



Remarks	The switch is a core switch. AC 1 manages AP 1 and AP 2. AC 2 manages AP 3 and AP 4. AC 1 and AC 2 constitute an RF group.

Deployment

- With AC 1 being the leader and AC 2 being the member, configure AC 2 as the group member on AC 1 and configure AC 1 as the group leader on AC 2. The two ACs constitute an RF group.
- On the group leader AC 1, enable DCA and TPC to achieve centralized RRM.

1.3 Features

Basic Concepts

STA, AP and AC

STA: wireless station, a device with a wireless network interface card (WNIC), for example, a laptop or a cell phone.

AP: wireless access point, which provides wireless access for STAs.

AC: wireless controller, which is used to manage APs and provide wireless services.

RF Group

Multiple ACs constitute an RF group, with one AC designated as the leader which performs DCA and TPC for all APs.

RF Environment Information

- STA information: mainly includes STAs' Received Signal Strength Indication (RSSI) and Signal-to-Noise Ratio (SNR).
- Neighbor information: mainly includes neighboring APs' RSSI and working channels.
- Load: also known as utilization ratio, which is a percentage of the time spent by an AP in transmitting and receiving 802.11 data frames in the total time.
- Noise: noise intensity which affects normal reception of 802.11 signals. The unit is dBm.

- Interference: 802.11 signal interference and non-802.11 signal interference are included. The former comes from other APs and the latter generally comes from microwave radiations and Bluetooth devices. The unit is percentage (%).

Co-Channel Interference

When two APs close to each other are working in the same channel, co-channel interference occurs, which affects both APs' normal reception of 802.11 wireless packets.

Coverage Hole

When the transmit power of APs is so low that the AP signal strength in certain areas could not meet normal communication requirements, these areas are called coverage holes.

Overview

Feature	Description
RF Group	A leader-member relationship is established between ACs to form an RF group.
RF Environment Monitoring	The ambient RF environment of an AP is monitored in real time and the monitored data is sent to the AC for users to understand the AP's current RF environment.
DCA	The AC allocates an appropriate working channel to an AP based on the AP's ambient RF environment to reduce co-channel interference and improve user experience.
TPC	If multiple APs are close to each other and one of them features too high transmit power, the normal operation of other APs may be affected. In this case, the transmit power of the APs needs to be lowered to reduce the interference it generates.
Coverage Hole Detection and Correction	Through statistics and analysis of wireless signal characteristics, it can be determined whether a coverage hole exists. If a coverage hole exists, the transmit power can be increased for a specific AP to remedy the coverage hole.

1.3.1 RF Group

A leader-member relationship is established between ACs to form an RF group. A leader can perform centralized RRM for all APs only after the RF group is established between ACs. After an RF group including multiple ACs is established, RF resources can be assigned based on more comprehensive RF environment information, which is advantageous over a single AC.

Working Principle

ACs are connected through to establish an RF group, with the leader AC as the server and member ACs as the clients. After an RF group is established, when DCA or TPC is enabled, the leader requests each member for RF environment information. After connection, each member reports the information to the leader. The leader issues results to the members after completing algorithm execution.

Establishing an RF Group

Based on the configured IP address of the leader AC, each member AC periodically tries to establish a TCP connection with the leader AC. When a TCP connection is established, the leader queries whether the IP address of each member is on the group member list. If no, the leader cancels this connection. If yes, the TCP connection succeeds. A member sends an RF group registration request to the leader. If the registration succeeds, the leader returns a registration success

response to the member which is then successfully added to the group. Otherwise, a registration failure response is returned. The member disconnects from the leader after receiving the registration failure response.

↘ Maintaining the RF Group

When a member is successfully added to an RF group, keepalive packets are transmitted between the members and the leader periodically. When either party detects keepalive timeout, it cancels the connection. After disconnection, the member still tries to join a specified group periodically.

1.3.2 RF Environment Monitoring

APs monitor their ambient RF environment in real time and send the monitoring data to the associated AC. The RF environment information on each AP can be viewed on the AC.

Working Principle

The STA and neighbor information is obtained by APs through monitoring and analyzing wireless packets on the air interface, while the load, noise and interference information is obtained mainly by chip reading.

The AC notifies an AP to start collecting RF environment information. After information collection, the AP reports data to the AC.

1.3.3 DCA

For a single AP, DCA can prevent it from being subject to severe interference on the working channel.

For the global RF environment, reasonable channel assignment for each AP minimizes the interference among APs in the entire network and improves spectrum resource utilization and user experience.

Working Principle

If two APs close to each other work on the same channel, wireless signal conflict and interference occurs between them, which affect user experience.

DCA can comprehensively analyze all environmental factors (including neighbor information, loads, noises, and the number of STAs associated with an AP) and assign optimal working channels for all APs to solve channel conflict.

For example, if two APs work on the same channel or channels with frequency spectrum overlapped at the same time, the DCA algorithm can be used to stagger their channels to optimize the frequency spectrum.

1.3.4 TPC

TPC reduces signal interference between APs by reducing the APs' transmit power.

Working Principle

When an AP is powered on for the first time, the permissible maximum transmit power is used based on national or regional regulations. The higher the transmit power of an AP, the larger its signal coverage. If two adjacent APs have an excessive signal coverage overlap and work on the same frequency band, strong co-channel interference will be produced. TPC can determine whether the transmit power of an AP needs to be reduced or increased based on the information of each neighbor AP. When the co-channel interference between APs is too strong, if channels cannot be staggered, the only way to reduce the interference is to reduce the transmit power of both APs. When the interference is too little to ignore, the transmit power can be improved properly to enlarge signal coverage.

If DCA and TPC are both enabled, RRM considers the former first. If channels can be staggered, it is unnecessary to reduce the transmit power. Given this consideration, TPC uses the period set for DCA, and the TPC algorithm runs after the DCA algorithm.

1.3.5 Coverage Hole Detection and Correction

Through statistics and analysis of RSSI, it can be determined whether a coverage hole exists. If a coverage hole exists, you can increase the transmit power for a specific AP to correct the coverage hole.

Working Principle

Coverage Hole Detection (CHD) determines whether a coverage hole exists based on the quality of RSSI. This feature concerns only the data of STAs, and thus can operate independently on each AC.

When the SNR value of an STA is lower than a given threshold, the algorithm determines that a coverage hole exists. When the number of STAs in coverage holes exceeds a certain threshold (absolute number or proportion, which can be configured), the AC fixes coverage holes by improving the transmit power of APs.

1.4 Configuration

Configuration	Description and Command	
Configuring an RF Group	(Optional) It is used to configure an RF group that consists of multiple ACs.	
	advanced { 802.11a | 802.11b } group-leader	Configures the leader of an RF group.
	advanced { 802.11a | 802.11b } group-member	Configures a member of the RF group.
	network rf-network-name	Configures the name of an RF group.
Configuring RF Monitoring	(Optional) It is used to enable or disable RF environment monitoring and configure the monitoring parameters.	
	advanced { 802.11a | 802.11b } monitor mode	Enables RF environment monitoring.
	advanced { 802.11a | 802.11b } monitor channel-list	Configures the range of monitored channels.
	advanced { 802.11a | 802.11b } monitor coverage	Configures the period of client monitoring.
	advanced { 802.11a | 802.11b } monitor load	Configures the period of load monitoring.
	advanced { 802.11a | 802.11b } monitor noise	Configures the period of noise monitoring.
	advanced { 802.11a | 802.11b } monitor signal	Configures the period of neighbor monitoring.
Configuring DCA	(Optional) It is used to configure DCA.	
	advanced { 802.11a | 802.11b } channel global	Configures the DCA mode.
	advanced { 802.11a | 802.11b } channel add	Adds an optional channel to the DCA algorithm.
	advanced { 802.11a | 802.11b } channel delete	Deletes an optional channel from the DCA algorithm.

Configuration	Description and Command	
	advanced { 802.11a | 802.11b } channel clients	Configures the number threshold of clients using the DCA algorithm.
	advanced { 802.11a | 802.11b } channel countered-switch	Configures whether the DCA algorithm supports channel switching when an AP is countered.
	advanced { 802.11a | 802.11b } channel foreign	Configures whether interference is considered in the DCA algorithm.
	advanced { 802.11a | 802.11b } channel load	Configures whether loads are considered in the DCA algorithm.
	advanced { 802.11a | 802.11b } channel noise	Configures whether noises are considered in the DCA algorithm.
	advanced { 802.11a | 802.11b } channel pkt-loss-rate-threshold	Configures the threshold of packet-loss rate on the air interfaces used in the DCA algorithm.
	advanced { 802.11a | 802.11b } channel dca	Configures DCA parameters.
	advanced { 802.11a | 802.11b } channel update	Manually starts the DCA algorithm once.
Configuring TPC	(Optional) It is used to configure TPC parameters.	
	advanced { 802.11a | 802.11b } txpower dtpc	Enables or disables TPC.
	advanced { 802.11a | 802.11b } txpower global	Configures the TPC mode.
	advanced { 802.11a | 802.11b } txpower co-channel	Configures whether the TPC algorithm considers only neighbors on the same channel.
	advanced { 802.11a | 802.11b } txpower threshold	Configures the neighbor RSSI threshold used in the TPC algorithm.
	advanced { 802.11a | 802.11b } txpower update	Manually starts the TPC algorithm once.
Configuring Coverage Hole Detection and Correlation	(Optional) It is used to configure coverage hole detection and correction.	
	advanced { 802.11a | 802.11b } coverage	Enables or disables coverage hole detection and correction.
	advanced { 802.11a | 802.11b } coverage exception global	Configures the threshold of client failure rate used in the Coverage Hole Detection (CHD) algorithm.
	advanced { 802.11a | 802.11b } coverage level global	Configures the threshold of failed client number used in the CHD algorithm.
	advanced { 802.11a | 802.11b } coverage fail-rate	Configures the threshold of data or voice packet failure rate used in the CHD algorithm.
	advanced { 802.11a | 802.11b } coverage packet-count	Configures the threshold of failed data or voice packet number used in the CHD algorithm.

Configuration	Description and Command	
	advanced { 802.11a | 802.11b } coverage profile	Configures the SNR threshold of clients in a coverage hole used in the CHD algorithm.
	advanced { 802.11a | 802.11b } coverage rssi-threshold	Configures the RSSI threshold of data or voice packets used in the CHD algorithm.
Configuring RRM Logging	(Optional) It is used to configure the RRM logging feature.	
	advanced { 802.11a | 802.11b } logging channel	Enables or disables DCA logging.
	advanced { 802.11a | 802.11b } logging txpower	Enables or disables TPC logging.
	advanced { 802.11a | 802.11b } logging coverage	Enables or disables logging on over-limit AP clients.
	advanced { 802.11a | 802.11b } logging foreign	Enables or disables logging on over-limit AP interference.
	advanced { 802.11a | 802.11b } logging load	Enables or disables logging on over-limit AP loads.
	advanced { 802.11a | 802.11b } logging noise	Enables or disables logging on over-limit AP channel noises.
	advanced { 802.11a | 802.11b } logging performance	Enables or disables logging on over-limit AP performance.
	advanced { 802.11a | 802.11b } profile clients	Configures the alarm threshold of the AP client number.
	advanced { 802.11a | 802.11b } profile foreign	Configures the alarm threshold of AP interference.
	advanced { 802.11a | 802.11b } profile noise	Configures the alarm threshold of AP channel noises.
	advanced { 802.11a | 802.11b } profile throughput	Configures the alarm threshold of AP data throughput.
	advanced { 802.11a | 802.11b } profile utilization	Configures the alarm threshold of AP utilization.

1.4.1 Configuring an RF Group

Configuration Effect

- Use multiple ACs to form an RF group and choose a leader AC to uniformly implement DCA and TPC.

Notes

- If an AC is not included as a member in any RF group, this AC takes itself as the leader by default to independently manage RF resources of its associated APs.
- If an AC is configured as the group leader, it cannot be configured as a member, and vice versa.
- The first IP address of the local Loopback0 interface is used for the communication between ACs in an RF group.

Configuration Steps

Configuring an RF Group

- (Optional) Configure an RF group with multiple ACs and specify one AC as the leader to implement centralized management on RF resources (including AP channels and transmit power).
- Specify one AC as the group leader, add an IP list of admissible members on this AC, and configure the IP address of the group leader on member ACs.
- Run the **advanced** { **802.11a** | **802.11b** } **group-member** command to configure IP addresses of the member ACs. To specify one AC as the group leader, a member IP list needs to be configured on this AC. Only ACs on the member IP list can be added to the RF group.
- Run the **advanced** { **802.11a** | **802.11b** } **group-leader** command to specify an IP address as the RF group leader.
- Run the **network rf-network-name** command to configure the RF group name.

By default, an AC takes itself as the group leader to independently manage RF resources of its associated APs.

Command	**advanced** { **802.11a**	**802.11b** } **group-member** *ip-address*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *ip-address*: IP address of an RF group member
Defaults	No RF group member is configured.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a**	**802.11b** } **group-leader** *ip-address*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *ip-address*: IP address of an RF group leader
Defaults	An AC takes itself as the RF group leader to independently manage RF resources of its associated APs.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**network rf-network-name** *group-name*
Parameter Description	*group-name*: RF group name
Defaults	The default group name is rf-network
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show advanced** { **802.11a** | **802.11b** } **group** command on the leader AC and member ACs respectively to verify the established RF group.

Configuration Example

Establishing an RF Group with Two ACs

Scenario **Figure 1-2**	Configuration Steps	● Configure the Loopback0 addresses of AC1 and AC2 as 192.168.1.2 and 192.168.1.3 respectively, and ensure that the ping command is successful between the two ACs. ● Take AC1 as the RF group leader and add a member whose IP address is 192.168.1.3 on AC1. Take AC2 as a member and add the IP address 192.168.1.2 of the group leader on AC2.
AC1	AC1#configure terminal AC1(config)#interface loopback 0 AC1(config-if-Loopback 0)#ip address 192.168.1.2 255.255.255.0 AC1(config-if-Loopback 0)#exit AC1(config)#advanced 802.11b group-member 192.168.1.3 AC1(config)#exit
AC2	AC2#configure terminal AC2(config)#interface loopback 0 AC2(config-if-Loopback 0)#ip address 192.168.1.3 255.255.255.0 AC2(config-if-Loopback 0)#exit AC2(config)#advanced 802.11b group-leader 192.168.1.2 AC2(config)#exit
Verification	View the RF group status on AC1 and AC2 respectively to determine whether the RF group is successfully established.
AC1	AC1#show advanced 802.11b group RF Group Information Radio Type ..... 802.11b RF Group Name ..... rf-network I'm leader ..... yes

	Group member ..... 192.168.1.3 (connected) Last Run ..... 15 seconds ago
AC2	AC2#show advanced 802.11b group RF Group Information Radio Type ..... 802.11b RF Group Name ..... rf-network I'm leader ..... no Group leader ..... 192.168.1.2 (connected) Last Run ..... 15 seconds ago

Common Errors

- The network between ACs is blocked, which causes failed RF grouping.
- The IP address of the group leader is configured on a member, but the IP address of the member is not added on the leader, which causes failed RF grouping.
- The RF group is named inconsistently, which causes failed RF grouping.

1.4.2 Configuring RF Environment Monitoring

Configuration Effect

- A target AP's RF environment information can be viewed on the AC.

Notes

- N/A

Configuration Steps

RF Environment Monitoring

- (Optional) Configure RF environment monitoring to view a target AP's RF environment information.
- Enable RF environment monitoring on an AC and specify the monitoring period for each indicator.
- Run the **advanced** { **802.11a** | **802.11b** } **monitor mode** { **enable** | **disable** } command to enable or disable RF environment monitoring. Because the collection of RF environment information takes up a small portion of an AP's normal operation time, enabling RF environment monitoring slightly reduces AP performance.
- Run the **advanced** { **802.11a** | **802.11b** } **monitor channel-list** command to configure the range of monitored channels.
- Run the **advanced** { **802.11a** | **802.11b** } **monitor coverage** command to configure the period of client monitoring.
- Run the **advanced** { **802.11a** | **802.11b** } **monitor load** command to configure the period of load monitoring.
- Run the **advanced** { **802.11a** | **802.11b** } **monitor noise** command to configure the period of noise monitoring.
- Run the **advanced** { **802.11a** | **802.11b** } **monitor signal** command to configure the period of neighbor monitoring.

Command	**advanced** { **802.11a** | **802.11b** } **monitor mode** { **enable** | **disable** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **enable**: Enables RF environment monitoring. **Disable**: Disables RF environment monitoring.
Defaults	RF environment monitoring is disabled.
Command Mode	Global configuration mode.
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **monitor channel-list** { **all** | **country** | **dca** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **all**: Monitors all channels. **country**: Monitors channels within a specified country. **dca**: Monitors channels used by the DCA algorithm.
Defaults	The default value is **country**.
Command Mode	Global configuration mode.
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **monitor coverage** *interval*
Parameter Description	**802.11a**: 5 GHz network. **802.11a**: 2.4 GHz network. *interval*: Specifies the period of client monitoring.
Defaults	The period of client monitoring is 180 seconds.
Command Mode	Global configuration mode.
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **monitor load** *interval*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *interval*: Specifies the period of load monitoring
Defaults	The period of load monitoring is 60 seconds.
Command Mode	Global configuration mode.
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **monitor noise** *interval*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *interval*: Specifies the period of noise monitoring.

Defaults	The period of noise monitoring is 180 seconds.
Command Mode	Global configuration mode.
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **monitor signal** *interval*
Parameter Description	**802.11a**: 5 GHz network. **802.11a**: 2.4 GHz network. *interval*: Specifies the period of neighbor monitoring.
Defaults	The period of neighbor monitoring is 180 seconds.
Command Mode	Global configuration mode.
Usage Guide	N/A

Verification

- Run the **show advanced** { **802.11a** | **802.11b** } **monitor** command to display RF environment monitoring parameters.
- Run the **show ap auto-rf** command to display AP RF environment information.

Configuration Example

Enabling RF Environment Monitoring

Configuration Steps	Enable RF environment monitoring.
AC	`AC#configure terminal` `AC(config)#advanced 802.11b monitor mode enable` `AC(config)#exit`
Verification	Run the **show ap auto-rf radio** *radio-id ap-name* command to display AP RF environment information on the target AC.

Common Errors

- N/A

1.4.3 Configuring DCA

Configuration Effect

- Enable DCA on an AC so that the AC can assign appropriate working channels for APs based on AP RF environment information improving user experience.

Notes

- Normally, it is not recommended to set the period of DCA too short. By default, DCA is performed once every 20 minutes.
- If an AC joins an RF group as a member, the working channel of this member will be adjusted by the uniform channel assignment on the leader AC.
- If a channel is manually configured on an AP, DCA will not be conducted for this AP.

Configuration Steps

Configuring DCA

- (Optional) Configure DCA to automatically assign proper working channels for APs.
- Enable DCA on the target AC and configure its running mode as periodic mode or trigger mode based on your demand.
- Run the **advanced** { **802.11a** | **802.11b** } **channel global** command to configure the DCA mode. By default, DCA is running in AUTO mode.

DCA has three running modes: AUTO, ONCE and OFF. AUTO is the periodic mode in which the AC periodically assigns proper working channels for all APs. ONCE is the trigger mode in which the AC usually performs channel assignment once when the AP and AC are connected for the first time. When the channel property of the AP changes from Manual to Global, channel assignment is triggered once again. OFF is the disabled mode in which the AC does not perform DCA for APs.

- Run the **advanced** { **802.11a** | **802.11b** } **channel** { **add** | **delete** } command to add or delete an optional channel to or from DCA.
- Run the **advanced** { **802.11a** | **802.11b** } **channel clients** command to configure the number threshold of clients using the DCA algorithm.
- Run the **advanced** { **802.11a** | **802.11b** } **channel countered-switch** command to configure whether the DCA algorithm supports channel switching when an AP is countered.
- Run the **advanced** { **802.11a** | **802.11b** } **channel foreign** command to configure whether interference is considered in the DCA algorithm.
- Run the **advanced** { **802.11a** | **802.11b** } **channel noise** command to configure whether noises are considered in the DCA algorithm.
- Run the **advanced** { **802.11a** | **802.11b** } **channel pkt-loss-rate-threshold** command to configure the threshold of packet-loss rate on the air interfaces used in the DCA algorithm.
- Run the **advanced** { **802.11a** | **802.11b** } **channel dca anchor-time** command to configure when the DCA algorithm is enabled and ends within a day.
- Run the **advanced** { **802.11a** | **802.11b** } **channel dca chan-width-11n** command to configure the frequency bandwidth used by the DCA algorithm in an 802.11n network.
- Run the **advanced** { **802.11a** | **802.11b** } **channel dca interval** command to configure the running period for the DCA algorithm, which takes effect only when DCA is configured to the AUTO mode. The shorter the cycle, the faster the AP channel assignment. APs are required to scan ambient RF environment information before channel assignment, and some air interface resources will be occupied; therefore, it is normally not recommended to set the assignment period too short.

- Run the **advanced** { **802.11a** | **802.11b** } **channel dca period** command to configure the running time of the DCA algorithm within a week.
- Run the **advanced** { **802.11a** | **802.11b** } **channel dca sensitivity** command to configure the sensitivity of the DCA algorithm.
- Run the **advanced** { **802.11a** | **802.11b** } **channel update** command to manually start the DCA algorithm once.

Command	**advanced** { **802.11a**	**802.11b** } **channel global** { **auto**	**off**	**once** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **auto**: Periodic mode. **once**: Trigger mode. **off**: Disabled mode.
Defaults	DCA runs in periodic mode (AUTO).
Command Mode	Global configuration mode.
Usage Guide	In periodic mode, appropriate working channels are assigned to APs periodically, while in trigger mode, the working channel assignment is conducted once only when an AP is online for the first time or the AP's channel property is modified from Manual to Global.

Command	**advanced** { **802.11a**	**802.11b** } **channel** { **add**	**delete** } *channel-id*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **add**: Adds an optional channel to DCA. **delete**: Deletes an optional channel from DCA. *channel-id*: Channel ID
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a**	**802.11b** } **channel clients** *clients-num*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *clients-num*: Specifies the number threshold of clients using the DCA algorithm.
Defaults	The default value is 0, which means that channel assignment is not conducted when clients are associated with an AP.
Command Mode	Global configuration mode
Usage Guide	Channel switching may lead to user re-association; therefore, when the number of users associated with an AP exceeds this threshold, channel assignment will not be conducted for this AP.

Command	**advanced** { **802.11a**	**802.11b** } **channel countered-switch** { **enable**	**disable** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network

	enable: Enables channel switching when an AP is countered. **disable**: Disables channel switching when an AP is countered.
Defaults	Channel switching is disabled when an AP is countered.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **channel foreign** { **enable** | **disable** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **enable**: Considers AP interference in the DCA algorithm. **disable**: Ignores AP interference in the DCA algorithm.
Defaults	AP interference is considered in the DCA algorithm.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **channel noise** { **enable** | **disable** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **enable**: Considers noise factors in the DCA algorithm. **Disable**: Ignores noise factors in the DCA algorithm.
Defaults	Noise factors are considered in the DCA algorithm.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **channel pkt-loss-rate-threshold** *threshold*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *threshold*: Specifies the threshold of packet-loss rate on the air interfaces used in the DCA algorithm.
Defaults	The default value is 100, which means that the packet-loss rate on the air interfaces is ignored in the DCA algorithm.
Command Mode	Global configuration mode
Usage Guide	When the DCA algorithm conducts channel selection, if the packet-loss rate on the air interfaces for the current working channel is found to exceed the threshold, channel switching will be conducted.

Command	**advanced** { **802.11a** | **802.11b** } **channel dca anchor-time** *start duration*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *start*: Specifies the time when the DCA algorithm starts running in a day. The unit is hour and the value ranges from 0 to 23. *duration*: Specifies the time duration when the DCA algorithm keeps running. The unit is hour and the

	value ranges from 1 to 24.
Defaults	The default value of start-hour is 2 and that of duration is 2, meaning that the DCA algorithm runs from 2:00 am to 4:00 am.
Command Mode	Global configuration mode
Usage Guide	When the DCA algorithm is set to run in periodic mode, DCA is conducted only in this time frame. For example, if DCA is expected to run from 2:00 am to 4:00 am, you can run the **advanced** { **802.11a** | **802.11b** } **channel dca anchor-time 2 2** command.

Command	**advanced** { **802.11a** | **802.11b** } **channel dca chan-width-11n** { **20** | **40** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **20**: Uses 20 MHz bandwidth **40**: Uses 40 MHz bandwidth
Defaults	20 MHz bandwidth is used.
Command Mode	Global configuration mode
Usage Guide	20 MHz or 40 MHz bandwidth are supported.

Command	**advanced** { **802.11a** | **802.11b** } **channel dca interval** *interval*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *interval*: Period of the DCA algorithm
Defaults	The DCA algorithm runs once every 20 minutes.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **channel dca period** *day1* **to** *day2*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *day1*: Specifies which day of a week the DCA algorithm starts on. *day2*: Specifies which day of a week the DCA algorithm stops on (including that day).
Defaults	The DCA algorithm runs throughout a week, from Sunday to Saturday.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **channel dca sensitivity** { **low** | **medium** | **high** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **low**: The DCA algorithm is not very sensitive to algorithm environment change. **medium**: The DCA algorithm is of medium sensitivity to RF environment change. **high**: The DCA algorithm is very sensitive to RF environment change.

Defaults	The DCA algorithm is of medium sensitivity to RF environment change.
Command Mode	Global configuration mode.
Usage Guide	Higher sensitivity means faster channel assignment.

Command	**advanced** { **802.11a** | **802.11b** } **channel update**
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network
Defaults	**N/A**
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show advanced** { **802.11a** | **802.11b** } **channel** command to display DCA status.
- Run the **show ap-config summary** command to display the channel assignment result of an AP.

Configuration Example

Configuring the DCA Parameters

Configuration Steps	Configure DCA in periodic mode and set the period to 30 minutes.
AC	`AC#configure terminal` `AC(config)#advanced 802.11b channel global auto` `AC(config)#advanced 802.11b channel dca interval 30` `AC(config)#exit`
Verification	Display DCA status.
AC	`AC#show advanced 802.11b channel` `Automatic Channel Assignment` `Radio Type..... 802.11b` `Channel Assignment Mode..... AUTO` `Channel Update Interval..... 1800 seconds` `Periodic Motion (Day of A Week)..... All days` `Anchor Time (Hour of The Day)..... 2` `The Duration of DCA (By Hour)..... 2` `Consider Foreign Factor..... yes` `Consider Load Factor..... no`

```
Consider Noise Factor..... no
Switch Channel When Countered..... disable
Packet Loss Rate Threshold.....100%
Clients Threshold..... 0 client
Channel Assignment Leader..... 192.168.1.2
Last Run..... 263 seconds ago
DCA Sensitivity Level..... MEDIUM (15 dB)
DCA 802.11n Channel Width..... 20 MHz
Auto-RF Allowed Channel List..... 1,6,11
Auto-RF Unused Channel List..... 2,3,4,5,7,8,9,10,12,13
```

Common Errors

- If an AP has been manually assigned a channel, DCA will not be conducted for this AP.

1.4.4 Configuring TPC

Configuration Effect

- After TPC is enabled, the AC configures proper transmit power for APs based on the APs' RF environment information to reduce the co-channel interference between the APs.

Notes

- TPC is aimed at reducing the co-channel interference caused by an AP to other APs, and therefore, the TPC algorithm needs to realize the degree of co-channel interference from other APs to determine whether power control is required. Currently, TPC is supported on Ruijie APs only. If these APs are associated with multiple ACs, the ACs need to be in the same RF group.

Configuration Steps

Configuring TPC

- (Optional) Configure TPC to automatically control the transmit power of APs to avoid intensive interference between these APs.
- Enable TPC on the target AC, and configure it to run in periodic mode, trigger mode or constant power mode based on your demand.
- Run the **advanced** { **802.11a** | **802.11b** } **txpower dtpc** { **enable** | **disable** } command to enable or disable TPC.
- Run the **advanced** { **802.11a** | **802.11b** } **txpower global** command to configure the TPC mode.

TPC has three running modes: constant power mode, periodic mode (AUTO) and trigger mode (ONCE). In constant power mode, a power level is manually specified for each AP connected to the AC, with level 1 being the highest transmit power and level 8 being the lowest transmit power, and the transmit power on a level is 50% of that on the next level, with the level ranging from 1 to 8; in periodic mode (AUTO), the AC periodically conducts TPC for all APs; in trigger mode (ONCE), power control is conducted once only when an AP is connected with the AC for the first time or when the AP's power property changes from Manual to Global.

- Run the **advanced** { **802.11a** | **802.11b** } **txpower co-channel** command to configure whether the TPC algorithm considers only neighbors on the same channel.
- Run the **advanced** { **802.11a** | **802.11b** } **txpower threshold** command to configure the threshold of neighbor RSSI used in the TPC algorithm.
- Run the **advanced** { **802.11a** | **802.11b** } **txpower update** command to manually start the TPC algorithm once.

Command	**advanced** { **802.11a**	**802.11b** } **txpower dtpc** { **enable**	**disable** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **enable**: enables TPC **disable**: disables TPC
Defaults	TPC is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a**	**802.11b** } **txpower global** { **auto**	**once**	*power-level* }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **auto**: Periodic mode. **once**: Trigger mode. *level*: Specifies power levels for all APs, ranging from 1 to 8, with a smaller value indicating a higher power level.
Defaults	TPC runs in periodic mode (AUTO).
Command Mode	Global configuration mode
Usage Guide	The parameters configured with this command take effect only when TPC is enabled. The TPC algorithm runs after the DCA algorithm, and therefore, the period set for DCA is used.

Command	**advanced** { **802.11a**	**802.11b** } **txpower co-channel** { **enable**	**disable** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **enable**: Only neighbor APs on the same channel are considered in the TPC algorithm. **disable**: All neighbor APs are considered in the TPC algorithm.
Defaults	All neighbor APs are considered in the TPC algorithm.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a**	**802.11b** } **txpower threshold** *value*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network

	value: Specifies the threshold of neighbor RSSI, ranging from -90 dBm to -50 dBm
Defaults	The threshold of neighbor RSSI is -60 dBm.
Command Mode	Global configuration mode
Usage Guide	The smaller the neighbor RSSI threshold, the easier the power control is triggered to reduce an AP's transmit power.

Command	**advanced** { **802.11a** | **802.11b** } **txpower update**
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network
Defaults	**N/A**
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show advanced** { **802.11a** | **802.11b** } **txpower** command to display TPC status.
- Run the **show ap-config summary** command to display the power control result of an AP.

Configuration Example

Configuring TPC Parameters

Configuration Steps	Enable TPC and configure it to run in periodic mode.
AC	`AC#configure terminal` `AC(config)#advanced 802.11b txpower dtpc enable` `AC(config)#advanced 802.11b txpower global auto` `AC(config)#exit`
Verification	Display TPC status.
AC	`AC#show advanced 802.11b txpower` `Automatic Transmit Power Assignment` `Radio Type..... 802.11b` `Dynamic Transmit Power Control Support..... enable` `Transmit Power Assignment Mode..... AUTO` `Transmit Power Update Interval..... 1800 seconds` `Consider The Same Channel Neighbor Only..... No` `Transmit Power Threshold..... -60 dBm`

	Transmit Power Neighbor Count..... 3 APs Transmit Power Assignment Leader..... 192.168.1.2 Last Run..... 568 seconds ago

Common Errors

- If an AP is manually assigned a power level, TPC will not be conducted for this AP.

1.4.5 Configuring Coverage Hole Detection and Correction

Configuration Effect

- After coverage hole detection and correction is enabled, the AC determines whether an AP has a coverage hole. If yes, the AP's transmit power will be increased to correct the coverage hole.

Notes

- The coverage hole detection and correction feature needs only statistic information on STAs associated with this AP, and therefore, it can operate independently on a single AC and is independent of any RF group.

Configuration Steps

↘ Configuring Coverage Hole Detection and Correction

- (Optional) Configure coverage hole detection and correction to enable APs to actively detect and correct coverage holes.
- Run the **advanced** { **802.11a** | **802.11b** } **coverage** { **enable** | **disable** } command to enable or disable coverage hole detection and correction.
- Run the **advanced** { **802.11a** | **802.11b** } **coverage exception global** command to configure the threshold of client failure rate used in the CHD algorithm.
- Run the **advanced** { **802.11a** | **802.11b** } **coverage level global** command to configure the threshold of failed client number used in the CHD algorithm.
- Run the **advanced** { **802.11a** | **802.11b** } **coverage** { **data** | **voice** } **fail-rate** command to configure the threshold of data or voice packet failure rate used in the CHD algorithm.
- Run the **advanced** { **802.11a** | **802.11b** } **coverage** { **data** | **voice** } **packet-count** command to configure the threshold of failed data or voice packet number used in the CHD algorithm.
- Run the **advanced** { **802.11a** | **802.11b** } **coverage profile** command to configure the SNR threshold of clients in a coverage hole used in the CHD algorithm.
- Run the **advanced** { **802.11a** | **802.11b** } **coverage** { **data** | **voice** } **rssi-threshold** command to configure the RSSI threshold of data or voice packets used in the CHD algorithm.

Command	**advanced** { **802.11a**	**802.11b** } **coverage** { **enable**	**disable** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **enable**: Enables coverage hole detection and correction. **disable**: Disables coverage hole detection and correction.

Defaults	Coverage hole detection and correction is enabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **coverage exception global** *percent*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *percent*: Specifies the threshold percentage of failed clients, ranging from 1 to 100.
Defaults	The default value is 25.
Command Mode	Global configuration mode
Usage Guide	The smaller the value is, the easier the coverage hole correction is triggered to increase APs' transmit power.

Command	**advanced** { **802.11a** | **802.11b** } **coverage level global** *clients-num*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *clients-num*: Specifies the threshold of failed client number, ranging from 1 to 75.
Defaults	The default value is 3.
Command Mode	Global configuration mode
Usage Guide	The smaller the value is, the easier the coverage hole correction is triggered to increase APs' transmit power.

Command	**advanced** { **802.11a** | **802.11b** } **coverage** { **data** | **voice** } **fail-rate** *percent*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **data**: Specifies the threshold for data packets. **voice**: Specifies the threshold for voice packets. *percent*: Specifies the threshold percentage of failed packets, ranging from 1 to 100.
Defaults	The default value is 20.
Command Mode	Global configuration mode
Usage Guide	The smaller the value is, the easier the coverage hole correction is triggered to increase APs' transmit power.

Command	**advanced** { **802.11a** | **802.11b** } **coverage** { **date** | **voice** } **packet-count** *packets*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **data**: Specifies the threshold for data packets.

	voice: Specifies the threshold for voice packets. *percent*: Specifies the threshold number of failed packets, ranging from 1 to 255.
Defaults	The default value is 10.
Command Mode	Global configuration mode
Usage Guide	The smaller the value is, the easier the coverage hole correction is triggered to increase APs' transmit power.

Command	**advanced** { **802.11a** | **802.11b** } **coverage profile** *value*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network *value*: SNR threshold of clients in a coverage hole, ranging from 1 dB to 30 dB.
Defaults	The default value for a 5 GHz network is 16 dB, and the default value for a 2.4 GHz network is 12 dB.
Command Mode	Global configuration mode
Usage Guide	The smaller the value is, the easier the coverage hole correction is triggered to increase APs' transmit power.

Command	**advanced** { **802.11a** | **802.11b** } **coverage** { **data** | **voice** } **rssi-threshold** *value*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **data**: Specifies the threshold for data packets. **voice**: Specifies the threshold for voice packets. *value*: RSSI threshold, ranging from -90 to -60 .
Defaults	The default value for data packets is -80 dBm, and the default value for voice packets is -75 dBm.
Command Mode	Global configuration mode
Usage Guide	The smaller the value is, the easier the coverage hole correction is triggered to increase APs' transmit power.

Verification

- Run the **show advanced** { **802.11a** | **802.11b** } **coverage** command to display the status of coverage hole detection and correction.
- Run the **show ap-config summary** command to display the power change result of an AP.

Configuration Example

Configuring Coverage Hole Detection and Correction

Configuration Steps	Enable coverage hole detection and correction.
AC	`AC#configure terminal`

	AC(config)#advanced 802.11b coverage enable AC(config)#exit
Verification	Display the status of coverage hole detection and correction.
AC	AC#show advanced 802.11b coverage Coverage Hole Detection Radio Type..... 802.11b Coverage Hole Detection Mode..... enable Coverage Voice Packet Count..... 10 packets Coverage Voice Packet Percentage..... 20% Coverage Voice RSSI Threshold..... -75 dBm Coverage Data Packet Count..... 10 packets Coverage Data Packet Percentage..... 20% Coverage Data RSSI Threshold..... -80 dBm Global Coverage Exception Level..... 25% Global Client Minimum Exception Level..... 3 clients Global Coverage Profile Value..... 12 dB

Common Errors

- If a power level has been manually specified for an AP, CHD will not increase the AP's transmit power.

1.4.6 Configuring RRM Logging

Configuration Effect

- Enable RRM logging to print RRM logs on the target AC.

Notes

- If an AC manages too many APs, enabling RRM logging may cause too much information to be printed.

Configuration Steps

↘ Enabling or Disabling RRM Logging

- (Optional) Enable RRM logging to view RRM logs on the target AC.
- RRM logging provides log classification, allowing you to enable or disable certain logs on the AC.
- Run the **advanced** { **802.11a** | **802.11b** } **logging channel** { **on** | **off** } command to enable or disable DCA logging.
- Run the **advanced** { **802.11a** | **802.11b** } **logging txpower** { **on** | **off** } command to enable or disable TPC logging.
- Run the **advanced** { **802.11a** | **802.11b** } **logging coverage** { **on** | **off** } command to enable or disable the logging on over-limit AP clients.

- Run the **advanced** { **802.11a** | **802.11b** } **logging load** { **on** | **off** } command to enable or disable logging on over-limit AP loads.
- Run the **advanced** { **802.11a** | **802.11b** } **logging performance** { **on** | **off** } command to enable or disable logging on over-limit AP data throughput.
- Run the **advanced** { **802.11a** | **802.11b** } **logging foreign** { **on** | **off** } command to enable or disable logging on over-limit AP interference.
- Run the **advanced** { **802.11a** | **802.11b** } **logging noise** { **on** | **off** } command to enable or disable logging on over-limit AP channel noises.

Command	**advanced** { **802.11a**	**802.11b** } **logging channel** { **on**	**off** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **on**: Enables logging. **off**: Disables logging.
Defaults	Logging is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a**	**802.11b** } **logging txpower** { **on**	**off** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **on**: Enables logging. **off**: Disables logging.
Defaults	Logging is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a**	**802.11b** } **logging coverage** { **on**	**off** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **on**: Enables logging. **off**: Disables logging.
Defaults	Logging is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a**	**802.11b** } **logging load** { **on**	**off** }
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **on**: Enables logging. **off**: Disables logging.

Defaults	Logging is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**advanced** { **802.11a** | **802.11b** } **logging performance** { **on** | **off** }

Configuring RRM Alarm Thresholds

- (Optional) Alarm thresholds can be configured to trigger RRM logging on the target AC.
- Alarm thresholds can be configured to monitor various data (including the number of STAs associated with an AP, load, throughput, interference, and noise) on the target AC. If an indicator exceeds the set alarm threshold and the corresponding logging is enabled, RRM log printing is triggered.
- Run the **advanced** { **802.11a** | **802.11b** } **profile clients** command to configure the alarm threshold of the AP client number.
- Run the **advanced** { **802.11a** | **802.11b** } **profile utilization** command to configure the alarm threshold of AP loads.

- Run the **advanced** { **802.11a** | **802.11b** } **profile throughput** command to configure the alarm threshold of AP data throughput.
- Run the **advanced** { **802.11a** | **802.11b** } **profile foreign** command to configure the alarm threshold of AP interference.
- Run the **advanced** { **802.11a** | **802.11b** } **profile noise** command to configure the alarm threshold of AP channel noises.

Command	**advanced** { **802.11a**	**802.11b** } **profile clients** { **global**	*ap-name* } *clients-num*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **global**: Global alarm threshold *ap-name*: Alarm threshold for a specified AP *clients-num*: Alarm threshold of the number of clients
Defaults	The default value is 32.
Command Mode	Global configuration mode
Usage Guide	If an AP's alarm threshold of the number of clients is specified, the global alarm threshold will not be used.

Command	**advanced** { **802.11a**	**802.11b** } **profile utilization** { **global**	*ap-name* } *percent*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **global**: Global alarm threshold *ap-name*: Alarm threshold for a specified AP *percent*: Load alarm threshold
Defaults	The default value of *percent* is 80%.
Command Mode	Global configuration mode
Usage Guide	If an AP's alarm threshold is specified, the global alarm threshold will not be used.

Command	**advanced** { **802.11a**	**802.11b** } **profile throughput** { **global**	*ap-name* } *value*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **global**: Global alarm threshold *ap-name*: Alarm threshold for a specified AP *value*: alarm Threshold of AP data throughput
Defaults	The default *value* is 150,000,000 bps.
Command Mode	Global configuration mode
Usage Guide	If an AP's alarm threshold is specified, the global alarm threshold will not be used.

Command	**advanced** { **802.11a**	**802.11b** } **profile foreign** { **global**	*ap-name* } *percent*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network

	global: Global alarm threshold *ap-name*: Alarm threshold for a specified AP *percent*: Alarm threshold of AP interference
Defaults	The default *percent* is 60%.
Command Mode	Global configuration mode
Usage Guide	If an AP's alarm threshold is specified, the global alarm threshold will not be used.

Command	**advanced** { **802.11a** | **802.11b** } **profile noise** { **global** | *ap-name* } *value*
Parameter Description	**802.11a**: 5 GHz network **802.11a**: 2.4 GHz network **global**: Global alarm threshold *ap-name*: Alarm threshold for a specified AP *value*: Alarm threshold of channel noises
Defaults	The default *value* is -70 dBm.
Command Mode	Global configuration mode
Usage Guide	If an AP's alarm threshold is specified, the global alarm threshold will not be used.

Verification

- Run the **show advanced** { **802.11a** | **802.11b** } **logging** command to check whether RRM logging is enabled.
- Run the **show advanced** { **802.11a** | **802.11b** } **profile** command to check the configured alarm thresholds.
- Observe whether RRM logs are printed on the target AC in a period of time.

Configuration Example

Configuring RRM Logging

Configuration Steps	Enable DCA and TPC logging.
AC	AC#configure terminal AC(config)#advanced 802.11b logging channel on AC(config)#advanced 802.11b logging txpower on AC(config)#exit
Verification	Display RRM logging information.
AC	AC#show advanced 802.11b logging RF Event and Performance Logging Radio Type..... 802.11b Channel Update Logging..... On

```
TxPower Update Logging..... On
Coverage Profile Logging..... Off
Foreign Profile Logging..... Off
Load Profile Logging..... Off
Noise Profile Logging..... Off
Performance Profile Logging..... Off
```

Common Errors

- N/A

1.5 Monitoring

Displaying

Description	Command
Displays RF group status.	**show advanced** { **802.11a** | **802.11b** } **group**
Displays RF environment monitoring status.	**show advanced** { **802.11a** | **802.11b** } **monitor**
Displays the RF environment information of an AP.	**show ap auto-rf radio** *radio-id ap-name*
Displays DCA status.	**show advanced** { **802.11a** | **802.11b** } **channel**
Displays TPC status.	**show advanced** { **802.11a** | **802.11b** } **txpower**
Displays the status of coverage hole detection and correction.	**show advanced** { **802.11a** | **802.11b** } **coverage**
Displays whether RRM logging is enabled.	**show advanced** { **802.11a** | **802.11b** } **logging**
Displays RRM alarm thresholds.	**show advanced** { **802.11a** | **802.11b** } **profile**
Displays AP channels and transmit power.	**show advanced** { **802.11a** | **802.11b** } **summary**

2 Configuring WLAN Optimization

2.1 Overview

Wireless network optimization is to optimize the wireless network and enhance the experience of wireless users by adjusting some configuration of the WLAN.

WLAN configuration can be optimized to:

- Reduce co-channel interference and adjacent-channel interference and enhance signal coverage.
- Increase the channel bandwidth.
- Improve the channel utilization rate.
- Improve the available channel bandwidth for wireless users.
- Decrease network attacks and multicast packet bandwidth usage.
- Improve the downlink throughput of the AP.
- Reduce weak-signal terminals and overall wireless network performance.
- Reduce the influence of the power-saving network adapter.
- Limit the number of access users.

Different WLAN optimization methods are applicable to different application scenarios. See the following table.

WLAN Optimization Method	Application Scenario
Channel planning and adjustment	This method is used as required.
Power planning and adjustment	This method is used as required.
Terminating low-rate applications	This method is applicable to the high-density deployment scenario (school and building).
Establishing a pure 11n wireless network	Settings shall be performed based on actual network requirements.
Adjusting Beacon sending interval	This method is applicable to the high-density deployment scenario where many service set identifiers (SSIDs) are configured for the AP.
Enabling layer 2 isolation for wireless users in a VLAN	This function must be configured for the network not requiring layer 2 mutual-access.
Enabling the RTS/CTS protection mechanism	This method is applicable to the network involving indoor coverage.
Enhancing the AP's packet sending priority and suppressing packet sending by the wireless client	It is recommended that you determine whether to use this method based on actual effects.
Reducing the influence of weak-signal terminals	This method is applicable to the high-density deployment scenario (school and building).
Band selection	This method is applicable to the high-density deployment scenario where the AP supports dual bands.
Power-saving client processing optimization	This method is applicable to all scenarios.

WLAN Optimization Method	Application Scenario
11N A-MPDU aggregation frame sending protection	This method is applicable to all scenarios.
Limiting the STA number on the AP	This method is applicable to the high-density deployment scenario (school and building) with lots of wireless users.

Protocol Specification

- IEEE Std 802.11-2012: Wireless LAN Medium Access Control (MAC) and Physical Layer (PHY) Specifications

2.2 Applications

Typical Application	Scenario
802.11n	AP and STA both support the 11n network.
WLAN Spectrum Navigation of Fit AP	Fit AP architecture. The spectrum navigation function is enabled for the WLAN composed of multiple dual-band APs.

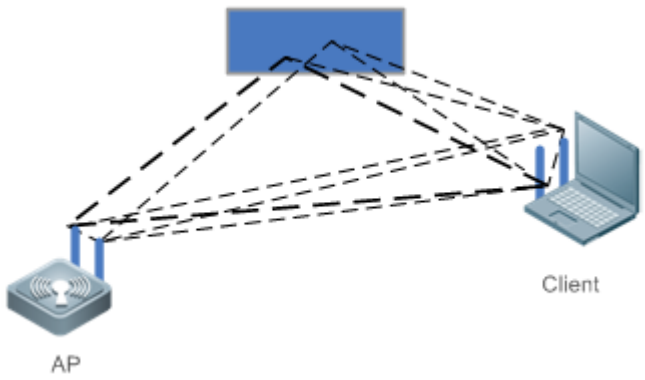
2.2.1 802.11n

Scenario

As a new protocol of the 802.11 protocol family, 802.11n supports two frequency bands, that is, 2.4 GHz and 5 GHz. It aims to provide WLAN access users with higher access rate. 802.11n improves the communication rate by using the MIMO technology or by increasing the bandwidth and improving the channel utilization rate.

As shown in Figure 2-1, the client accesses the wired network through the AP; the client and AP communicate with each other in wireless mode; and there are multiple transmission paths between the client and AP.

Figure 2-1



Remarks	AP represents a wireless access point. Client represents a wireless client.

Deployment

- Enable the IEEE802.11 protocol on the AP and Client to implement access and authentication of the wireless client.

2.2.2 Spectrum Navigation for WLAN Composed of Fit APs

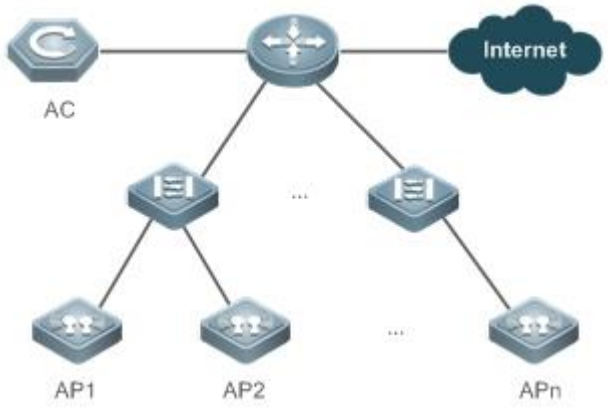
Scenario

Fit AP architecture. The spectrum navigation function is enabled for the WLAN composed of multiple dual-band APs.

As shown in Figure 2-2:

- One AC is associated with many dual-band APs. The AC and APs are connected by the layer 2 switching device and layer 3 routing device.
- WLAN is mapped to the two radio frequency (RF) interfaces of all dual-band APs.

Figure 2-2



Remarks	AC represents a wireless access controller. AP1, AP2… and APn are all dual-band APs.

Deployment

- Manage the operating parameters of the spectrum navigation function on the AC device.
- Enable the spectrum navigation function on the AP device to identify the STA type and guide STA access.

2.3 Features

Basic Concepts

WLAN

Wireless Local Area Network (WLAN) interconnects computer devices by using the wireless communication technology to form a network system that supports mutual communication and resource sharing. The essential feature of WLAN is to connect computers to the Internet in wireless mode rather than by using communication cables, facilitating network construction and terminal migration.

AP

Access Point (AP): AP is used for a wireless terminal to access the wired network. It serves as the communication bridge between a wireless terminal and wired network.

STA

Wireless user: A user who accesses the Internet by using a wireless terminal.

RSSI

Received Signal Strength Indication (RSSI) is used to indicate the quality of a wireless link.

Overview

Function and Feature	Description
Terminating Low-Rate Applications	Terminate low-rate applications by configuring the rate set.
Increasing the Beacon Frame Period Appropriately	Lengthen the Beacon frame period; reduce the frequency of sending Beacon frames; reduce the channel usage for packet management; increase the available channel bandwidth for wireless users.
Configuring Layer 2 Isolation of Wireless Users in a VLAN	Configure this function for the network not requiring layer 2 mutual-access to decrease network attacks and multicast packet bandwidth usage.
Configuring Rate Limit for Wireless Users	Make limited network resources serve more users.
Improving the Anti-Interference Capability	When there is co-channel interference, decrease the RTS threshold appropriately to improve the anti-interference capability.
Improving the Capability of Competing for Channels	Adjust the values of the EDCA parameters on the client or AP based on actual requirements to make the AC with a higher priority to start the backoff process earlier than other ACs and preferentially access the channel.
Reducing Weak-Signal Terminals	To control the network coverage of the AP and improve the transmission quality of wireless signals, limit the number of wireless access users.
Limiting the STA Access Number for an AP	Limit the STA number on the AP to implement load balancing to a certain extent, avoiding uneven distribution of AP access users.
Establishing a Pure 11n Network	Configure a pure 11n network to prohibit access of non-11n devices; make all the 11n devices to use pure HT header for transmission; reduce the size of the packet header; increase the available channel bandwidth for the wireless users.
Spectrum Navigation	Guide access of the dual-band STA to the 5G frequency band that has stronger access capacity by means of band selection to reduce the pressure of the 2.4G frequency band, thereby improving user experience.
One-Click Network Optimizaion	After the wireless network runs for a period of time, the following problems may occur: The network speed is slow. Signal or interference problems exist. The authentication page cannot be displayed. STAs equipped with 2.4 GHz/5 GHz network cards are usually associated the network at the 2.4 GHz band. A large number of low-rate packets exist. Multicast packets are lost or re-transmitted. In this case, network optimization is required.

2.3.1 Terminating Low-Rate Applications

Working Principle

Terminate low-rate applications by configuring the rate set.

2.3.2 Increasing the Beacon Frame Period Appropriately

Working Principle

Lengthen the Beacon frame period; reduce the frequency of sending Beacon frames; reduce the channel usage for packet management; increase the available channel bandwidth for wireless users.

2.3.3 Configuring Layer 2 Isolation of Wireless Users in a VLAN

Working Principle

Configure this function for the network not requiring layer 2 mutual-access to decrease network attacks and multicast packet bandwidth usage.

2.3.4 Configuring Rate Limit for Wireless Users

Working Principle

To make limited network resources serve more users, ensure that the device supports the traffic rate limit function. When the data traffic accords with the committed rate, data packets are allowed to pass. When the data traffic does not accord with the committed rate, data packets are discarded.

2.3.5 Improving the Anti-Interference Capability

Working Principle

To avoid data transmission failure caused by conflicts between channels, the IEEE 802.11 MAC protocol provides a Request to Send/Clear to Send (RTS/CTS) handshake protocol, that is, requests to send/allow sending protocol. The following description assumes that workstation A needs to send data to workstation B. First of all, workstation A sends a RTS request frame. If workstation B allows workstation A to send the request frame, workstation B replies a CTS permission frame. After receiving this permission frame, workstation A begins to sending data. If multiple workstations send RTS requests to the same workstation, only the workstations receiving CTS are allowed to send data. For the workstation not receiving CTS, it is regarded that channel conflict occurs. In this case, this workstation waits for a certain time and sends a RTS request again.

If RTS/CTS handshake needs to be performed when a workstation sends data each time, excessive RTS frames will occupy much channel bandwidth. Users can set the RTS threshold to specify the length of the data frame to be sent. RTS/CTS handshake is not performed when a workstation sends a data frame with a length smaller than the RTS threshold.

2.3.6 Improving the Capability of Competing for Channels

Working Principle

EDCA parameters differentiate access capabilities of channels with different priorities. Each AC has its own EDCA channel competition parameters. Users can adjust the values of the EDCA parameters on the client or AP based on actual requirements to make the AC with a higher priority to start the backoff process earlier than other ACs and preferentially access the channel.

During actual configuration, you can choose to configure the EDCA parameters on the client or side based on application requirements. Configuration of EDCA parameters on the client and AP respectively affects the downlink data traffic and uplink data traffic.

2.3.7 Reducing Weak-Signal Terminals

Working Principle

Wireless users search for the AP in active scanning or passive scanning mode.

- Active scanning: A wireless user sends a Probe Request for accessing the AP. After confirming the request frame, the AP returns a Probe Response frame.
- Passive scanning: The AP periodically broadcasts Beacon frames. A wireless user attempts to connect to the AP after listening Beacon frames.

To control the network coverage of the AP and improve the transmission quality of wireless signals, limit the number of wireless access users. You can control the Beacon frame broadcast coverage of the AP to prevent access of remote wireless users. You can also limit the minimum value of the RSSI for wireless users. When the RSSI of the request frame sent from a wireless user is smaller than this minimum value, the access of this wireless user is not allowed.

2.3.8 Limiting the STA Number for an AP

Working Principle

In a WLAN, one AP allows access of multiple wireless users, and the administrator can specify the maximum number of wireless users. Limit the STA access number for the AP to implement load balancing to a certain extent, avoiding uneven distribution of AP access users.

2.3.9 Establishing a Pure 11n Network

Working Principle

Configure a pure 11n network to prohibit access of non-11n devices; make all the 11n devices of the network to use pure HT header for transmission; reduce the size of the packet header; increase the available channel bandwidth for the wireless users.

2.3.10 Spectrum Navigation

Working Principle

IEEE802.11 mainly has two communication frequency bands:

- 2.4 GHz (2.412 to 2.4835 GHz) (IEEE 802.11b/g operates in this frequency range)
- 5 GHz (5.15 to 5.35 and 5.725 to 5.825 GHz) (IEEE 802.11a operates in this frequency range)

Dual-band STA supports both 2.4G and 5G frequency bands. However, users lack professional knowledge; most wireless access service vendors do not provide effective guidance; 802.11b/g is more widely applied than 802.11a. Consequently, many dual-band STAs only use the 2.4G frequency band, causing congestion of the 2.4G frequency band and waste of the 5G frequency band. In fact, the 5G frequency band has a stronger access capacity than the 2.4G frequency band: The 2.4G frequency band at most has three non-overlapping communication channels, whereas the 5G frequency band can

provide more than three non-overlapping communication channels. For example, 13 in China and up to 24 in North America.

Guide access of the dual-band STA to the 5G frequency band that has stronger access capacity by means of band selection to reduce the pressure of the 2.4G frequency band, thereby improving user experience.

2.3.11 One-Click Network Optimization

Working Principle

After the wireless network runs for a period of time, the following problems may occur:
The network speed is slow.
Signal or interference problems exist.
The authentication page cannot be displayed.

STAs equipped with 2.4 GHz/5 GHz network cards are usually associated the network at the 2.4 GHz band.
A large number of low-rate packets exist.
Multicast packets are lost or re-transmitted.
In this case, network optimization is required.

1. The network speed is slow.

The possible causes are as follows:
No rate limit is configured. Some users occupy large bandwidth for downloading or playing videos. As a result, the network speed of other users is slow.
A rate limit is configured but the rate is high, without achieving the rate limit effect.
A rate limit is configured but the rate is low, resulting in slow network speed.
For this problem, the rate limit solution can be used. Rate limiting is performed for all STAs by WLAN to ensure that the average uplink and downlink rate is 256 kbit/s and the abrupt rate is 300 kbit/s.

2. Signal or interference problems exist.

For example, the signal is poor, roaming frequently occurs, or intra-frequency/inter-frequency interference occurs. For this problem, the RRM function can be used. After the RRM function is enabled, channel or power adjustment is performed for online APs or newly added APs to ensure signal coverage and channel different from those of neighboring APs. If the poor signal or intra-frequency/inter-frequency interference problem does not exist, disable the RRM function to improve the device performance.

3. The authentication page cannot be displayed.

This is because few sessions are configured. For this problem, restore the default number of sessions to ensure that each STA supports 255 sessions and each port supports 1000 sessions by default.

4. STAs equipped with 2.4 GHz/5 GHz network cards are usually associated the network at the 2.4 GHz band.

For this problem, the 5 GHz preferred function can be used. If only few STAs supporting 5 GHz exist in the environment, it is recommended that the 5 GHz preferred function be disabled.

5. A large number of low-rate packets exist.

For this problem, the low-rate packet forbidding function can be used to forbid packets complying with 802.11b, 802.11g, or 802.11a and with a rate lower than 11 Mbps.

6. Multicast packets are lost or re-transmitted.

This is because a high multicast rate is set. For this problem, restore the default multicast rate to ensure user experience.

2.3.12 Intelligent Network Optimization

Perform wireless network optimization intelligently.

Working Principle

Perform wireless network optimization intelligently based on real-time network running.

2.3.13 Mcell Configuration

Enable dense deployment optimization.

Working Principle

Enable dense deployment optimization.

2.3.14 Roaming Stickiness

Working Principle

Monitor terminals with low RSSI and poor user experience on the entire wireless network in real time and determine whether more suitable APs exist for terminals to access the network based on the terminal detection information collected by each AP. If such terminals with sticky roaming exist, the AP sends a deauthentication frame to disassociate with the terminal to ensure that the terminal is associated with an AP with better signal quality.

2.3.15 Remote Association Information Collection

Working Principle

Determine whether a terminal is associated with the AP with the optimal signal quality based on the terminal detection information. If it is detected that a terminal associates with an AP with poor signal quality, a notification is reported to the WIS client. Based on collected remote association information, the WIS client performs coverage optimization for APs.

2.3.16 Automatic Device Information Upload

Working Principle

Configure automatic upload of the AC and AP software and hardware version numbers.

2.4 Configuration

Configuration Item	Configuration Suggestion & Relevant Command	
Configuring the Rate Set	⚠ Optional. It is used to terminate low-rate applications.	
	802.11a network rate	Configures the 11a rate set.
	802.11b network rate	Configures the 11b rate set.
	802.11g network rate	Configures the 11g rate set.

Configuring the Beacon Frame Period	Optional. It is used to increase the Beacon frame period.	
	beacon period	Configures the Beacon frame period.
Configuring Layer 2 Isolation of Wireless Users in a VLAN	Optional. It is used to enable layer 2 isolation of wireless users in a VLAN.	
	user-isolation ssid_ap enable	Configures WLAN-based user isolation for an AP.
	user-isolation ap enable	Configures user isolation for an AP.
	user-isolation ssid_ac enable	Configures WLAN-based user isolation for an AC.
	user-isolation ac enable	Configures user isolation for an AC.
Configuring Rate Limit for Wireless Users	Optional. It is used to configure rate limit for wireless users.	
	ap-based	Configures AP-based rate limit.
	netuser	Configures client-based rate limit.
	wlan-based	Configures WLAN-based rate limit.
Configuring the RTS/CTS Protection Mechanism	Optional. It is used to configure the RTS/CTS protection mechanism.	
	rts-threshold	Configures the RTS threshold.
Configuring EDCA Parameters	Optional. It is used to configure EDCA parameters.	
	wmm edca-client	Configures the EDCA parameters on the client.
	wmm edca-radio	Configures the EDCA parameters on the AP.
Configuring the Allowed Access Signal Strength	Optional. It is used to configure the allowed access signal strength.	
	response-rssi	Configures the minimum RSSI for wireless user access.
	coverage-area-control	Configures the management frame transmit power.
Configuring the Number of Access Users Allowed by the AP	Optional. It is used to configure the number of access users allowed by the AP.	
	sta-limit	Configures AP-based STA number limit.
Configuring a Pure 11n Network	Optional. It is used to configure a pure 11n network.	
	11asupport	Configures whether to support 11a or not.
	11bsupport	Configures whether to support 11b or not.
	11gsupport	Configures whether to support 11g or not.
	11nasupport	Configures whether to support 11na or not.
	11ngsupport	Configures whether to support 11ng or not.
Configuring Spectrum Navigation	Mandatory. It is used to enable the spectrum navigation function of the WLAN.	
	band-select enable	Enables the spectrum navigation function.

	⚠ Optional. It is used to configure the operating parameters of the spectrum navigation function.	
	band-select acceptable-rssi	Configures the lower limit of STA signal strength accepted by spectrum navigation.
	band-select access-denial	Configures the number of times for which dual-band STA access to 2.4G band is denied.
	band-select age-out	Configures the STA information aging time.
	band-select probe-count	Configures the detection period count of suppression STA.
	band-select scan-cycle	Configures the threshold of STA detection scanning period.
Configuring One-Click Network Optimization	⚠ Optional. It is used to configure network optimization options.	
	wopt choose	Configures network optimization options.
	⚠ Optional. It is used to configure one-click network optimization.	
	wopt enable	Configures one-click network optimization.
Configuring Intelligent Network Optimization	⚠ Optional. It is used to configure network optimization options.	
	wis enable	Enables intelligent network optimization.
Configuring mcell	⚠ Optional. It is used to configure network optimization options.	
	mcell enable	Enables dense deployment optimization.
Configuring Roaming Stickness	⚠ Optional. It is used to configure network optimization options.	
	sticky-steering monitor-only	Enables roaming stickiness monitoring.
	⚠ Optional. It is used to configure one-click network optimization.	
	sticky-steering enable	Enables roaming stickiness navigation.
Configuring Remote Association	⚠ Optional. It is used to configure network optimization options.	
	farpoint-steering enable	Enables remote association.

2.4.1 Configuring the Rate Set

Configuration Effect

- Configure the rate set to terminate low-rate applications; prohibit packet transmission at low rate between the STA and AP; improve the channel usage.

Notes

- If you disable a rate, this rate can no longer be used.
- If you disable all rates, wireless users cannot access the WLAN.

- If you disable all 11b rates, 11b wireless users cannot access the WLAN.

Configuration Steps

Configuring the 11a Rate Set

- Mandatory configuration. By default, configuration of rates 6 Mbps, 12 Mbps, and 24 Mbps is mandatory, and configuration of rates 9 Mbps, 18 Mbps, 36 Mbps, 48 Mbps, and 54 Mbps is optional.
- Unless otherwise specified, the configuration shall be performed in AC configuration mode on the AC device.

Configuring the 11b Rate Set

- Optional configuration. By default, configuration of rates 1 Mbps, 2 Mbps, 5.5 Mbps, and 11 Mbps is mandatory.
- Unless otherwise specified, the configuration shall be performed in AC configuration mode on the AC device.

Configuring the 11g Rate Set

- Optional Configuration. By default, configuration of rates 1 Mbps, 2 Mbps, 5.5 Mbps, and 11 Mbps is mandatory, and configuration of rates 6 Mbps, 9 Mbps, 12 Mbps, 18 Mbps, 24 Mbps, 36 Mbps, 48 Mbps, and 54 Mbps is optional.
- Unless otherwise specified, the configuration shall be performed in AC configuration mode on the AC device.

Verification

- You can run the **show running** command to display the configuration information of the rate set.

Related Commands

Configuring the 11a Rate Set

Command	**802.11a network rate** { **6** | **9** | **12** | **18** | **24** | **36** | **48** | **54** } { **disable** | **mandatory** | **supported** }
Parameter Description	**6**: The rate is 6 Mbps. **9**: The rate is 9 Mbps. **12**: The rate is 12 Mbps. **18**: The rate is 18 Mbps. **24**: The rate is 24 Mbps. **36**: The rate is 36 Mbps. **48**: The rate is 48 Mbps. **54**: The rate is 54 Mbps. **disable**: Disables the rate. **mandatory**: Specifies the mandatory rate. **supported**: Specifies the supported rate.
Command Mode	AC configuration mode
Defaults	N/A
Usage Guide	N/A

Configuring the 11b Rate Set

Command	**802.11b network rate** { **1** | **2** | **5** | **11** } { **disable** | **mandatory** | **supported** }
Parameter	**1**: The rate is 1 Mbps.

Description	**2**: The rate is 2 Mbps. **5**: The rate is 5.5 Mbps. **11**: The rate is 11 Mbps. **disable**: Disables the rate. **mandatory**: Specifies the mandatory rate. **supported**: Specifies the supported rate.
Command Mode	AC configuration mode
Defaults	N/A
Usage Guide	N/A

Configuring the 11g Rate Set

Command	**802.11g network rate** { **1** | **2** | **5** | **6** | **9** | **11** | **12** | **18** | **24** | **36** | **48** | **54** } { **disable** | **mandatory** | **supported** }
Parameter Description	**1**: The rate is 1 Mbps. **2**: The rate is 2 Mbps. **5**: The rate is 5.5 Mbps. **6**: The rate is 6 Mbps. **9**: The rate is 9 Mbps. **11**: The rate is 11 Mbps. **12**: The rate is 12 Mbps. **18**: The rate is 18 Mbps. **24**: The rate is 24 Mbps. **36**: The rate is 36 Mbps. **48**: The rate is 48 Mbps. **54**: The rate is 54 Mbps. **disable**: Disables the rate. **mandatory**: Specifies the mandatory rate. **supported**: Specifies the supported rate.
Command Mode	AC configuration mode
Defaults	N/A
Usage Guide	N/A

2.4.2 Configuring the Beacon Frame Period

Configuration Effect

- Lengthen the Beacon frame period; reduce the frequency of sending Beacon frames; reduce the channel usage for packet management; increase the available channel bandwidth for wireless users.

Notes

- If Beacon frame period is set to too great, users may get disconnected from the WLAN or detect the WLAN frequently.

Configuration Steps

Configuring the Beacon Frame Period

- Optional configuration. By default, the Beacon frame period is 100 milliseconds.
- Unless otherwise specified, the configuration shall be performed in AP configuration mode on the AC device.

Verification

- You can run the **show ap-config running** command to display the configuration information of the Beacon frame period.

Related Commands

Configuring the Beacon Frame Period

Command	**beacon period** *milliseconds* **radio** *radio-id*
Parameter Description	*milliseconds*: Specifies the Beacon frame period, in the range from 20 to 1,000 in the unit of milliseconds. *radio-id*: Specifies the RF interface index, in the range from 1 to 48.
Command Mode	AP configuration mode

Defaults	100 milliseconds
Usage Guide	Configuration for all APs is not supported.

Configuration Examples

Configuring the Beacon Frame Period

Scenario **Figure 2-4**	Configuration Steps	● Set the Beacon frame period of AP1 Radio1 to 300 milliseconds on the AC device.
AC	Ruijie#configure terminal Ruijie(config)#ap-config AP1 Ruijie(config-ap)#beacon period 300 radio 1
Verification	After configuring the Beacon frame period, you can display the configuration information of the Beacon frame period for a check. ● You can run the **show ap-config running** command to display the configuration information of the Beacon frame period.

2.4.3 Configuring Layer 2 Isolation of Wireless Users in a VLAN

Configuration Effect

- Configure this function for the network not requiring layer 2 mutual-access to decrease network attacks and multicast packet bandwidth usage.

Notes

- None.

Configuration Steps

Configuring WLAN-Based User Isolation for an AP

- Optional configuration. By default, WLAN-based user isolation is disabled for the AP.
- Unless otherwise specified, the configuration shall be performed in WIDS configuration mode on the AC device.

Configuring User Isolation for an AP

- Optional configuration. By default, user isolation is disabled for the AP.
- Unless otherwise specified, the configuration shall be performed in WIDS configuration mode on the AC device.

Configuring WLAN-Based User Isolation for an AC

- Optional configuration. By default, WLAN-based user isolation is disabled for the AC.
- Unless otherwise specified, the configuration shall be performed in WIDS configuration mode on the AC device.

Configuring User Isolation for an AC

- Optional configuration. By default, user isolation is disabled for the AC.
- Unless otherwise specified, the configuration shall be performed in WIDS configuration mode on the AC device.

Verification

- You can run the **show running** command to display the configuration information of layer 2 isolation of wireless users in a VLAN.

Related Commands

Configuring WLAN-Based User Isolation for an AP

2.4.4 Configuring Rate Limit for Wireless Users

Configuration Effect

- To make limited network resources serve more users, ensure that the device supports the traffic rate limit function. When the data traffic accords with the committed rate, data packets are allowed to pass. When the data traffic does not accord with the committed rate, data packets are discarded.

Notes

- When the data traffic does not accord with the committed rate, data packets are discarded.

Configuration Steps

Configuring AP-Based Rate Limit

- Optional configuration. By default, AP-based rate limit is disabled.
- Unless otherwise specified, the configuration shall be performed in AP configuration mode on the AC device.

Configuring Client-Based Rate Limit

- Optional configuration. By default, client-based rate limit is disabled.
- Unless otherwise specified, the configuration shall be performed in AC configuration mode on the AC device.

Configuring WLAN-Based Rate Limit

- Optional configuration. By default, WLAN-based rate limit is disabled.
- Unless otherwise specified, the configuration shall be performed in WLAN configuration mode on the AC device.

Verification

- You can run the **show running** command to display the configuration information of the rate limit for wireless users.

Related Commands

Configuring AP-Based Rate Limit

Command	**ap-based { per-user-limit | total-user-limit } { up-streams | down-streams } average-data-rate** *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	**per-user-limit**: Limits the rates of all users on the AP. **total-user-limit**: Limits the rate of the whole AP is limited. **up-streams**: Limits the rate of uplink traffic. **down-streams**: Limits the rate of downlink traffic. *average-data-rate*: Specifies the average rate limit, in the range from 8 to 261120 in the unit of . *burst-data-rate*: Specifies the burst rate limit, in the range from 8 to 261120 in the unit of .
Command Mode	AP configuration mode
Defaults	AP-based rate limit is disabled by default.
Usage Guide	N/A

Configuring Client-Based Rate Limit

Command	**netuser** *mac-address* **{ inbound | outbound } average-data-rate** *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	*mac-address*: Specifies the MAC address of the user. **inbound**: Limits the rate of uplink traffic. **outbound**: Limits the rate of downlink traffic. *average-data-rate*: Specifies the average rate limit, in the range from 8 to 261120 in the unit of .

	burst-data-rate: Specifies the burst rate limit, in the range from 8 to 261120 in the unit of .
Command Mode	AC configuration mode
Defaults	Client-based rate limit is disabled by default.
Usage Guide	N/A

Configuring WLAN-Based Rate Limit

Command	**wlan-based { per-user-limit | total-user-limit | per-ap-limit } { up-streams | down-streams } average-data-rate** *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	**per-user-limit**: Limits the rates of all users in the WLAN. **total-user-limit**: Limits the rate of the whole WLAN. **per-ap-limit**: Limits the rate of the whole WLAN for each AP separately. **up-streams**: Limits the rate of uplink traffic. **down-streams**: Limits the rate of downlink traffic. *average-data-rate*: Specifies the average rate limit, in the range from 8 to 261120 in the unit of . *burst-data-rate*: Specifies the burst rate limit, in the range from 8 to 261120 in the unit of .
Command Mode	WLAN configuration mode
Defaults	WLAN-based rate limit is disabled by default.
Usage Guide	N/A

Configuration Examples

Configuring Rate Limit for Wireless Users

Scenario Figure 2-6	Configuration Steps	● Limit the maximum uplink average rate and maximum uplink burst rate of each user on AP1 to 256*8 Kbps and 1024*8 Kbps respectively on the AC device. ● Limit the maximum uplink average rate and maximum uplink burst rate of wireless user 14cf.920b.bfce on the AC to 256* 8 Kbps and 1024*8 Kbps respectively on the AC device. ● Limit the maximum uplink average rate and maximum uplink burst rate of each user in WLAN 12 to 256*8 Kbps and 1024*8 Kbps respectively on the AC device.

2.4.5 Configuring the RTS/CTS Protection Mechanism

Configuration Effect

- When co-channel interference exists, a smaller RTS threshold means a higher anti-interference capability. However, more RTS/CTS packets require higher channel usage for packet control, reducing the available channel bandwidth for wireless users. Users can set the RTS threshold to specify the length of the data frame to be sent. RTS/CTS handshake is not performed when a workstation sends a data frame with a length smaller than the RTS threshold.

Notes

- None.

Configuration Steps

↘ Configuring the RTS Threshold

- Optional configuration. By default, the RTS threshold is 2347 bytes.
- Unless otherwise specified, the configuration shall be performed in AP configuration mode on the AC device.

Verification

- You can run the **show ap-config running** command to display the configuration information of the RTS threshold.

Related Commands

Configuring the RTS Threshold

Command	**rts-threshold** *value* **radio** *radio-id*
Parameter Description	*value*: Specifies the RTS threshold, in the range from 257 to 2,347 in the unit of bytes. *radio-id*: Specifies the RF interface index, in the range from 1 to 48.
Command Mode	AP configuration mode
Defaults	The RTS threshold is 2,347 bytes by default.
Usage Guide	N/A

Configuration Examples

Configuring the RTS Threshold

Scenario Figure 2-7	Configuration Steps	● Set the RTS threshold of AP1 Radio1 to 800 bytes on the AC.
AC	`Ruijie#configure terminal` `Ruijie(config)#ap-config AP1` `Ruijie(config-ap)#rts-threshold 800 radio 1`
Verification	After configuring the RTS threshold, you can display the configuration information of the RTS threshold for a check. ● You can run the **show ap-config running** command to display the configuration information of the RTS threshold.

2.4.6 Configuring EDCA Parameters

Configuration Effect

- During actual configuration, you can choose to configure the EDCA parameters on the client or AP based on application requirements. Configuration of EDCA parameters on the client and AP respectively affects the downlink data traffic and uplink data traffic.

Notes

- None.

Configuration Steps

Configuring the EDCA Parameters on the Client

- Optional configuration. By default, the EDCA parameters on the client are as follows:
- Unless otherwise specified, the configuration shall be performed in AP configuration mode on the AC device.

Configuring the EDCA Parameters on the AP

- Optional configuration. By default, the EDCA parameters on the AP are as follows:
- Unless otherwise specified, the configuration shall be performed in AP configuration mode on the AC device.

Verification

- You can run the **show ap-config running** command to display the configuration information of the EDCA parameters.

Related Commands

Configuring the EDCA Parameters on the Client Side

Command	**wmm edca-client** { **back-ground** | **best-effort** | **video** | **voice** } { **aifsn** [*aifsn-value*] **cwmin** [*cwmin-value*] **cwmax** [*cwmax-value*] **txop** [*txop-value*] | **length** [*queue-length*] } **radio** [*radio-id*]
Parameter Description	**back-ground**: Sets the back-ground queue. **best-effort**: Sets the best-effort queue. **video**: Sets the video queue. **voice**: Sets the voice queue. *aifsn-value*: Sets the aifsn value, in the range from 1 to 15. *cwmin-value*: Sets the cwmin value, in the range from 0 to 15. *cwmax-value*: Sets the cwmax value, in the range from 0 to 15. *txop-value*: Sets the txop value, in the range from 0 to 255 in the unit of 32 microseconds. *queue-length*: Sets the AC queue length, in the range from 1 to 768. The default is 768. *radio-id*: Sets the EDCA parameters on the client, in the range from 1 to 48.
Command Mode	AP configuration mode
Defaults	AC / AIFS / CWmin / CWmax / TXOP back-ground / 7 / 4 / 10 / 0 best-effort / 3 / 4 / 10 / 0 video / 2 / 3 / 4 / 94 voice / 2 / 2 / 3 / 47
Usage Guide	The parameter configuration takes effect only when the wmm service is enabled. The cwmax value must be greater than the cwmin value. Otherwise, a message indicating configuration failure is displayed.

Configuring the EDCA Parameters on the AP Side

Command	**wmm edca-radio** { **back-ground** | **best-effort** | **video** | **voice** } { **aifsn** [*aifsn-value*] **cwmin** [*cwmin-value*] **cwmax** [*cwmax-value*] **txop** [*txop-value*] | **noack** } **radio** [*radio-id*]
Parameter Description	**back-ground**: Sets the back-ground queue. **best-effort**: Sets the best-effort queue. **video**: Sets the video queue. **voice**: Sets the voice queue. *aifsn-value*: Sets the aifsn value, in the range from 1 to 15. *cwmin-value*: Sets the cwmin value, in the range from 0 to 15. *cwmax-value*: Indicates setting of the cwmax value, in the range from 0 to 15. *txop-value*: Sets the txop value, in the range from 0 to 255 in the unit of 32 microseconds. **noack**: Enables the no ack policy. The no ack policy is not enabled by default. *radio-id*: Sets radio of the EDCA parameters on the client, in the range from 1 to 48.
Command	AP configuration mode

Mode

2.4.7 Configuring the Allowed Access Signal Strength

Configuration Effect

- You can control the Beacon frame broadcast coverage of the AP to prevent access of remote wireless users. You can also limit the minimum value of the RSSI for wireless users. When the RSSI of the request frame sent from a wireless user is smaller than this minimum value, the access of this wireless user is prohibited.

Notes

- If the minimum RSSI for wireless user access is set to too great, many wireless users may fail to access the WLAN.
- If the management frame transmit power is set to too great, many remote wireless users may fail to discover the network.

Configuration Steps

↘ Configuring the Minimum RSSI for Wireless User Access

- Optional configuration. By default, the minimum RSSI for wireless user access is 0. That is, all users are allowed to access the WLAN, no matter how large the RSSI is.
- Unless otherwise specified, the configuration shall be performed in AP configuration mode on the AC device.

↘ Configuring the Management Frame Transmit Power

- Optional configuration. By default, the management frame transmit power is 0. That is, the management frame transmit power is not configured by default.
- Unless otherwise specified, the configuration shall be performed in AP configuration mode on the AC.

Verification

- You can run the **show ap-config running** command to display the configuration information of the allowed access signal strength.

Related Commands

Configuring the Minimum RSSI for Wireless User Access

Command	**response-rssi** *rssi* **radio** *radio-id*
Parameter Description	*rssi*: Specifies the minimum RSSI for wireless user access, in the range from 0 to 100 in the unit of dB. *radio-id*: Specifies the ID of the radio to be configured, in the range from 1 to 48.
Command Mode	AP configuration mode
Defaults	The default RSSI is 0.
Usage Guide	N/A

Configuring the Management Frame Transmit Power

Command	**coverage-area-control** *power* **radio** *radio-id*
Parameter Description	*power*: Specifies the management frame transmit power, in the range from 0 to32 in the unit of dBm. *radio-id*: Specifies the ID of the radio to be configured, in the range from 1 to 48.
Command Mode	AP configuration mode
Defaults	The default power is 0.
Usage Guide	N/A

Configuration Examples

Configuring the Allowed Access Signal Strength

Scenario **Figure 2-9**	Verification	● Set the minimum RSSI for wireless user access of AP1 Radio1 to 20 dB on the AC. ● Set the management frame transmit power of AP1 Radio1 to 30 dBm on the AC.

AC	Ruijie#configure terminal Ruijie(config)#ap-config AP1 Ruijie(config-ap)#response-rssi 20 radio 1 Ruijie(config-ap)#coverage-area-control 30
Configuration Steps	After configuring the allowed access signal strength, you can display the configuration information of the allowed access signal strength for a check. ● You can run the **show ap-config running** command to display the configuration information of the allowed access signal strength.

2.4.8 Configuring the Number of Access Users Allowed by the AP

Configuration Effect

- Limit the STA number for the AP to implement load balancing to a certain extent, avoiding uneven distribution of AP access users.

Notes

- None.

Configuration Steps

Configuring AP-Based STA Number Limit

- Optional configuration. By default, the AP-based STA number limit is 32.
- Unless otherwise specified, the configuration shall be performed in AP configuration mode on the AC device.

Verification

- You can run the **show ap-config running** command to display the configuration information of the AP-based STA number limit.

Related Commands

Configuring AP-Based STA Number Limit

Command	**sta-limit** *max-num*
Parameter Description	*max-num*: Specifies the AP-based STA number limit, in the range from 1 to 32.
Command Mode	AP configuration mode
Defaults	The default limit is 32.
Usage Guide	N/A

Configuration Examples

Configuring AP-Based STA Number Limit

Scenario Figure 2-10	Configuration Steps	● Set the number of access users allowed by AP1 to 12 on the AC.
AC	Ruijie#configure terminal Ruijie(config)#ap-config AP1 Ruijie(config-ap)#sta-limit 12

Verification	After configuring the number of access users allowed by the AP, you can display the configuration information of the number of access users allowed by the AP for a check. ● You can run the **show ap-config running** command to display the configuration information of the number of access users allowed by the AP.

2.4.9 Configuring a Pure 11n Network

Configuration Effect

- Configure a pure 11n network to prohibit access of non-11n devices; make all the 11n devices of the network to use pure HT header for transmission; reduce the size of the packet header; increase the available channel bandwidth for the wireless users.

Notes

- Pure 11n network does not allow access of non-11n devices.

Configuration Steps

↘ Configuring Whether to Support 11a or Not

- Optional configuration. By default, access of 11a users at 5 GHz is supported.
- This configuration takes effect only when the radio of the AP operates at 5 GHz.

Configuring Whether to Support 11b or Not

- Optional configuration. By default, access of 11b users at 2.4 GHz is supported.
- This configuration takes effect only when the radio of the AP operates at 2.4 GHz.

Configuring Whether to Support 11g or Not

- Optional configuration. By default, access of 11g users at 2.4 GHz is supported.
- This configuration takes effect only when the radio of the AP operates at 2.4 GHz.

Configuring Whether to Support 11na or Not

- Optional configuration. By default, access of 11n users at 5 GHz is supported.
- This configuration takes effect only when the radio of the AP operates at 5 GHz.

Configuring Whether to Support 11ng or Not

- Optional configuration. By default, access of 11n users at 2.4 GHz is supported.
- This configuration takes effect only when the radio of the AP operates at 2.4 GHz.

Verification

- You can run the **show ap-config running** command to display the configuration information of the pure 11n network.

Related Commands

Configuring Whether to Support 11a or Not

Command	**11asupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of the radio to be configured, in the range from 1 to 48.
Command Mode	AP configuration mode
Defaults	802.11a is supported by default.
Usage Guide	This configuration takes effect only when the radio of the AP operates at 5 GHz. Configuration for all APs is not supported.

Configuring Whether to Support 11b or Not

Command	**11bsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of the radio to be configured, in the range from 1 to 48.

Command Mode	AP configuration mode
Defaults	802.11b is supported by default.
Usage Guide	This configuration takes effect only when the radio of the AP operates at 2.4 GHz. Configuration for all APs is not supported.

Configuring Whether to Support 11g or Not

Command	**11gsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of the radio to be configured, in the range from 1 to 48.
Command Mode	AP configuration mode
Defaults	802.11g is supported by default.
Usage Guide	This configuration takes effect only when the radio of the AP operates at 2.4 GHz. Configuration for all APs is not supported.

Configuring Whether to Support 11na or Not

Command	**11nasupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of the radio to be configured, in the range from 1 to 48.
Command Mode	AP configuration mode
Defaults	802.11n at 5GHz is supported by default.
Usage Guide	This configuration takes effect only when the radio of the AP operates at 5 GHz. Configuration for all APs is not supported.

Configuring Whether to Support 11ng or Not

Command	**11ngsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of the radio to be configured, in the range from 1 to 48.
Command Mode	AP configuration mode
Defaults	802.11n at 2.4GHz is supported by default.
Usage Guide	This configuration takes effect only when the radio of the AP operates at 2.4 GHz. Configuration for all APs is not supported.

Configuration Examples

Configuring a Pure 11n Network

Scenario **Figure 2-11**	 ● AP1 Radio1 operates at 2.4 GHz. ● AP1 Radio2 operates at 5.8 GHz.
Configuration Steps	● Configure AP1 Radio1 as a pure 11n network on the AC device. ● Configure AP1 Radio2 as a pure 11n network on the AC device.
AC	`Ruijie#configure terminal` `Ruijie(config)#ap-config AP1` `Ruijie(config-ap)#no 11bsupport enable radio 1` `Ruijie(config-ap)#no 11gsupport enable radio 1` `Ruijie(config-ap)#11ngsupport enable radio 1` `Ruijie(config-ap)#no 11asupport enable radio 2` `Ruijie(config-ap)#11nasupport enable radio 2`
Verification	After configuring a pure 11n network, you can display the configuration information of the pure 11n network for a check. ● You can run the **show ap-config running** command to display the configuration information of the pure 11n network.
	`Ruijie#show ap-config running AP1` `!` `ap-config AP1` ` ap-based per-user-limit up-streams average-data-rate 256 burst-data-rate 1024` ` no 11asupport enable radio 2` ` no 11bsupport enable radio 1` ` no 11gsupport enable radio 1` ` no 11acsupport enable radio 1` ` no 11acsupport enable radio 2` ` 802.11n mcs support 15 radio 1` ` 802.11n mcs support 15 radio 2` ` rts-threshold 800 radio 1` ` coverage-area-control 30` ` response-rssi 20 radio 1`

2.4.10 Configuring Spectrum Navigation

Configuration Effect

- The spectrum navigation function of the WLAN is enabled, guiding access of the dual-band STA to the 5G frequency band.

Configuration Steps

Enabling the Spectrum Navigation Function of the WLAN

- Mandatory configuration.
- Unless otherwise specified, this configuration shall be performed on the AC or fat AP.

Configuring the Lower Limit of STA Signal Strength Accepted by Spectrum Navigation

- Optional configuration. This configuration is performed when the spectrum navigation coverage needs to be adjusted.
- Unless otherwise specified, this configuration shall be performed on the AC.

Configuring the Number of Times for Which Dual-Band STA Access to 2.4G Band is Denied

- Optional configuration. This configuration is performed when dual-band STA access to 2.4G band needs to be denied. If access of many dual-band STAs lasts for a very long time or fails after the configuration, you need to set a lower value or remove the configuration.
- Unless otherwise specified, this configuration shall be performed on the AC.

Configuring the STA Information Aging Time

- Optional configuration. If no dual-band STA switches to a single-band 2.4G STA in the environment, you can configure a relatively large aging time. Otherwise, you can configure a relatively small aging time. If you cannot determine whether this type of switching occurs in the environment, use the default configuration.
- Unless otherwise specified, this configuration shall be performed on the AC.

Configuring the Detection Period Count of Suppression STA

- Optional configuration. If a single-band 2.4G STA cannot discover the WLAN for a long time, you shall decrease the value.
- Unless otherwise specified, this configuration shall be performed on the AC.

Configuring the Threshold of STA Detection Scanning Period

- Optional configuration. If a single-band 2.4G STA cannot discover the WLAN for a long time, you shall decrease the value. It is recommended to use the default setting if the condition is unclear.
- Unless otherwise specified, this configuration shall be performed on the AC.

Verification

- Run the **show band-select configuration** command to display the spectrum navigation parameter configuration on the device.
- Run the **show running-config** command to display whether the spectrum navigation function is enabled for the WLAN.
- After the device operates for a certain time, run the **show band-select statistics** command to display the running statistics on the device.
- Capture packets to check whether spectrum navigation has controlled the active detection process.

Related Commands

Enabling the Spectrum Navigation Function of the WLAN

Command	**band-select enable**
Parameter Description	N/A
Command Mode	WLAN configuration mode
Defaults	Spectrum navigation is disabled by default.
Usage Guide	N/A

Configuring the Lower Limit of STA Signal Strength Accepted by Spectrum Navigation

Command	**band-select acceptable-rssi** *value*
Parameter Description	*value*: Lower limit of STA RSSI accepted by spectrum navigation, in the range from -100 to -50 in the unit of dBm.
Command Mode	Global configuration mode
Defaults	The lower limit of STA RSSI accepted by spectrum navigation is -80 dBm.
Usage Guide	N/A

Configuring the Number of Times for Which Dual-Band STA Access to 2.4G Band is Denied

Command	**band-select access-denial** *value*
Parameter Description	*value*: Number of times for which dual-band STA access to 2.4G band is denied, in the range from 0 to 10.
Command Mode	Global configuration mode
Defaults	0
Usage Guide	N/A

Configuring the STA Information Aging Time

Command	**band-select age-out** { **dual-band** *value* **| suppression** *value* }
Parameter Description	**dual-band** *value*: Aging time of dual-band STA information, in the range from 20 to 120 in the unit of seconds. **suppression** *value*: Aging time of dual-band STA information, in the range from 10 to 60 in the unit of seconds.
Command Mode	Global configuration mode
Defaults	**dual-band** *value:* 60 seconds **suppression** *value:* 20 seconds
Usage Guide	It is recommended that the aging time of dual-band STA information be set to twice to three times as much as the aging time of suppression STA information.

Configuring the Detection Period Count Value of Suppression STA

Command	**band-select probe-count** *value*
Parameter Description	*value*: Detection period count of suppression STA, in the range from 1 to 10.
Command Mode	Global configuration mode
Defaults	2
Usage Guide	N/A

Configuring the Threshold of STA Detection Scanning Period

Command	**band-select scan-cycle** *value*
Parameter Description	*value*: Threshold of STA detection scanning period, in the range from 1 to 1000 in the unit of milliseconds.

Command Mode	Global configuration mode
Defaults	200
Usage Guide	N/A

Configuration Examples

↘ Configuring WLAN Spectrum Navigation for Fit AP Architecture

Scenario Figure 2-12	 The preceding figure shows a wireless network of typical fit AP architecture. ● AC represents a wireless access controller. ● AP1, AP2… and AP*n* are all dual-band APs. ● The AC and APs are connected by layer 2 switching device and layer 3 routing device. ● To configure spectrum navigation WLAN as WLAN 99 with SSID "wlan-bandselect", map the WLAN to the two RF interfaces to all dual-band APs.
Configuration Steps	● Configure spectrum navigation parameters on the AC (optional). ● Enable the spectrum navigation function of WLAN 99 on the AC.
AC	`AC# configure terminal` `AC(config)# wlan-config 99` `AC(config-wlan)# band-select enable`
Verification	Use a dual-band STA to access WLAN "wlan-bandselect". ● Make the STA access the 5G frequency band. (The navigation may fail, and the STA may access the 2.4G frequency band.) ● Display the running statistics of spectrum navigation on the AC, and verify that the count increases.
AC	`A# show band-select statistics` `Band Select Statistics` `  Number of dual band client.............................. 1` `  Number of dual band client added.......................... 1`

	Number of dual band client expired..... 0 Number of suppressed client..... 0 Number of suppressed client added..... 0 Number of suppressed client expired..... 0

Common Errors

- Spectrum navigation parameters are improperly configured.
- The spectrum navigation function is not enabled.
- One of the two RF interfaces of the dual-band AP is disabled.

2.4.11 Configuring One-Click Network Optimization

Configuration Effect

- Improve the network performance.

Configuration Steps

Configuring Network Optimization Options

- Optional.
- Enable network optimization on the AC unless otherwise specified.
- Run the **wopt choose** command to configure network optimization options. At least one option is selected.
- Network optimization options can be configured via the network optimization function to improve network performance. Users can select network optimization options based on recommended configurations and actual network conditions. The **no** form is not supported to restore the configurations before optimization. Therefore, if the configurations are incorrect, modify the configurations in corresponding mode.

Command	**wopt choose** { **band-select-disable** | **band-select-enable** | **low-rate-disable** | **multicast-speed** | **rrm-disable** | **rrm-enable** | **session-limit** | **speed-limit** }
Parameter Description	**band-select-disable**: Disables the 5 GHz preferred function. If only few STAs supporting 5 GHz exist in the environment, it is recommended that the 5 GHz preferred function be disabled. **band-select-enable**: Enables the 5 GHz preferred function. If a large number of STAs supporting 5 GHz exist in the environment, it is recommended that the 5 GHz preferred function be enabled. **low-rate-disable**: Forbids low-rate packets. Packets with a rate lower than 11 Mbps are forbidden. **multicast-speed**: Restores the default multicast rate (24 Mbps). **rrm-disable**: Disables the RRM function. If no intra-frequency or inter-frequency interference exists in the environment, it is recommended that the RRM function be disabled. **rrm-enable**: Enables the RRM function. If intra-frequency or inter-frequency interference exists in the environment, it is recommended that the RRM function be enabled to perform channel or power adjustment. **session-limit**: Restores the default number of sessions. The number of sessions affects authentication page pushing by iPortal. It is recommended that the default number of sessions be used. The default number of sessions is 255 for each STA and 1000 for each port. **speed-limit**: Limits the rate. (Rate limiting is performed for all STAs by WLAN. The average uplink and

	downlink rate is 256 kbit/s and the abrupt rate is 300 kbit/s.)
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	Select network optimization options based on environment requirements. Restoring to the configurations before network optimization is not supported. Therefore, exercise caution when selecting network optimization options. If incorrect configurations are optimized, modify the configurations in corresponding configuration mode manually.

Configuring One-Click Network Optimization

- Optional.
- Enable network optimization on the AC unless otherwise specified.
- Run the **wopt enable** command to configure one-click network optimization.
- One-click network optimization can be configured via the network optimization function to improve network performance. The **no** form is not supported to restore the configurations before optimization. Therefore, if the configurations are incorrect, modify the configurations in corresponding mode.

Command	**wopt enable**
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	One-click network optimization can be configured if it is required to forbid low-rate packets, restore default multicast rates for WLANs, restore the default number of sessions, and limit rates for WLANs (average uplink and downlink rate is 256 kbit/s and abrupt rate is 300 kbit/s) in an actual environment. Note: Restoring to the configurations before network optimization is not supported. Therefore, exercise caution when configuring one-click network optimization. If incorrect configurations are optimized, modify the configurations in corresponding configuration mode manually.

Verification

- Run the **show wopt** command to display network optimization information.

Configuration Example

Configuring Network Optimization Options in a Fit AP Architecture

Scenario **Figure 2-13**	 The preceding figure shows a typical wireless network with the fit AP architecture. ● AC is the wireless network controller. ● AP1, AP2, ….APn are dual-band APs. ● The AC and AP are connected through a layer-2 switch and layer-3 router. ● Many STAs supporting 5 GHz exist in the environment. Therefore, it is recommended that the 5 GHz preferred function be enabled, that is, the spectrum navigation function be enabled. ● Low-rate packets are forbidden.
Configuration Steps	● Configure network optimization options on the AC.
AC	AC# configure terminal AC(config)# wopt choose band-select-enable low-rate-disable
Verification	After the user configures network optimization options, display the network optimization information for verification. ● Run the **show wopt** command to display network optimization information.
AC	AC# show wopt Low rate status: 802.11b rate: 1 Mbps: Disable 2 Mbps: Disable 5.5 Mbps: Disable 11 Mbps: Enable 802.11g rate: 1 Mbps: Disable 2 Mbps: Disable 5.5 Mbps: Disable 6 Mbps: Disable 9 Mbps: Disable 11 Mbps: Enable 802.11a rate:

2.4.12 Configuring Intelligent Network Optimization

Configuration Effect

- Perform intelligent network optimization based on network conditions.

Configuration Steps

- Run the **wis enable** command in configuration mode.

Command	**wis enable**
Parameter Description	N/A
Defaults	Intelligent network optimization is not configured by default.
Command Mode	AC global configuration mode
Usage Guide	After this command is run on a running network, intelligent optimization can be performed for the network. In normal cases, this command is used by network management personnel.

Verification

- Run the **show running** command to display the configurations.

Configuration Example

Configuring Intelligent Network Optimization

Scenario **Figure 2-15**	
Configuration Steps	● Enable intelligent network optimization on the AC.
AC	Ruijie#configure terminal Ruijie(config-ac)#wis enable
Verification	After intelligent network optimization is configured, display the configurations for verification. ● Run the **show running** command to display information about intelligent network optimization.
	Ruijie#show running ! wis enable !

2.4.13 Configuring Mcell

Configuration Effect

- Enable dense deployment optimization.

Configuration Steps

- Run the **mcell** command in AP configuration mode.

Command	mcell enable **radio** *radio-id*
Parameter Description	*radio-id*: Indicates the index of an RF port. The value range is 1 to 48.
Defaults	Mcell is disabled by default.
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to display the configurations.

Configuration Example

↘ Configuring Mcell

Scenario **Figure 2-16**	Configuration Steps	● Enable the Mcell function on the AC.
AC	Ruijie#configure terminal Ruijie(config)#ap-config AP1 Ruijie(config-ap)# mcell enable radio 1
Verification	After the Mcell function is configured, display the configurations for verification. ● Run the **show running** command to display information about the Mcell function.
	Ruijie#show ap-config running ap-config AP1 mcell enable radio 1

2.4.14 Configuring Roaming Stickiness

Configuration Effect

- Configure this function to enable roaming stickiness monitoring or navigation.

Notes

- The WIS must be enabled.

Configuration Steps

- Configure roaming stickiness in ap-config all or ap-group configuration mode.

Command	**sticky-steering** { **monitor-only** | **enable** }
Parameter Description	**monitor-only**: Indicates the monitoring mode, that is, only roaming stickiness is monitored. **enable**: Indicates the navigation mode, that is, roaming stickiness navigation is performed if roaming stickiness is detected.
Defaults	By default, roaming stickiness is disabled.
Command Mode	Configure roaming stickiness for all AP groups in ap-config all mode, and configure roaming stickiness for a single AP group in ap-group mode.
Usage Guide	N/A

Verification

- Run **show running** to query the corresponding configuration.

Configuration Example

Configuring Roaming Stickiness

Scenario **Figure 2-17**	Configuration Steps	• Configure roaming stickiness monitoring on the AC. • Configure roaming stickiness navigation on the AC.
AC	`Ruijie#configure terminal` `Ruijie(config)#ap-config all` `Ruijie(config-ap)# sticky-steering monitor-only` `Ruijie(config-ap)# ap-group test1` `Ruijie(config-group)#sticky-steering enable`
Verification	• Run **show running** to query the roaming stickiness configuration information.
	`Ruijie#show running-config` `ap-group test1` ` sticky-steering enable` `!` `ap-group test2` ` sticky-steering monitor-only` `!` `ap-group test3` ` sticky-steering monitor-only` `!`

2.4.15 Configuring Remote Association Information Collection

Configuration Effect

- Enable remote association information collection to enable the WIS client to provide remote association optimization solutions.

Notes

- The WIS must be enabled.

Configuration Steps

- Enable remote association information collection in ap-config all or ap-group configuration mode.

Command	**farpoint-steering enable**
Parameter Description	**enable**: Indicates that remote association information collection is enabled.
Defaults	By default, the remote association information collection function is disabled.
Command Mode	Enable remote association information collection for all AP groups in ap-config all mode and for a single AP group in ap-group mode.
Usage Guide	N/A

Verification

- Run **show running** to query the corresponding configuration.

Configuration Example

Configuring Remote Association Information Collection

Scenario Figure 2-18	Configuration Steps	● Enable remote association information collection on the AC.
AC	`Ruijie#configure terminal` `Ruijie(config)#ap-config all` `Ruijie(config-ap)# farpoint-steering enable` `Ruijie(config-ap)# ap-group test1` `Ruijie(config-group)#no farpoint-steering enable`
Verification	● Run **show running** to query the configuration information about remote association information collection.
	`Ruijie#show running-config` `ap-group test1` `!` `ap-group test2` ` farpoint-steering enable`

	! ap-group test3 farpoint-steering enable !

2.4.16 Configuring Automatic Device Information Upload

Configuration Effect

- Enable automatic upload of AC and AP software and hardware version information to the WIS cloud.

Notes

- If the WIS function is not enabled, AC and AP software and hardware version information will also be automatically uploaded after this function is enabled. The information upload priority is as follows:
- If the WIS client address is configured, the information is uploaded to the WIS client.
- If the WIS client is not configured but the device can access to the WIS public cloud, the information will be uploaded to the WIS public cloud.
- If the WIS client is not configured and the device cannot access to the WIS public cloud, the device information is not uploaded.

Configuration Steps

- Perform this operation in global configuration mode.

Command	**wis devinfo enable**
Parameter Description	**enable**: Indicates that device information is automatically uploaded.
Defaults	By default, automatic device information upload is enabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run **show running** to query the corresponding configuration.

Configuration Example

- N/A

Configuring Automatic Device Information Upload

Scenario **Figure 2-19**	Configuration Steps	● Disable automatic device information upload on the AC.
AC	`Ruijie#configure terminal` `Ruijie(config)# no wis devinfo enable`
Verification	● Run **show running** to query the configuration information about automatic device information upload.
	`Ruijie#show running-config` `no wis devinfo enable!` `!`

2.5 Monitoring

Displaying

Function	Command
Display all configuration information.	**show running**
Display the configuration information of a specified AP.	**show ap-config running** *ap-name*
Display the radio information of all APs.	**show ap-config radio**
Display the configuration information of a specified AP's specified radio.	**show ap-config radio** *radio-id* **config** *ap-name*
Display the detailed status information of an AP's specified radio.	**show ap-config radio** *radio-id* **status** *ap-name*
Display the radio list of an AP.	**show ap-config radio status** *ap-name*
Display the running statistics of band selection.	**show band-select statistics**

Display the network optimization information.	**show wopt**

3 Configuring RF Scheduling

3.1 Overview

The radio frequency (RF) resources mentioned in this document include the RF of an Access Point (AP) as well as a wireless local area network (WLAN) services.

RF scheduling can perform automatic management on the RF resources.

RF scheduling can be used to disable the RF of an AP or a WLAN in the specified time interval, realizing the following functions:

- Reducing network traffic, saving network resources, and preventing waste or abuse of network resources
- Reducing RF interference and saving energy
- Disabling access services in a certain period to reduce potential security risks

RF scheduling can be used in the scenarios where wireless access services are required in specific time cycles.

3.2 Applications

Application	Description
AP RF Scheduling	In a fit AP architecture, enables and disables AP RF as scheduled.
WLAN Scheduling	In a fit AP architecture, enables and disables a WLAN as scheduled.

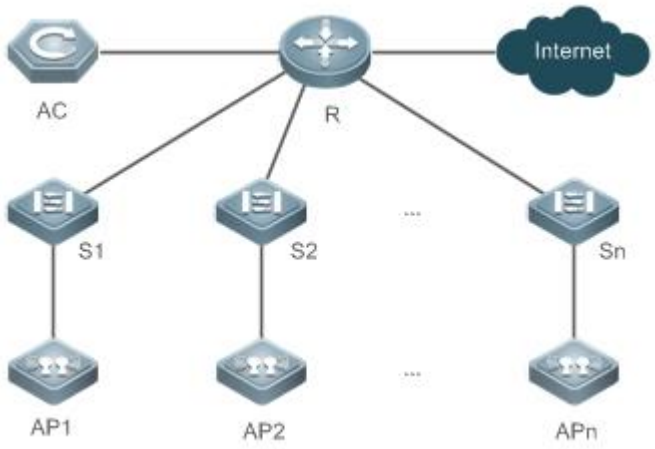
3.2.1 AP RF Scheduling

Scenario

In the scenario where access services need to be provided to wireless stations (STAs) in a specific time period, AP RF scheduling can be used to disable AP RF in the time period when no wireless STAs access the WLAN, thereby preserving network resources and saving energy.

The following figure shows the deployment of a WLAN in a teaching building of a university. The network architecture is a fit AP architecture. AP 1, AP 2, ……, and AP n are the access points located in different places of the building. In the daytime, wireless services need to be provided to students and teachers, but in the nighttime, such services are disabled. By using AP RF scheduling, AP RF of the entire building will be disabled automatically in the nighttime, and enabled again in the daytime. In this way, wireless services are available as scheduled while saving network resources and energy.

Figure 3-1



Deployment

In a fit AP architecture, you can configure AP RF on an AC.

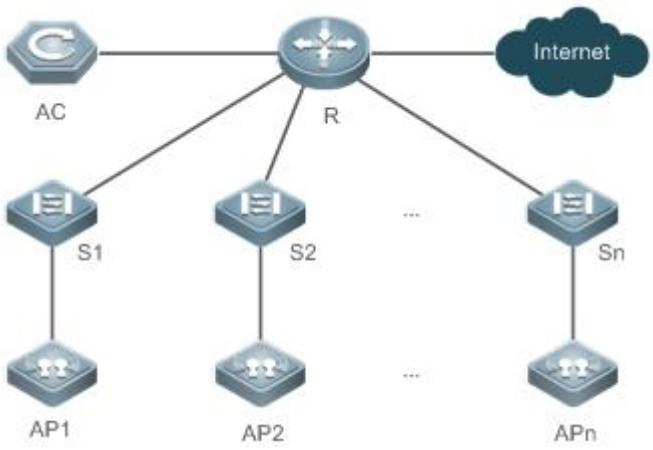
3.2.2 WLAN Scheduling

Scenario

Some WLANs of special use should be enabled only when needed to reduce interference of wireless RF and ensure security.

The following figure shows the deployment of the WLAN a bank business hall. The network architecture is a fit AP architecture. AP 1, AP 2, ……, and AP n are located in different places of the hall to provide free wireless access to customers. Typically, such kind of WLAN does not require a password and is available only during business hours. When WLAN scheduling is applied, the WLAN is automatically enabled during business hours, and disabled after work. In this way, the free customer-use WLAN is disabled, while other WLANs can continue to serve the bank clerks who are still working in the office.

Figure 3-2



Deployment

In a fit AP architecture, configure WLAN scheduling on an AC.

3.3 Features

Basic Concepts

Scheduling Session

A scheduling session indicates a time interval for an RF resource. A simple scheduling session contains only one time interval in a certain day; a complex scheduling session contains many duplicate time intervals in different dates. Currently, one scheduling session supports eight different (or same) time intervals.

For example, you can specify scheduling sessions as follows: 12:00–14:00 and 18:00–8:00 from Monday to Friday; 8:00–12:00 and 17:00–8:00 from Saturday to Sunday.

Overview

Feature	Description
Configuring a Scheduling Session	Specifies a scheduling session.
Scheduling AP RF	Applies a scheduling session to AP RF to enable or disable AP RF periodically.
Scheduling WLAN	Applies a scheduling session to a WLAN to enable or disable the WLAN periodically.

3.3.1 Configuring a Scheduling Session

Specify a scheduling session.

Working Principle

Before using the scheduling function, a scheduling session needs to be created first to specify the time for RF scheduling. Then the scheduling session can be applied to an AP RF interface or WLAN.

Configuring a Scheduling Session

First, you need to create a scheduling session and specify the time and cycle.

For example, in the preceding example, if you want to provide wireless access services only in the daytime to teaching building, you can first create a scheduling session to specify the cycle as every day, and the scheduling interval as a period at night, for example, 21:00 to 6:00. If you want to provide WLAN services to customers of a bank only in the business hours of workdays, you can create a scheduling session to specify the cycle as workdays, and the scheduling time interval as off hours, for example, 18:00 to 9:00; and you can create the other cycle as weekends, and the scheduling interval as all day.

3.3.2 Scheduling AP RF

Enable or disable AP RF periodically.

Working Principle

Before using the scheduling function, a scheduling session needs to be created first to specify the time for RF scheduling. Then you can apply the scheduling session to an AP RF interface.

When the scheduling session starts or ends, the system sends a scheduling message. The processing logic of the scheduling message will enable or disable the RF interface of an AP or the RF interfaces of an AP group where this scheduling session is applied.

Applying a Scheduling Session on an RF Interface

After a scheduling session is created, it must be applied to the corresponding AP RF interface so that the scheduling can take effect.

You can specify an AP RF interface in the following three ways:

- Based on all APs
- Based on an AP group
- Based on a single AP

In the preceding three approaches, you can specify a Radio ID for scheduling. If a Radio ID is not specified, the scheduling will be applied to all radios of the AP.

In the example of the teaching building, the AP RF needs to be specified based on actual conditions.

If all APs in this scenario are in the same group, or distributed in a few groups, the AP group-based configuration is recommended. If all the APs are located in the teaching building, the configuration based on all APs is also recommended. As the last choice, you can still specify the AP RF interface based on a single AP.

Handling of a Scheduling Message

After a scheduling session is created and the cycle and interval are specified, the system will start the timer of the scheduling session, and send a message after entering or exiting from this scheduling session. A scheduling message includes the following information:

- Scheduling Session ID
- Message type: the scheduling state, including entering and exiting from the scheduling session

The handling of a scheduling message covers all APs. The system will determine whether to start scheduling based on the priority of the scheduling Session ID configured for a single AP, AP group, and all APs.

Scheduling priority: The priority of a Session ID is as follows: AP-based Session ID > AP group-based Session ID > all APs-based Session ID. Namely, when a Session ID is configured for an AP, then the AP group-based Session ID and all APs-based Session ID will not take effect on this AP; if no Session ID is configured for an AP, the AP group-based Session ID will take effect; if no AP group-based Session ID is configured for an AP, the all APs-based Session ID will take effect.

If the effective scheduling Session ID of this AP RF is the same as that in the message, the message type will be checked. If in the scheduling state, the radio of this AP will be disabled. Otherwise, the radio will be enabled.

3.3.3 Scheduling WLAN

Enable or disable a WLAN periodically.

Working Principle

Before using the scheduling function, a scheduling session needs to be created first to specify the time for WLAN scheduling. Then the scheduling session can be applied to a WLAN.

When the scheduling session starts or ends, the system sends a scheduling message. In the handling of the scheduling message, the processing logic will locate the WLAN where this scheduling session is applied to, and enable or disable the WLAN.

Applying a Scheduling Session on an RF Interface

After the scheduling session is created, it must be applied to the corresponding WLAN so that the scheduling can take effect.

You need to specify in WLAN configuration mode the scheduling Session ID for the WLAN.

Handling of a Scheduling Message

After a scheduling session is created and the cycle and interval are specified, the system will start the timer of the scheduling session, and send a message after entering or exiting from this scheduling session. A scheduling message includes the following information:

- Scheduling Session ID
- Message type: entering or exiting from the scheduling session

The handling of a scheduling message covers all WLANs. The system will first check the session to which the WLAN is applied. If the scheduling Session ID to which the WLAN is applied is the same as that in the message, the message type will be checked. If in the scheduling state, the WLAN will be disabled. Otherwise, the radio will be enabled.

3.4 Configuration

Configuration	Description and Command	
Configuring AP RF Scheduling	⚠ (Mandatory) It is used to create a scheduling session, specify the time interval, and apply the scheduling session to an AP or AP group.	
	schedule session	Creates a scheduling session.
	schedule session time-range	Specifies the time interval of a scheduling session.
	schedule session	Applies the scheduling session to an AP or an AP group.
Configuring WLAN Scheduling	⚠ (Mandatory) It is used to create a scheduling session and apply it to a WLAN.	
	schedule session	Creates a scheduling session.
	schedule session time-range	Specifies the time interval of a scheduling session.
	schedule session	Applies the scheduling session to a WLAN.

3.4.1 Configuring AP RF Scheduling

Configuration Effect

- Create a scheduling session, specify a scheduling interval, and applies this scheduling session to an AP or an AP group to realize AP RF scheduling.

Configuration Steps

Creating a Scheduling Session

- (Mandatory) In global configuration mode, run the **schedule session** *sid* command to create a scheduling session. *sid* indicates Session ID, which can be set to a value ranging from1 to 64 on an AC, and from 1 to 8 on a fat AP.
- A scheduling session must first be created before use.
- The command must be run on the AC to enable scheduling.

Command	**schedule session** *sid*
Parameter Description	*sid*: Indicates Session ID. It can be set to a value ranging from 1 to 64 on an AC, and from 1 to 8 on a fat AP.
Defaults	By default, no scheduling session is created.
Command Mode	Global configuration mode
Usage Guide	N/A

Specifying the Time Interval for a Scheduling Session

(Mandatory) Run **schedule session** *sid* **time-range** *n* **period** { **everyday** | *day1* [**to** *day2*] } **time** { **all-day** | *hh1:mm1* **to** *hh2:mm2 }* to specify the time interval and cycle of a scheduling session.

- The function must be applied on the AC to enable scheduling.
- **session** *sid:* Indicates Session ID. It can be set to a value ranging from 1 to 64 on an AC, and from 1 to 8 on a fat AP.
- **time-range** *n*: Indicates the number of a time interval, which ranges from 1 to 8.
- **period** *day1* [**to** *day2*]: Indicates the scheduling cycle, where day1 indicates the start date, and day2 indicates the end date, which can be set to { sun | mon | tue | wed | thu | fri | sat }.

  to *day2*: By default, this parameter indicates that the scheduling cycle is one day.
- **period everyday**: Indicates that the session occurs every day, which is the simplified form of **period** *sun* **to** *sat*.
- **time** *hh1:mm1* **to** *hh2:mm2*: Indicates the scheduling time period, and *hh1:mm1* and *hh2:mm2* indicate the start time and end time respectively in the unit of hours (ranging from 0 to 23) and minutes (ranging from 0 to 59).
- **time all-day**: Indicates that the session time range is a whole day, which is the simplified form of **time** *00:00* **to** *23:59*.

Command	**schedule session** *sid* **time-range** *n* **period** { **everyday**	*day1* [**to** *day2*] } **time** { **all-day**	*hh1:mm1* **to** *hh2:mm2* }
Parameter Description	*sid*: Indicates Session ID. It can be set to a value ranging from 1 to 64 on an AC, and from 1 to 8 on a fat AP. *n*: Indicates the number of a time interval, which ranges from 1 to 8. *day1*: Indicates the start date of the scheduling session cycle, which can be set to { sun	mon	tue	wed	thu	fri	sat }. **to** *day2*: *day2* indicates the end date of the scheduling session cycle. By default, this parameter indicates that the scheduling cycle is one day. **everyday**: Indicates that the session occurs every day, which is the simplified form of **period** *sun* **to** *sat*.

	time *hh1:mm1* **to** *hh2:mm2*: Indicates the scheduling time period, and *hh1:mm1* and *hh2:mm2* indicate the start time and end time respectively in the unit of hours (ranging from 0 to 23) and minutes (ranging from 0 to 59). **time all-day**: Indicates that the session time range is a whole day, which is the simplified form of **time** *00:00* **to** *23:59*.
Defaults	No time period or cycle is configured by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Applying a Scheduling Session

- Mandatory.
- The function must be applied on the AC to enable scheduling.
- In AP configuration mode, run the **schedule session** *sid* command to specify the Session ID for APs or a single AP. In AP group configuration mode, run the **schedule session** *sid* command to specify the Session ID for a AP group.
- After a scheduling session is applied, if the message for the scheduling session is displayed, the specified AP RF interface will automatically enter or exit from the scheduling state as specified by the massage type.

Command	**schedule session** *sid* [**radio** *radio-id*]
Parameter Description	*sid*: Indicates Session ID. It can be set to a value ranging from 1 to 64 on an AC. *radio-id*: Indicates ID of the radio on which the session is to be applied or deleted. The value ranges from 1 to the number of radios on the AP. By default, the value is set to the number of radios on the AP.
Defaults	No scheduling session is applied on a single AP, an AP group, or all APs.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Verification

- Run **show running-config** to display configurations on RF scheduling.
- Check whether scheduling is still performed for AP RF after a scheduling session expires.

Configuration Example

Providing WLAN Services to a Teaching Building of a University Only in the Daytime

Scenario **Figure 3-3**	 As shown in the figure, the fit AP architecture is used in this scenario, and only one AC is applied. All the APs in the teaching buildings belong to the same AP group, whose group ID is "class-room".
Configuration Steps	● Create a scheduling session on the AC. ● Specify the scheduling interval as in the nighttime. ● On the AC, apply the scheduling session to AP group "class-room".
AC	`AC# configure terminal` `AC(config)# schedule session 1` `AC(config)# schedule session 1 time-range 1 period sun to sat time 21:00 to 6:00` `AC(config)# ap-group class-room` `AC(config-ap-group)# schedule session 1`
Verification	● On the AC, run the **show running-config** command to display the configuration. ● Display the state of AP RF in the scheduling interval. ● Display the state of AP RF outside the scheduling interval.
AC	`AC# show running-config` `.....` `schedule session 1` `schedule session 1 time-range 1 period Sun to Sat time 21:00 to 06:00` `.....` `ap-group class-room` `.....` `schedule session 1` `.....`

Common Errors

- No scheduling session is created.
- The interval of the scheduling session is not properly configured.
- The scheduling priorities on the AP are in conflict.
- Scheduling is not applied to the target radio.

3.4.2 Configuring WLAN Scheduling

Configuration Effect

- Create a scheduling session, specify a scheduling interval, and apply this scheduling session to a WLAN to realize WLAN scheduling.

Configuration Steps

Creating a Scheduling Session

- (Mandatory) In WLAN configuration mode, run the **schedule session** *sid* command to specify the scheduling Session ID of a WLAN.
- The command must be run on the AC to enable scheduling.
- After a scheduling session is applied, if the message for the scheduling session is displayed, the specified WLAN interface will automatically enter or exit from the scheduling state as specified by the massage type.

Command	**schedule session** *sid*
Parameter Description	**session** *sid*: Indicates Session ID. It can be set to a value ranging from 1 to 64 on an AC, and from 1 to 8 on a fat AP.
Defaults	No scheduling session is applied on a WLAN.
Command Mode	Global configuration mode
Usage Guide	N/A

Specifying the Time Interval for a Scheduling Session

- Mandatory.
- The function must be applied on the AC to enable scheduling.

Command	**schedule session** *sid* **time-range** *n* **period** { **everyday |** *day1* [**to** *day2*] } **time { all-day |** *hh1:mm1* **to** *hh2:mm2* }
Parameter Description	**session** *sid*: Indicates Session ID. It can be set to a value ranging from 1 to 64 on an AC, and from 1 to 8 on a fat AP. **time-range** *n*: Indicates the number of a time interval, which ranges from 1 to 8. **period** *day1*: Indicates the start date of the scheduling session cycle, which can be set to { sun | mon | tue | wed | thu | fri | sat }. **to** *day2*: *day2* indicates the end date of the scheduling session cycle. By default, this parameter indicates that the scheduling cycle is one day. **everyday**: Indicates that the session occurs every day, which is the simplified form of **period** *sun* **to** *sat*. **time** *hh1:mm1* **to** *hh2:mm2*: Indicates the scheduling time period, and *hh1:mm1* and *hh2:mm2* indicate the start time and end time respectively in the unit of hours (ranging from 0 to 23) and minutes (ranging

	from 0 to 59). **time all-day**: Indicates that the session time range is a whole day, which is the simplified form of **time** *00:00* **to** *23:59*.
Defaults	By default, a scheduling session is not configured.
Command Mode	Global configuration mode
Usage Guide	N/A

Applying a Scheduling Session

- Mandatory.
- The function must be applied on the AC to enable scheduling.

Command	**schedule session** *sid*
Parameter Description	**session** *sid*: Indicates Session ID. It can be set to a value ranging from 1 to 64 on an AC, and from 1 to 8 on a fat AP.
Defaults	By default, no scheduling session is configured. No scheduling session is applied on a WLAN or radio.
Command Mode	WLAN configuration mode
Usage Guide	N/A

Verification

- Run **show running-config** to display configurations on RF scheduling.
- Check whether scheduling is still performed for a WLAN after a scheduling session expires.

Configuration Example

Providing WLAN Services to Customers in a Bank Only in the Daytime of Workdays

Scenario **Figure 3-4**	 As shown in the figure, the fit AP architecture is used in this scenario, and only one AC is applied. WLAN 99 is the customer-use WLAN, and the scheduling Session ID is "wlan bank-free". The APs include AP 1, AP 2, ……, and AP n.

Configuration Steps	● Create a scheduling session on the AC. ● On the AC, specify the scheduling intervals as the nighttime of workdays, and the whole weekends. ● On the AC, apply the scheduling session to WLAN 99.
AC	AC# configure terminal AC(config)# schedule session 1 AC(config)# schedule session 1 time-range 1 period mon to fri time 18:00 to 9:00 AC(config)# schedule session 1 time-range 2 period sat to sun time 00:00 to 23:59 AC(config)# wlan-config 99 AC(config-wlan)# schedule session 1
Verification	● On the AC, run the **show running-config** command to display the configuration. ● Display the state of the WLAN in the scheduling interval. ● Display the state of the WLAN outside the scheduling interval.
AC	AC# show running-config …… schedule session 1 schedule session 1 time-range 1 period mon to fri time 18:00 to 9:00 schedule session 1 time-range 2 period sat to sun time 00:00 to 23:59 …… wlan-config 99 wlan-bank-free …… schedule session 1 ……

Common Errors

- No scheduling session is created.
- The interval of the scheduling session is not properly configured.

4 Configuring Band Select

4.1 Overview

Band Select is a technology for optimizing access band distribution for STAs on a WLAN.

The Band Select function leads dual-band STAs to access the higher-capacity 5 GHz band to reduce the pressure on the 2.4 GHz band and improve user experience.

The Band Select function is suitable for the following scenario: dual-band APs are used to provide coverage, and the two RF interfaces of the APs operate at 2.4 GHz and 5 GHz respectively; meanwhile, a WLAN is mapped to the two RF interfaces of the APs and provides access service at the two bands simultaneously.

Protocols and Standards

- IEEE 802.11

4.2 Applications

Application	Description
Band Select for a WLAN Using a Fit AP Architecture	In a fit AP architecture, a WLAN composed of multiple dual-band APs is enabled with the Band Select function.

4.2.1 Band Select for a WLAN Using a Fit AP Architecture

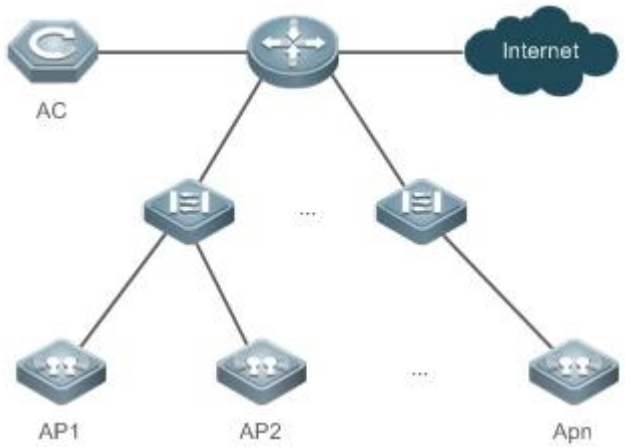
Scenario

In a fit AP architecture, a WLAN composed of multiple dual-band APs is enabled with the Band Select function,

as shown in Figure 4-1,

- One AC is associated with multiple dual-band APs. The AC and APs are connected through layer-2 switch devices and layer-3 routers.
- The WLAN is mapped to the two RF interfaces of all dual-band APs.

Figure 4-1



Remarks	AC is a wireless access controller. AP_1, AP_2 … AP_n are dual-band APs.

Deployment

- Manage parameters of the Band Select function on the AC.
- Apply the Band Select function, identifies STA types and leads STA access on the AC.

4.3 Features

Basic Concepts

IEEE802.11 Communication Band

IEEE802.11 comprises two communication bands:

- 2.4 GHz (2.4 to 2.4835 GHz), where 802.11b/g/n resides
- 5 GHz (5.15 to 5.35 and 5.725 to 5.825 GHz), where 802.11a/n resides

With the popularization of WLANs, there are more and more wireless users. Many users use dual-band wireless clients (STAs) supporting both 2.4 GHz and 5 GHz. However, 802.11b/g is more widely applied than 802.11a. Many dual-band STAs use 2.4 GHz, causing congestion of 2.4 GHz and waste of 5 GHz. Actually, the 5 GHz band has a greater access capacity. The 2.4 GHz band has up to three non-overlapped channels, whereas the 5 GHz band provides more non-overlapped channels.

STA Scanning

There are two modes, namely, passive scanning and active scanning.

- Passive scanning: An STA monitors beacon frames sent by nearby APs on all channels of all supported bands. The beacon frames contain WLAN access information. The STA parses the information to learn about the WLANs that are available nearby.
- Active scanning: The STA broadcasts a Probe Request frame on all channels of all supported bands. After receiving the Probe Request frame, the APs providing WLAN access service sends a Probe Response frame including some WLAN information to the STA.

Generally, the STA summarizes the SSIDs of all discovered WLANs and provides an accessible WLAN list for users.

Dual-band STA

WLAN network interface cards (WNICs) used by STAs to connect to WLANs are classified into a, b, g and n types, which indicate the 802.11 protocol types supported by the WNICs. 802.11a operates at 5 GHz, 802.11b/g at 2.4 GHz, and 802.11n at 5 GHz and 2.4 GHz.

Therefore, if the specification of a WNIC includes both a and b/g, this WNIC supports both the two bands, namely, a dual-band STA. A dual-band STA can access both the 5 GHz band and the 2.4 GHz band.

Dual-band AP

A dual-band AP is able to access two bands. Therefore, a dual-band AP requires at least two RF interfaces, one for 5 GHz and the other for 2.4 GHz.

A WLAN enabled with Band Select must be mapped to the two RF interfaces of the dual-band AP and provides access service at the two bands.

Overview

Feature	Description
Identifying STA Types	The Band Select function identifies whether an STA is a dual-band STA.
Controlling the Active Scanning Process	The Band Select function controls active scanning of the dual-band STA to prevent the STA from discovering WLANs of the 2.4 GHz band.
Rejecting Accessing the 2.4 GHz Band	The Band Select function rejects the dual-band STA from accessing the 2.4 GHz band and improves the chance of accessing the 5 GHz band.

4.3.1 Identifying STA Types

To lead a dual-band STA to access the 5 GHz band, you should first identify whether the STA is a dual-band STA; that is, identify the band supported by the STA.

Working Principle

Active scanning is an approach for an STA to discover WLANs. When using active scanning, the STA sends a Probe Request frame on each supported channel. If the channel information in the Probe Request frame sent by the STA can be obtained, the bands supported by the STA can be identified.

For example, if an AP receives the Probe Request frame on channels 1-13, the AP learns that the STA supports the 2.4 GHz band. If the AP receives the Probe Request frame on channels 149-165, the AP learns that the STA supports the 5 GHz band.

Since a single-band AP can receive the Probe Request frame only at one band, only a dual-band AP can correctly identify the STA type. This is why the Band Select function requires a dual-band AP be used.

STA Classification Standards

A dual-band AP classifies STAs based on the following standards:

- If the AP can receive the Probe Request frame from an STA both at the 2.4 GHz band and the 5 GHz band, this STA is a dual-band STA.

- If the AP can receive the Probe Request frame from this STA only at the 5 GHz band, the AP learns that this STA is a 5 GHz STA.
- If the AP can receive the Probe Request frame from this STA only at the 2.4 GHz band, the AP learns that this AP is a 2.4 GHz STA.

The AP must wait for a period of time to verify that no Probe Request frame is received at the band; therefore, identifying a single-band STA is time-consuming but does not affect the normal use by users. Among the three types of STAs, the first two types are called the dual-band STAs in the Band Select function and the last type is called the inhibition STAs.

It takes a period of waiting time (fixed to 2 seconds) to determine whether a Probe Request frame is sent at the 5 GHz band. Due to different STA drivers, this time is not applicable to all dual-band STAs. Therefore, STA types may not be correctly identified in the beginning. As long as dual-band STAs can send Probe Request frames at the 5 GHz band later, the correct STA types can be identified.

STA Information Saving

The STA information identified by a dual-band AP must be saved to provide the basis for subsequent responding policies.

Since Probe Request frames sent by STAs are broadcast packets, an AP may receive many Probe Request frames generally. It is unnecessary to save all the frames because some distant STAs may not access the AP. Therefore, the Band Select function saves only the information of STAs that may have access. The selection criterion is the Received Signal Strength Indication (RSSI) of STAs. Only those whose RSSI exceeds a threshold can access the AP, and only then does the identified information need to be saved.

STA Information Aging

Users can configure the bands supported by some STAs; therefore, STA type may change during use.

Take an 802.11a/g/n-supported WNIC for example. The WNIC works as a dual-band STA in the beginning. However, a user disables its 802.11a mode or the support for the 5 GHz channels. Then, the WNIC changes to a single-band 2.4 GHz STA.

In this case, an aging mechanism needs to be used for the identified STA information. After a period of time, the previously identified STA information is discarded.

4.3.2 Controlling the Active Scanning Process

After identifying the bands supported by an STA, a dual-band AP can control the active scanning of the STA according to the STA information. The purpose is to prevent a dual-band STA from discovering 2.4 GHz WLANs and thus lead the dual-band STA to access the 5 GHz band.

Working Principle

During active scanning, the STA broadcasts a Probe Request frame. After receiving the Probe Request frame, an AP sends a Probe Response frame immediately to inform the STA of the accessible WLANs on this AP. During active scanning of a dual-band STA, the STA sends a Probe Request frame and waits for a Probe Response frame on the two bands. After the Band Select function is enabled, the AP controls the active scanning and adopts different response approaches according to actual situations.

Active Scanning Before the Band Select Function Identifies STA Types

If the Band Select function is enabled for a WLAN, the WLAN may have different responses to active scanning of an STA. Before STA types are identified:

- The AP does not respond to Probe Request frames from the 2.4 GHz band.
- The AP responds to Probe Request frames from the 5 GHz band.

After receiving a Probe Request frame from the 2.4 GHz band, the AP cannot determine whether the STA supports the 5 GHz band. To prevent the STA from discovering that the WLAN provides access service at the 2.4 GHz band, the AP responds after the identification process ends.

If the AP receives a Probe Request frame from the 5 GHz band, it indicates that the STA supports the 5 GHz band. In this case, the AP sends a Probe Response frame immediately to tell the STA that WLAN provides access service at the 5 GHz band.

↘ Active Scanning After the Band Select Function Identifies STA Types

When the AP receives a Probe Request frame after identifying the STA type, the AP can find the source MAC address in the Probe Request frame stored on the AP.

- If the STA is a dual-band STA, the AP does not respond to a 2.4 GHz Probe Request; if the STA is an inhibition STA, the AP responds negatively
- The AP responds to a 5 GHz Probe Request .

Not responding to a 2.4 GHz Probe Request sent by a dual-band STA can prevent the dual-band STA from discovering that a WLAN provides access service at the 2.4 GHz band. In this way, the dual-band STA only discovers that the WLAN provides access service at the 5 GHz band. The dual-band STA has to select the 5 GHz band for access.

The AP must responds to the 2.4 GHz Probe Request from an inhibition STA. Since an inhibition STA supports only the 2.4 GHz band, the inhibition STA cannot identify a WLAN if the AP does not respond to the 2.4 GHz Probe Request. However, the response to an inhibition STA is negative.

A 5 GHz Probe Request is sent only by a dual-band STA. Therefore, the AP must send a Probe Response immediately to tell the WLAN to provide access service at the 5 GHz band.

↘ Negative Response to an Inhibition STA

The Band Select function always positively responds to 5 GHz Probe Requests, does not respond to 2.4 GHz Probe Requests sent by dual-band STAs, and responds to Probe Requests from inhibition STAs negatively.

Figuratively speaking, a negative response is a discounted response. For example, when receiving multiple Probe Requests consecutively, the AP sends only one Probe Response.

The negativity depends on two parameters: STA scanning cycle threshold and the probe count of the inhibition STA.

The STA scanning cycle refers to the time for scanning all supported channels during the active scanning of an STA. This time depends on the driver of the STA and varies with STAs. The STA scanning cycle is a value configured by users, which is considered the minimum STA scanning cycle. If the scanning cycle of an STA is smaller than this value, two consecutive scanning cycles may be considered to be one by an AP. This parameter is useful when some STAs send multiple Probe Requests within one scanning cycle.

Example: Assume that an STA scans all channels every 150 milliseconds and sends two Probe Request frames consecutively on each channel. If an AP does not specify the minimum scanning cycle of the STA, the AP cannot identify whether the STA sends two frames within the same scanning cycle or sends the two frames in two consecutive scanning cycles. If the AP sets the minimum scanning cycle of the STA to 200 milliseconds, the two frames are considered to be

sent within the same scanning cycle because their interval is shorter than 200 milliseconds. The probe count of the STA on the AP is 1. Since the specified minimum scanning cycle (200 milliseconds) and the actual scanning cycle (150 milliseconds) are different, the counts are also different. Assume that the STA performs scanning for three consecutive cycles, the count on the AP will be 2 because the first two cycles are considered to be one. However, this problem does not cause inconvenience to users.

The probe count of an STA reflects the negativity of the response. This parameter indicates that an AP sends one response after an inhibition STA performs active scanning for multiple cycles. For example, if the default value is 2, the WLAN on the AP sends a Probe Response frame after the STA performs scanning for two consecutive cycles.

4.3.3 Rejecting Accessing the 2.4 GHz Band

⚠ The Band Select function controls only the active scanning of an STA, but cannot prevent the STA from discovering a 2.4 GHz WLAN through passive scanning. Therefore, some dual-band STAs can still discover 2.4 GHz WLANs and attempt to access the WLANs. In this case, the Band Select function may fail.

The Band Select function can reject 2.4 GHz access requests from dual-band STAs to improve the chance for dual-band STAs accessing the 5 GHz band.

⚠ Rejecting a dual-band STA's 2.4 GHz access request helps facilitate the Band Select function; however, the Band Select function cannot be 100% successful.

Working Principle

After an STA discovers a WLAN for a user to access the WLAN, the STA sends an Authentication Request to the AP at first. Then, the AP sends an Authentication Response to permit or reject the STA's authentication request.

The Band Select function processes the Authentication Request. If the Authentication Request is sent by a dual-band STA at the 2.4 GHz band, the function can reject the Authentication Request until the dual-band STA sends an Authentication Request from the 5 GHz band. Thus, the STA is led to access the 5 GHz band.

Generally, when a dual-band STA searches for access, the STA sends one or more Authentication Requests at a band and waits for responses. If the STA does not receive responses or fails in access, the STA sends Authentication Requests at the other band and waits for responses. However, some dual-band STAs send Authentication Requests only at the 2.4 GHz. For high availability, you can use the Band Select function to set the rejecting count for a dual-band STA.

Assume that a dual-band STA sends Authentication Requests for M times before changing the band, and the rejecting count is set to N. If the dual-band STA attempts to access the 5 GHz band at first, the STA can access the 5 GHz band immediately. If the dual-band STA attempts to access the 2.4 GHz band at first, the STA can access the 5 GHz band only if N is equal to or greater than M; otherwise, the STA accesses the 2.4 GHz band. No matter which band a dual-band STA accesses, if the dual-band STA attempts to access the 2.4 GHz band at first, min (smaller one between M and N) Authentication Requests are rejected or ignored. As a result, the STA's access is delayed. The delay time depends on the driver of the STA. For example, if the STA sends Authentication Requests at the interval of 100 milliseconds and four Authentication Requests are ignored, the access of the STA will be delayed for 400 milliseconds.

⚠ When the Band Select function rejects the access request of a dual-band STA while another access control module such as load balance accepts the access request, the STA will still gain access. This is because the Band Select function plays only the "leading" role during STA access and has a low priority. When the Band Select function conflicts with other functions, the other functions shall prevail.

4.4 Configuration

Configuration	Description and Command	
Configuring Band Select	(Mandatory) It is used to enable the Band Select function for a WLAN.	
	band-select enable	Enables the Band Select function.
	(Optional) It is used to set the parameters of the Band Select function.	
	band-select acceptable-rssi	Configures the minimum RSSI for the Band Select function.
	band-select access-denial	Configures the rejecting count for a dual-band STA's 2.4 GHz access requests.
	band-select age-out	Configures the aging time of STA information.
	band-select probe-count	Configures the probe count of an inhibition STA.
	band-select scan-cycle	Configures the scanning cycle threshold of an STA

4.4.1 Configuring Band Select

Configuration Effect

- Enable the Band Select function for a WLAN to lead dual-band STAs to access the 5 GHz band.

Notes

- N/A

Configuration Steps

Enabling the Band Select Function for a WLAN

- Mandatory.
- If there is no special requirement, enable this function on an AC or a fat AP.

Command	band-select enable
Parameter Description	N/A
Defaults	The Band Select function is disabled.
Command Mode	WLAN configuration mode
Usage Guide	N/A

Configuring the Minimum RSSI for the Band Select Function

- (Optional) It is configured when you want to adjust the coverage of the Band Select function.

- If there is no special requirement, enable this function on an AC or a fat AP.
- The higher the value, the smaller the coverage of the Band Select function; the lower the value, the larger the coverage of the Band Select function. However, if the value exceeds a certain limit, the STA signals that gain access may be too weak, causing the connection rate of the entire network to slow down.

Command	**band-select acceptable-rssi** *value*
Parameter Description	*value*: Specifies the minimum SSID for the Band Select function, ranging from -100 to -50 dBm.
Defaults	The default value is -80 dBm
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Rejecting Count for a Dual-Band STA's 2.4 GHz Access Requests

- (Optional) It is configured when it is necessary to reject the 2.4 GHz access request of dual-band STAs. If many STAs fail in access or it takes much time to access, configure this parameter to a smaller value or to 0.
- If there is no special requirement, enable this function on an AC or a fat AP.
- The more the rejecting count is, the more difficult the dual-band STA accesses the 2.4 GHz band, and the later the STA accesses the 2.4 GHz band. On the other hand, the less the rejecting count is, the easier the dual-band STA accesses the 2.4 GHz band, and the sooner the STA accesses the 2.4 GHz band.

Command	**band-select access-denial** *value*
Parameter Description	*value*: Specifies the rejecting count for a dual-band STA's 2.4 GHz access requests, ranging from 0 to 10.
Defaults	The default value is 2
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Aging Time of STA Information

- (Optional) If no dual-band STAs change to single-band 2.4 GHz STAs, configure a longer aging time. Otherwise, configure a shorter aging time. If it is uncertain, use the Defaults.
- If there is no special requirement, enable this function on an AC or a fat AP.
- The longer the STA information aging time, the longer the lifecycle of STA information, and the less sensitive of an AP to STA's band change. The shorter the STA information aging time, the shorter the lifecycle of STA information, and the more sensitive of an AP to STA's band change.

Command	**band-select age-out** { **dual-band** *value* **| suppression** *value* }
Parameter Description	**dual-band** *value*: Specifies the aging time of dual-band STA information, ranging from 20 to 120 seconds. **suppression** *value*: Specifies the aging time of inhibition STA information, ranging from 10 to 60 seconds.
Defaults	The aging time of dual-band STA information is 60 seconds and the aging time of inhibition STA information is 20 seconds.

Command Mode	Global configuration mode
Usage Guide	It is recommended that the aging time of dual-band STA information be set to twice or three times that of inhibition STA information.

Configuring the Probe Count of an Inhibition STA

- (Optional) If a single-band 2.4 GHz STA cannot discover a WLAN for a long time, this parameter should be set to a smaller value.
- If there is no special requirement, enable this function on an AC or a fat AP.
- The greater the probe count of an STA, the stronger inhibition the Band Select function performs on an inhibition STA, and the more difficult the inhibition STA discovers a WLAN. On the other hand, the smaller the probe count of an STA, the weaker inhibition the Band Select function performs on an inhibition STA, and the easier the inhibition STA discovers a WLAN.

Command	**band-select probe-count** *value*
Parameter Description	*value*: Specifies the probe count of an inhibition STA, ranging from 1 to 10.
Defaults	The default value is 2.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Scanning Cycle Threshold of an STA

- (Optional) If a single-band 2.4 GHz STA cannot discover a WLAN for a long time, this parameter should be set to a smaller value. If it is uncertain, use the Defaults.
- If there is no special requirement, enable this function on an AC or a fat AP.
- The greater the scanning cycle threshold of an STA, the more slowly the probe count of the STA increases, and the more difficult the STA discovers a WLAN. On the other hand, the smaller the scanning cycle threshold of the STA, the more quickly the probe count of the STA increases, and the easier the STA discovers a WLAN.

Command	**band-select scan-cycle** *value*
Parameter Description	*value*: Specifies the scanning cycle threshold of an STA, ranging from 1 to 1000 milliseconds.
Defaults	The default value is 200 milliseconds.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show band-select configuration** command to display parameters of the Band Select function.
- Run the **show running-config** command to check whether the Band Select function is enabled.
- After a period of running, run the **show band-select statistics** command to check the statistics on the AC.
- Check whether the Band Select function controls the active scanning process by capturing packets.

Configuration Example

Configuring Band Select for a WLAN Using a Fit AP Architecture

Scenario **Figure 4-2**	 Figure 4-2 shows a typical WLAN using a fit AP architecture. ● AC is a wireless access controller. ● AP_1, AP_2 … AP_n are dual-band APs. ● The AC and APs are connected through layer-2 switch devices and layer-3 routers. ● The WLAN for which the Band Select function needs to be enabled is WLAN 99, whose SSID is wlan-band select. This WLAN is mapped to the two RF interfaces of all dual-band APs.
Configuration Steps	● (Optional) Configure the parameters of the Band Select function on the AC. ● Enable the Band Select Function for WLAN 99 on the AC.
AC	AC# configure terminal AC(config)# wlan-config 99 AC(config-wlan)# band-select enable
Verification	Access WLAN "wlan-band select" by using a dual-band STA. ● The STA accesses the 5 GHz band. (The STA may also access the 2.4 GHz band upon band selection failure.) ● Check the statistics of the Band Select function on the AC. The count should increase.
AC	A# show band-select statistics Band Select Statistics Number of dual band client..... 1 Number of dual band client added..... 1 Number of dual band client expired..... 0 Number of suppressed client..... 0 Number of suppressed client added..... 0 Number of suppressed client expired..... 0

Common Errors

- The parameters are improper.

- The Band Select function is not enabled.
- One of the two RF interfaces of a dual-band AP is disabled.

4.5 Monitoring

Displaying

Description	Command
Displays the configuration of the Band Select function.	**show band-select configuration**
Displays the statistics of the Band Select function.	**show band-select statistics**

5 Configuring CorrectLink

5.1 Overview

CorrectLink provides an intelligent WLAN clients access solution to identify and guide access behaviors of clients, so that clients can access APs with the optimal performance.

At present, correctLink can perform guidance of 5 GHz preferred, remote association, and load balancing on clients.

The purpose of 5 GHz preferred is to guide clients with 5 GHz capabilities to associate with the 5 GHz signals for better experience.

The purpose of remote association is to prevent clients from associating with overlow-RSSI signals.

The purpose of load balancing is to make clients access lower-load APs when guaranteeing that no remote association occurs.

5.2 Applications

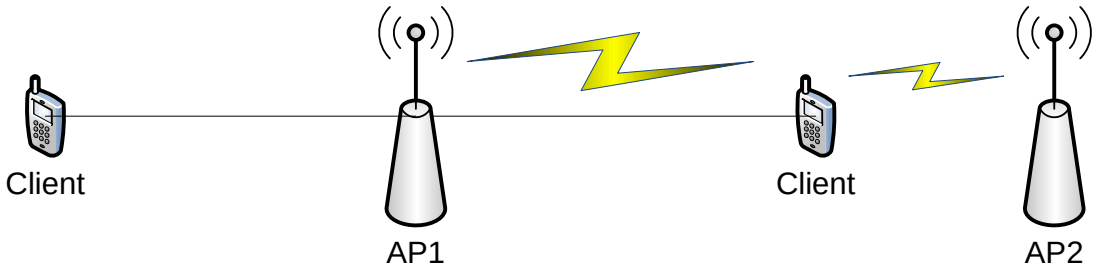
Application	Description
Remote Association	A client is not connected to a near AP, but a far AP. In this case, the client's uplink transmission works at a low rate with poor signals, resulting in poor wireless experience. Remote association can make the client associate with a stronger-signal AP.
5 GHz Preferred	A dual-band client does not select the 5 GHz frequency band, but the 2.4 GHz frequency band. The 2.4 GHz frequency band provides a small number of channels and limited channel resources. It guarantees good client experience in idle time, but degrades client experience in peak-load hours. 5 GHz preferred can guide clients supporting 5 GHz to the 5 GHz frequency band.
Load Balancing	The distribution density of clients is out of control, and client experience is restricted by the access density. In a network environment, even if the network optimization parameters are optimal and clients are connected to the nearest APs and the 5 GHz frequency band, a high access density may degrade the air interface service quality and ultimately affect client experience.

5.2.1 Remote Association

Scenario

As shown in the following figure, a client is not connected to a near AP, but a far AP. In this case, the client's uplink transmission works at a low rate with poor signals, resulting in poor wireless experience. Remote association can make the client associate with a stronger-signal AP.

Figure 5-1



Deployment

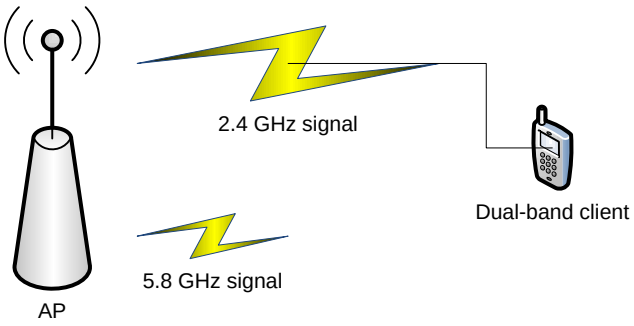
- Enable correctLink to resolve remote association issues.

5.2.2 5 GHz Preferred

Scenario

As shown in the following figure, a dual-band client does not select the 5 GHz frequency band, but the 2.4 GHz frequency band. The 2.4 GHz frequency band provides a small number of channels and limited channel resources. It guarantees good client experience in idle time, but degrades client experience in peak-load hours. 5 GHz preferred can guide clients supporting 5 GHz to the 5 GHz frequency band.

Figure 5-2



Deployment

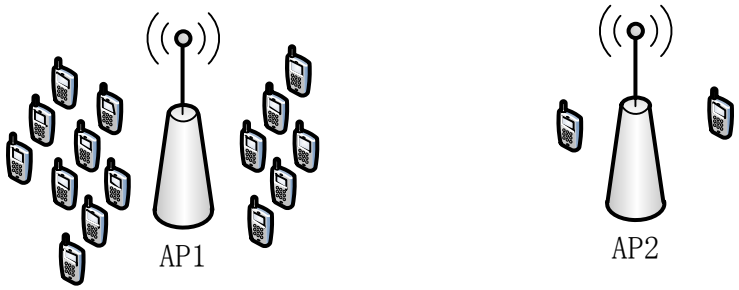
- Enable correctLink to resolve 5 GHz preferred issues.

5.2.3 Load Balancing

Scenario

As shown in the following figure, the distribution density of clients is out of control, and client experience is restricted by the access density. In a network environment, even if the network optimization parameters are optimal and clients are connected to the nearest APs and the 5 GHz frequency band, a high access density may degrade the air interface service quality and ultimately affect client experience.

Figure 5-3



Deployment

- Enable correctLink to resolve load balancing issues.

5.3 Features

Basic Concepts

correctLink

correctLink is a technology that guides clients to achieve the optimal access state, and provides guidance of remote association, 5 GHz preferred, and load balancing.

Overview

Feature	Description
correctLink	Guides clients to achieve the optimal access state.

5.3.1 correctLink

During client access, perform guidance of remote association, 5 GHz preferred, and load balancing on clients, so that the clients achieve the optimal access state.

Working Principle

Judge whether a client accesses the optimal AP based on the information detected during client association and correctLink rules. If the client fails to access the optimal AP, guide access of the client.

correctLink rules:

If the difference between the detected AP RSSI and the highest RSSI is less than 10 dBm (default value), the set of APs is called an APset. If the load of an AP included in the APset is less than that of the currently-accessed AP by a value more than 5 (default value), a Cset exists.

If the currently accessed AP does not belong to the APset, the current access is not optimal, and the client cannot access the AP.

If the currently accessed AP belongs to the APset but the Cset is not null, the current access is not optimal, and the client cannot access the AP.

If the currently accessed AP belongs to the APset and the Cset is null, the current access is optimal, and the client can access the AP.

5.4 Configuration

Configuration	Description and Command	
Configuring correctLink	(Optional) It is used to guide client access.	
	clink enable	Enables correctLink.
	clink rssi-delta-threshold	Configures the remote association RSSI difference threshold of correctLink.
	clink lb-client-threshold	Configures the load balancing judgment threshold of correctLink.
	clink lb-client-delta-threshold	Configures the load balancing difference threshold of correctLink.
	clink bandsel-5g-rssi-threshold	Configures the 5G preferred RSSI threshold of correctLink.
	clink bandsel-5g-client-threshold	Configures the 5 GHz preferred load threshold of correctLink.
	clink max-fails	Configures the rate-limiting attempt threshold of correctLink.

5.4.1 Configuring correctLink

Configuration Effect

- Enable correctLink to identify and guide client based on correctLink rules.

Notes

- If APs in an area belong to different ACs and do not join the virtual AC group, correctLink takes effect only between APs on the same AC, but not across ACs. That is, correctLink does not guarantee the global guiding effect, but only between APs on the same AC.
- If correctLink is configured only on some AP groups, it takes effect only between APs in these AP groups. correctLink does not guarantee the global guiding effect.

Enabling correctLink

- Enable correctLink in global configuration mode or AP group configuration mode.
- After the global configuration takes effect, correctLink applies to all AP groups. However, the **show running** command in the AP groups does not display the configurations.
- When correctLink is configured for a single AP group, the **show running** command in the AP group can display the configurations.
- When the global configuration is enabled, correctLink cannot be configured for a single AP group. To configure correctLink for a single AP group, disable the global configuration first.

Command	**clink enable**
Parameter Description	**enable**: Enables correctLink.

Defaults	correctLink is disabled by default.
Command Mode	Global configuration mode or AP group configuration mode
Usage Guide	N/A

Configuring the Remote Association RSSI Difference Threshold of correctLink

- After the remote association RSSI difference threshold is configured, when the difference between the uplink associated RSSI of the client and the detected highest RSSI is greater than the threshold, it is determined that the client is a remote client and cannot access the AP.

Command	**clink rssi-delta-threshold** *thrd*
Parameter Description	*thrd*: Indicates the RSSI difference threshold.
Defaults	10
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Load Balancing Judgment Threshold of correctLink

- With load balancing enabled, when the load of clients associated with the AP exceeds the load balancing judgment threshold, load balancing judgment is performed.

Command	**clink lb-client-threshold** *thrd*
Parameter Description	*thrd*: Indicates the load balancing judgment threshold.
Defaults	30
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Load Balancing Difference Threshold of correctLink

- When a client detects APs, if the difference between an AP's RSSI and the detected highest RSSI is less than the remote association RSSI threshold, the set of these APs is called an APset.
- After the load balancing difference threshold is configured, it is determined that load imbalance exists and a current client cannot access AP X when all of the following conditions are met:

1. The number of clients associated with AP X is greater than the load balancing enabling threshold.
2. An APset exists and AP Y unassociated with the current client exists in the APset.
3. The number of clients associated with AP Y is less than the number of clients associated with AP X by a value higher than the load balancing difference threshold.

Command	**clink lb-client-delta-threshold** *thrd*
Parameter Description	*thrd*: Indicates the load balancing difference threshold.
Defaults	5
Command	Global configuration mode

Mode	
Usage Guide	N/A

Configuring the 5G Preferred RSSI Threshold of correctLink

- After the 5 GHz preferred RSSI threshold is configured, if a WLAN supports both the 2.4 GHz and 5 GHz frequency bands and the RSSI of 5 GHz signals is greater than the threshold in the WLAN, the client cannot be associated with the WLAN in the 2.4 GHz frequency band.

Command	**clink bandsel-5g-rssi-threshold** *thrd*
Parameter Description	*thrd*: Indicates the 5 GHz preferred RSSI threshold.
Defaults	20
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the 5 GHz Preferred Load Threshold of correctLink

- After the 5 GHz preferred load threshold is configured, if a WLAN supports both the 2.4 GHz and 5 GHz frequency bands and load of 5 GHz signals is less than the threshold in the WLAN, the client cannot be associated with the WLAN in the 2.4 GHz frequency band.

Command	**clink bandsel-5g-client-threshold** *thrd*
Parameter Description	*thrd*: Indicates the 5 GHz preferred load threshold.
Defaults	100
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Rate-limiting Attempt Threshold of correctLink

- After a client is rate-limited for a certain number of times equal to the rate-limiting attempt threshold, stop rate limiting to guarantee access experience of the client.

Command	**clink max-fails** *thrd*
Parameter Description	*thrd*: Indicates the rate-limiting attempt threshold.
Defaults	2
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to display the configurations.

Configuration Example

Enabling correctLink and Configuring the Remote Association RSSI Difference Threshold to 7

Scenario Figure 5-4	Configuration Steps	● Enable correctLink globally on the AC. ● Configure the remote association RSSI difference threshold to 7 on the AC.
AC	`Ruijie#configure terminal` `Ruijie(config)#clink enable` `Ruijie(config)#clink rssi-delta-threshold 7`
Verification	Display the configurations after enabling correctLink for verification. ● Run the **show running** command to display the configurations.
	`Ruijie#show running-config` `!` `clink enable` `clink rssi-delta-threshold 7` `!`

5.5 Monitoring

Displaying

Description	Command
Displays all configuration information.	**show running**
Displays the correctLink result.	**show clink result**

6 Configuring Smartant

6.1 Overview

Smartant means smart antenna, also known as auto-sensing antenna array. It is composed of three parts: antenna array, beam forming network, and beam forming algorithm. By adopting algorithms meeting certain criteria, Smartant adjusts the weighted amplitude and phase of each array signal and thereby adjusts the radiation pattern of the antenna array to enhance required signals and suppress interference signals.

Smartant can solve network interference and signal fading and increase system capacity.

Smartant is usually used in a complex environment where, for example, a lot of obstacles or certain interferences exist.

6.2 Applications

Application	Description
Obstacle environment	Certain obstacles exist in a wireless network environment.

6.2.1 Obstacle Environment

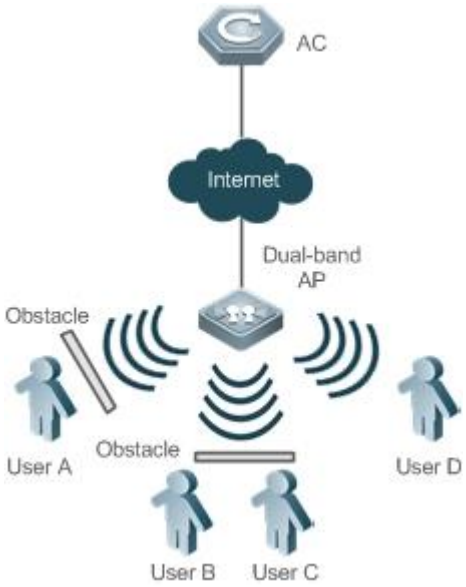
Scenario

Certain obstacles exist in a wireless network environment, for example, load bearing walls and glass windows.

The networking topology is shown as follows:

- Wireless stations (STAs) are evenly distributed around the AP.
- The Smartant function is enabled by default.
- Obstacles exist between certain STAs and the AP.

Figure 6-1 Networking Topology of Smartant



Deployment

- The AP performs downlink wireless packet training and collects data required by Smartant.
- Based on the collected data for Smartant, the AP executes the beam forming algorithm to compute an optimal antenna path for each STA.
- The AP sends data to each STA by the computed optimal path.

6.3 Features

Basic Concepts

Smartant

Based on beamwidth, antennas are divided into omni-directional and directional. Omni-directional antennas usually provide a wide horizontal coverage but a narrow distance, which is contrary to directional antennas. Smartant combines the advantages of both omni-directional and directional antennas. It can cover 360 degree horizontal radiation with a longer distance at each angle.

Wireless Packet Training

Smartant samples STA communication packets for training. When an STA transmits downlink traffic, Smartant changes the direction of packet transmission by setting the transmitting antennas, extracts the rates of packet loss in different antenna directions for evaluation, and finally computes an optimal path for antenna transmission based on the beam forming algorithm.

Overview

Feature	Description
Smartant path selection	Finds an optimal transmission path between the AP and STAs for the best performance.

6.3.1 Smartant Path Selection

With Smartant enabled, the AP can find an optimal transmission path for each STA.

Working Principle

Through downlink packet training and sampling by the AP, an optimal transmission path is found to avoid interferences and obstacles.

6.4 Configuration

Configuration	Description and Command	
Enabling the Smartant function	⚠ (Optional) It is used to configure the Smartant function.	
	smartant enable radio	Configures Smartant.

6.4.1 Configuring Smartant

Configuration Effect

- Configure the Smartant status.

Notes

- If the current device does not support Smartant, the configuration cannot take effect. Currently, Smartant is supported on the following models: AP320-I.

Configuration Steps

↘ Configuring Smartant for a Specified Radio of a Specified AP

- (Optional) Use the **smartant enable radio** *radio-id* command to configure Smartant for a specified in AP configuration mode.
- Except otherwise required, only Smartant-capable APs support Smartant.
- Smartant is configured on per-radio and per-AP basis.

Command	**[no] smartant enable radio** *radio-id*
Parameter Description	*radio-id*: ID of the radio to be configured
Defaults	The Smartant function is enabled by default.
Command Mode	AP configuration mode
Usage Guide	This command is used to enable or disable the Smartant function. For Smartant-incapable devices, the configuration cannot take effect.

Verification

- Run the **show ap-config running** *ap-name* command to verify the configuration.

Configuration Example

↘ Configuring Smartant for a Specified Radio of a Specified AP

Scenario **Figure 6-2**	Configuration Steps	● Configure Smartant for a specified Radio on a specified AP.
	`Ruijie# configure terminal` `Ruijie(config)#ap-config ap320` `Ruijie(config-ap)#smartant enable radio 1`
Verification	After the Smartant function is configured for the specified radio of the specified AP, check the configuration through the following ways. ● Run the **show ap-config running** *ap-name* command to check the configuration. Because Smartant is enabled by default, the **enable** configuration will not be displayed. When the Smartant function is disabled, the information on disabling configuration can be seen.
	`Ruijie(config)#show ap-config running ap320` `!` `ap-config ap320` `...` `...` `no smartant enable radio 2` `...` `...` `!`

6.5 Monitoring

Displaying

Description	Command
Displays AP configuration.	**show ap-config running** *ap-name*

7 Configuring FSS

7.1 Overview

By enabling frequency spectrum scanning (FSS), an AP can operate in the FSS mode and actually act as a wireless frequency spectrum sensor which is responsible for collecting and analyzing non-802.11 wireless signal frequency spectrum and sends the results of frequency spectrum analysis to the frequency spectrum analysis server. After processing, the frequency spectrum analysis server shows the results of frequency spectrum analysis to users in intuitive forms such as graphic, list and alarm.

FSS is used with Ruijie's SNC software to achieve frequency spectrum analysis.

7.2 Applications

Application	Description
Networking with the SNC Software to Achieve Frequency Spectrum Analysis	FSS is networked with Ruijie's SNC software to achieve frequency spectrum analysis.

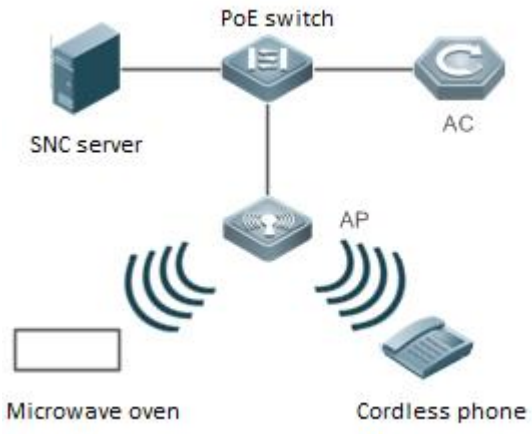
7.2.1 Networking with the SNC Software to Achieve Frequency Spectrum Analysis

Scenario

Ruijie's SNC software achieves frequency spectrum analysis. The SNC software is networked with Ruijie's wireless FIT AP system, as shown in Figure 7-1:

- There are non-802.11 wireless interference devices such as microwave ovens and cordless phones in the RF environment.

Figure 7-1



Remarks	A. The SNC software is installed on the SNC server. B. The AC and AP constitute the wireless FIT AP system.

	C. There are interferences from microwave ovens and cordless phones in the RF environment.

Deployment

- Enable frequency spectrum analysis on the AC.
- Establish a connection between the SNC software and the AC.

7.3 Features

Basic Concepts

Video Bridge Interference

During operation, a video bridge may generate wireless signals that interfere with WLAN transmission. The FSS of an AP can recognize and send the video bridge interferences to the SNC software for analysis.

Microwave Oven Interference

During operation, a microwave oven may generate microwave leakage that interferes with WLAN transmission. The FSS of an AP can recognize and send the microwave interferences to the SNC software for analysis.

Cordless Phone Interference

During operation, a cordless phone may generate wireless signals that interfere with WLAN transmission. The FSS of an AP can recognize and send the cordless phone interferences to the SNC software for analysis.

Bluetooth Interference

During operation, a Bluetooth device may generate wireless signals that interfere with WLAN transmission. The FSS of an AP can recognize and send the Bluetooth device interferences to the SNC software for analysis.

Continuous Wave

During operation, a continuous wave may generate wireless signals that interfere with WLAN transmission. The FSS of an AP can recognize and send the continuous wave interferences to the SNC software for analysis.

Scanning Precision

The scanning precision indicates the serial number of the scanned characteristic waveform which is then determined as a specific interference source. Normally, a higher scanning precision leads to a higher probability of correct determination.

Scanning Duration

When performing frequency spectrum scanning, an AP cannot provide normal wireless services. The system regularly switches between wireless services and frequency spectrum scanning to give consideration to both. A longer scanning duration leads to a higher probability of locating interferences.

Overview

Feature	Description

SNC Connecting to the AC for Frequency Spectrum Analysis	Through the interaction between SNC and AC, non-802.11 interference sources such as microwave ovens, cordless phones, and Bluetooth devices are recognized in a wireless environment.

7.3.1 SNC Connecting to the AC for Frequency Spectrum Analysis

An AP recognizes non-802.11 interference sources such as microwave ovens, cordless phones, and Bluetooth devices in a wireless environment and sends them to the SNC software for sort-out and display through the connection channel established between the AC and the SNC software.

Working Principle

Frequency spectrum analysis is achieved through the interaction and SOCKET connection between SNC and AC. After FSS is enabled, an AP regularly collects non-802.11 interference information in the RF environment and performs Fast Fourier Transform (FFT). Then the AP classifies the information for processing, recognizes and sends specific interference sources to the SNC software via the agreed protocol. After receiving information, the SNC software sorts out and displays the interference information in various ways. For specific operations, refer to Ruijie's user manual for the SNC software.

7.4 Configuration

Configuration	Description and Command	
Enabling FSS	⚠ (Mandatory) It is used to enable FSS.	
	spectral enable	Enables FSS.
Configuring the Interference Recognition Precision for Frequency Spectrum Scanning	⚠ (Optional) It is used to configure the interference recognition precision for frequency spectrum scanning.	
	spectral stability	Configures the interference recognition precision for frequency spectrum scanning.
Configuring the Frequency Spectrum Scanning Duration	⚠ (Optional) It is used to configure the frequency spectrum scanning duration.	
	spectral period	Configures the frequency spectrum scanning duration.

7.4.1 Enabling FSS

Configuration Effect

- Enable FSS.

Notes

- FSS is enabled in the AP configuration mode.

Configuration Steps

Enabling FSS

- (Mandatory) Run the **spectral enable** command to enable or disable FSS in the AP configuration mode.
- Enable FSS for the target AP that is FSS-capable in the AP configuration mode.

Command	**spectral enable**
Parameter Description	N/A
Defaults	FSS is disabled.
Command Mode	AP configuration mode
Usage Guide	-

Verification

Run the **show ap-config running** *ap-name* command to verify that the frequency spectrum scanning precision is configured on the target AP.

Configuration Example

Enabling FSS

Configuration Steps	● Enable FSS for a specified AP.
	Ruijie# configure terminal Ruijie(config)# ap-config AP0001 Ruijie(config-ap)# spectral enable Ruijie(config)# end
Verification	Run the **show ap-config running** *ap-name* command to verify that FSS is enabled on the target AP.
	Ruijie# show ap-config running AP0001 spectral enable

Common Errors

- This command is used in the all AP configuration mode.

7.4.2 Configuring the Interference Recognition Precision for Frequency Spectrum Scanning

Configuration Effect

- Configure the recognition precision of non-802.11 frequency spectrum signals where a larger value leads to a higher precision.

Notes

- FSS must be enabled.

Configuration Steps

Configuring the Interference Recognition Precision for Frequency Spectrum Scanning

- Optional
- The scanning precision is configured in the AP configuration mode, and the default value can be used.

Command	**spectral stability vbr** | **bth** | **bts** | **cph** | **mwo** | **cwa** *num*
Parameter Description	**vbr** *num*: configures the precision of video bridge recognition, ranging 1-5 and 5 by default. **bth** *num*: configures the precision of Bluetooth recognition, ranging 1-4 and 1 by default. **bts** *num*: configures the precision of Bluetooth earphone recognition, ranging 1-2 and 1 by default. **cph** *num*: configures the precision of cordless phone recognition, ranging 3-5 and 5 by default. **mwo** *num*: configures the precision of microwave recognition, ranging 1-5 and 1 by default. **cwa** *num*: configures the precision of continuous wave recognition, ranging 4-10 and 8 by default.
Defaults	See the parameter description.
Command Mode	AP configuration mode
Usage Guide	If there are no special requirements, the default value can be used.

Verification

Run the **show ap-config running** *ap-name* command to verify that the frequency spectrum scanning precision is configured on the target AP.

Configuration Example

Configuring the Frequency Spectrum Scanning Precision

Configuration Steps	• Configure the frequency spectrum scanning precision for video bridges as 2.
	`Ruijie# configure terminal` `Ruijie(config)# ap-config AP0001` `Ruijie(config-ap)# spectral enable` `Ruijie(config-ap)# spectral stability vbr 2` `Ruijie(config)# end`
Verification	Run the **show ap-config running** *ap-name* command to verify the frequency spectrum scanning precision on the target AP.
	`Ruijie# show ap-config running AP0001` `spectral enable` `spectral stability vbr 2`

Common Errors

- FSS is not enabled.
- This command is used in the all AP configuration mode.

7.4.3 Configuring the Frequency Spectrum Scanning Duration

Configuration Effect

- Change the duration required for one cycle of frequency spectrum scanning, 5 ms by default and ranging 1-100 ms.
- A longer scanning duration leads to a higher probability of locating interferences but a bigger influence on normal communication of the AP.

Notes

- FSS must be enabled.

↘ Configuring the Frequency Spectrum Scanning Duration

- Optional
- The scanning duration is configured in the AP configuration mode. If there are no special requirements, the default value can be used.

Command	**spectral period** *num*
Parameter Description	*num*: scanning duration, ranging 1-100 ms, 5 ms by default.
Defaults	5
Command Mode	AP configuration mode
Usage Guide	If there are no special requirements, the default value can be used.

Verification

Run the **show ap-config running** *ap-name* command to verify that the frequency spectrum scanning duration is configured on the target AP.

Configuration Example

↘ Configuring the Frequency Spectrum Scanning Duration as 10 μs

Configuration Steps	● Configure the frequency spectrum scanning duration as 10 μs.
	Ruijie# configure terminal Ruijie(config)# ap-config AP0001 Ruijie(config-ap)# spectral enable Ruijie(config-ap)# spectral period 10 Ruijie(config)# end

Verification	Run the **show ap-config running** *ap-name* command to verify the scanning duration configured on the target AP.
	`Ruijie# show ap-config running AP0001` `spectral enable` `spectral period 10`

Common Errors

- FSS is not enabled.
- This command is used in the all AP configuration mode.

8 Configuring Wireless Location

8.1 Overview

The Wireless Location (WL) function of Ruijie WLAN products uses 802.11 wireless signals to locate terminal stations (STAs). It is supported on all 802.11 a/b/g/n-compliant STAs, such as laptops, Mobile Units (MUs), and special Radio Frequency Identifications (RFIDs, hereinafter mainly referred to as TAGs). By analyzing and summarizing 802.11 wireless signals sent from these STAs, WL achieves STA locations through software on the location server in vivid forms such as maps, tables, or reports.

Ruijie WL also has the following characteristics:

- Support indoor and outdoor deployment.
- Support two algorithms, Received Signal Strength Indication (RSSI) location and Time Difference of Arrival (TDOA) location.
- Support two RFIDs, MUs and TAGs.

8.2 Applications

Application	Description
Centralized Location Deployment	Deploys the location system in fit AP mode.

8.2.1 Centralized Location Deployment

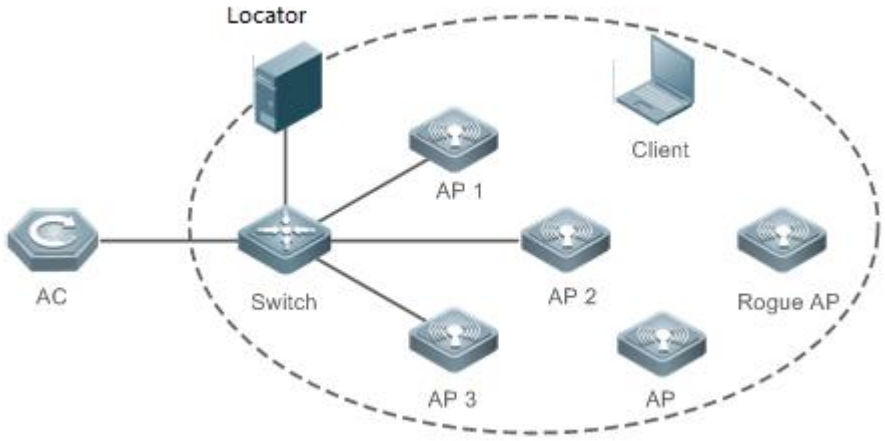
Scenario

Under WLAN in fit AP mode where Access Points (APs) are managed uniformly by the Access Controller (AC), the 802.11 STAs can be located by a Location Server or Locator. The special requirements are:

- Direct access is required between APs and the Locator. Therefore, make sure the ping between them is successful.
- The APs must be WL-capable Ruijie products.
- It is necessary to deploy three APs for accurate location.

The following figure is an example where AP 1, AP 2 and AP 3 can communicate with the Locator. Three APs respectively send received STA information to the Locator which then works out the STA locations.

Figure 8-1



Deployment

- The AC is responsible for WL configuration management and issuing.
- The APs are responsible for collecting STA information and sending the information as specified to the Locator.
- The Locator summarizes all the information sent from all APs, works out the STA locations, and displays the locations in maps or tables based on configurations by the administrator.

8.3 Features

Basic Concepts

A location system contains three parts: the Target or Source, the Receiver, and the Backend Location System.

Target or Source

Ruijie WL supports two types of location targets:

- TAGs, produced by AeroScout, a type of light and portable RFIDs which are usually placed or stuck on the targets to be located.
- MUs, 802.11-complicant wireless STAs regularly transmitting wireless signals.

Receiver

The Receiver can be a Ruijie AP or an AeroScout Tag exciter (used not to collect locations but to excite the TAGs to transmit specified wireless signals).

Backend Location System

The Backend Location System includes a Locator, AeroScout Engine (AE) computing software and all kinds of graphic programs.

Features

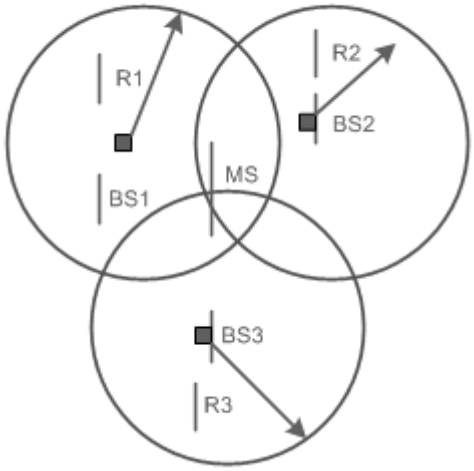
Feature	Description
WL	Enables WL for APs.

8.3.1 WL

Working Principle

Based on the measurement of RSSI from an MU received by a base station (BS) and the channel transmission model, the distance between them can be estimated to be d. In this way, for a BS (i), the MU must be on the circle centered at BS (i) with a radius of d. When three or more BSs are used for distance measurement of the same MU, the location of this MU can be determined. In this method, the main causes for location error are the multipath effect generated during signal transmission and the shadow effect generated during obstacle crossing. More accurate location can be achieved in open space without obstacles. However, in many circumstances, the location accuracy is significantly affected because of uncertainties, such as the multipath effect, attenuation, and scattering, due to various obstacles.

Figure 8-2



8.4 Configuration

Configuration	Description and Command	
Configuring WL Basic Features	(Mandatory) It is used to enable WL.	
	wlocation enable	Enables WL on a specified AP.
	wlocation ae-ip	Configures the IP address of the Locator connected to a specified AP.
	wlocation ae-port	Configures the port ID (PID) of the Locator connected to a specified AP.
	wlocation mu enable	Enables MU location on a specified AP.
	wlocation tag enable	Enables TAG location on a specified AP.
	(Optional) It is used to optimize the WL transmission.	
	wlocation compound enable	Enables the WL aggregation.
	wlocation send-mu-time	Configures the interval for sending MU location information on a specified AP.

Configuration	Description and Command	
	wlocation send-tag-time	Configures the interval for sending TAG location information on a specified AP.
	wlocation mu report enable	Enables WL location report.
	wlocation tag report enable	Enables TAG location report.
	wlocation mu report reduce enable	Simplifies MU location information.
	wlocation ignore beacon enable	Filters Beacon packets sent by APs.

8.4.1 Configuring WL Basic Features

Configuration Effect

- Enable WL to provide basic location services.

Notes

- N/A

Configuration Steps

Enabling WL on an AP

- Mandatory.
- Run the **wlocation enable** command to enable WL on an AP.
- Specify WL targets by running the **wlocation mu enable** and **wlocation tag enable** commands, which are used to enable WL for MUs and TAGs respectively.
- If WL is not enabled or no WL target is specified, WL cannot be used.
- Except as otherwise noted, enable WL for each AP in the deployment where location is required.

Command	**wlocation enable**
Parameter Description	N/A
Defaults	WL is disabled.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring the IP Address and PID for the Locator

- Mandatory.
- The PID is defaulted depending on the configuration of a specific Locator.
- The WL of APs works only with the Locator. Therefore, the IP address and PID of the Locator needs to be configured, guaranteeing its communication with the APs.
- The commands for configuring the IP address and PID are **wlocation ae-ip** *ip-address* and **wlocation ae-port** *port* respectively.

Command	**wlocation ae-ip** *ip-address*
Parameter	*ip-address*: IP address of the Locator

Description	
Defaults	No IP address is configured for the Locator. The AE server's default IP address is 0.0.0.0.
Command Mode	AP configuration mode
Usage Guide	N/A

Command	**wlocation ae-port** *port*
Parameter Description	*port*: PID of the Locator
Defaults	The default PID is 12092.
Command Mode	AP configuration mode
Usage Guide	N/A

Enabling MU or TAG Location

- Mandatory.
- To enable WL on an AP, you need to enable WL for MUs or TAGs. The configuration depends on the scenario and the STA to be located.

Command	**wlocation mu enable**
Parameter Description	N/A
Defaults	MU location is disabled.
Command Mode	AP configuration mode
Usage Guide	Both MU and TAG locations can be enabled at the same time.

Command	**wlocation tag enable**
Parameter Description	N/A
Defaults	TAG location is disabled.
Command Mode	AP configuration mode
Usage Guide	Both MU and TAG locations can be enabled at the same time.

Configuring the Interval for Sending MU or TAG Location Information

- Optional.
- It is used to adjust the interval for sending location information. Except as otherwise noted, the default value is applicable.
- In the scenarios with a lot of STAs to be located, reduce the interval to avoid information losses. (An AP can cache 500 to 700 pieces of location information.)

Command	**wlocation send-mu-time** *interval*

Parameter Description	*interval*: time interval, ranging from 100 to 5,000 ms
Defaults	The default interval is 300 ms.
Command Mode	AP configuration mode
Usage Guide	N/A

Command	**wlocation send-tag-time** *interval*
Parameter Description	*interval*: time interval, ranging from 100 to 5,000 ms
Defaults	The default interval is 300 ms.
Command Mode	AP configuration mode
Usage Guide	N/A

Enabling MU Location Report

- Optional.
- The Locator does not intercommunicate with APs which directly send collected MU location information, for example, through the NAT network. Except as otherwise noted, the default value is applicable.

Command	**wlocation mu report enable**
Parameter Description	N/A
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	With this function enabled, the handshake process of the protocol (referring to the private protocol provided by Aeroscout itself for intercommunication between the Locator and APs) is ignored except through the NAT.

Enabling TAG Location Report

- Optional.
- The Locator does not intercommunicate with APs which directly send collected TAG location information, for example, through the NAT network. Except as otherwise noted, the default value is applicable.

Command	**wlocation tag report enable**
Parameter Description	N/A
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	With this function enabled, the handshake process of the protocol (referring to the private protocol provided by Aeroscout itself for intercommunication between the Locator and APs) is ignored except through the NAT.

Simplifying MU Location Information

- Optional.
- Use this command where there is a requirement for lower traffic bandwidth, and the deployed location system interconnects with the location server developed by Ruijie Networks. Except as otherwise noted, you can apply the configuration on your demand.

Command	wlocation mu report reduce enable
Parameter Description	N/A
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	Enable the function of simplifying MU location information to reduce bandwidth traffic, which applies only when the deployed location server is developed by Ruijie Networks.

Filtering Beacon Packets Sent by APs

- Optional.
- Use this command where there is a requirement for traffic bandwidth reduction. Except as otherwise noted, you can apply the configuration on your demand.

Command	wlocation ignore beacon enable
Parameter Description	N/A
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	Enable the function of filtering Beacon packets sent by APs in Wi-Fi environment to reduce bandwidth traffic.

Verification

In the deployed network, enable STAs to send wireless packets.

- Verify that APs receive wireless location information.
- Verify that the Locator receives location information.

Configuration Example

Enabling WL

Scenario **Figure 8-3**	Configuration Steps	● Enable WL. ● Configure the IP address of the Locator. ● Enable MU location as required. ● Enable TAG location as required. ● Assuming that AP1 in the above figure is named ap1-1, run the following commands to enable ML for this AP.
AP1	`Ruijie# configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.` `Ruijie(config)# ap-config ap1-1` `Ruijie(ap-config)# wlocation enable` `Ruijie(ap-config)# wlocation ae-ip 1.1.1.1` `Ruijie(ap-config)# wlocation mu enable` `Ruijie(ap-config)# wlocation tag enable`
Verification	● Run the **show ap-config** command to display the configurations of each AP and verify ML configuration. ● Assuming that AP1 in the above figure is named ap1-1, run the following commands to verify the ML configuration for this AP.
AP1	`AC5302_7#show ap-config running` `ap-config ap1-1` `wlocation enable` `wlocation ae-ip 1.1.1.1` `wlocation mu enable` `wlocation tag enable`

Common Errors

N/A

9 Configuring RRM 2.0

9.1 Overview

Radio resource management (RRM) is an important function on the AC for managing RF resources of APs.

The RRM analyzes peripheral RF environments and adjusts the RF channel and power of APs based on specific algorithms to prevent signal interference between APs and ensure proper running of the wireless network.

When an AP has strong interference due to a complex RF environment, enabling the RRM function can improve user experience.

9.2 Features

Basic Concepts

STA, AP, and AC

- STA: wireless stations with wireless network interface cards (NICs), for example, laptops and mobile phones
- AP: wireless access point that provides wireless signal access for STAs
- AC: wireless access controller that manages APs and provides wireless network services

RF Environment Information

- STA information: includes the received signal strength indicator (RSSI) and signal-to-noise ratio (SNR) of STAs.
- Neighbor information: includes the RSSI and working channels of neighboring APs.
- Noise: indicates the noise value that affects 802.11 signal receiving, in dBm.
- Interference(%): includes 802.11 signal interference and non-802.11 signal interference. The former indicates signal interference from other APs, and the latter indicates interference from microwave ovens and Bluetooth devices.

Co-channel Interference

When two closely deployed APs work in the same channel, co-channel interference occurs, affecting 802.11 wireless packet receiving.

Overview

Feature	Description
Channel Adjustment	Based on the peripheral RF environment, the AC allocates a proper working channel for an AP to reduce the co-channel interference and improve the wireless access experience of users.
Power Control	When APs are closely deployed and the TX power of an AP is high, the rest APs may be affected. Therefore, the TX power of the AP needs to be lowered to reduce interference.

To perform RRM 2.0 channel adjustment and power control, APs need to support RRM 1.0 or RRM 2.0. Channel adjustment and power control are supported for APs that support RRM 1.0 after they interwork with ACs that support RRM 2.0. However, scanning results reported by APs are limited. When multiple interference signals exist (for example, interference from private APs), the adjustment effect is not optimal.

To display RRM versions supported by online APs, run the **show rrm support** command on the AC.

9.2.1 Channel Adjustment

From a perspective of an AP, channel adjustment prevents the AP from serious interference in the working channel.

From a perspective of the global RF environment, proper channel allocation to each AP ensures the minimum interference between APs and improves the spectrum resource utilization and user experience.

Working Principle

When two closely deployed APs work in the same channel, a wireless signal conflict or interference occurs, affecting wireless user experience.

The ADCA algorithm comprehensively analyzes various environment factors and allocates the optimal working channels for all APs, preventing channel conflicts.

For example, if two APs work in the same channel or two channels with overlapped spectrum resources, the ADCA algorithm will stagger their channels to optimize spectrum resources.

9.2.2 Power Control

Power control is used to lower the TX power of an AP to reduce signal interference between APs.

Working Principle

When an AP is powered on for the first time, it uses the allowed maximum TX power according to national or regional regulations. Higher TX power indicates larger signal coverage. If signal coverage of adjacent APs overlaps and the APs are in the same frequency band, strong co-channel interference exists. The ATPC algorithm determines whether to raise or lower the TX power of an AP based on neighbor information of the AP. When co-channel interference between APs is strong and channels cannot be staggered, the TX power of APs has to be lowered to reduce co-channel interference. If there is no co-channel interference between APs, raise the TX power to expand the signal coverage area.

If channel adjustment and power control are enabled simultaneously, RRM 2.0 preferentially adjusts the channel and then the power. If channels can be staggered, the TX power does not need to be lowered. For this purpose, the ATPC algorithm is executed after the ADCA algorithm.

9.3 Configuration

Configuration	Description and Command	
Configuring Channel Adjustment	(Optional) It is used to configure parameters related to channel adjustment.	
	rrm [**2.4g** | **5g**] **mode enable**	Enables automatic RF adjustment for newly deployed APs.
	rrm [**2.4g | 5g**] **channel dynamic enable**	Enables dynamic channel adjustment.
	rrm [**2.4g | 5g**] **channel bandwidth {current | optimal}**	Selects the channel bandwidth policy during channel adjustment.
	rrm [**2.4g | 5g**] **update channel**	Manually enables channel planning.
	rrm [**2.4g | 5g**] **appoint** *date time*	Reserves a time to adjust the channel and power for all online APs.
Configuring Power Control	(Optional) It is used to configure parameters related to power control.	
	rrm [**2.4g** | **5g**] **mode enable**	Enables automatic RF adjustment for newly deployed APs.
	rrm [**2.4g | 5g**] **update txpower**	Manually enables power planning.
	rrm [**2.4g | 5g**] **appoint** *date time*	Reserves a time to adjust the channel and power for all online APs.

9.3.1 Configuring Channel Adjustment

Configuration Effect

- After channel adjustment is enabled, the AC allocates proper working channels for APs based on their RF environments to improve the wireless network experience.

Configuration Steps

Configuring Channel Adjustment

- Optional. To enable the AC to allocate proper working channels for APs, configure the channel adjustment function.
- Run the **rrm** [**2.4g** | **5g**] **mode enable** command to enable automatic channel adjustment for newly deployed APs.
- Run the **rrm** [**2.4g | 5g**] **channel bandwidth {current | optimal}** command to configure the channel bandwidth policy.
- Run the **rrm** [**2.4g** | **5g**] **channel dynamic enable** command to enable dynamic channel adjustment.
- Run the **rrm** [**2.4g** | **5g**] **update channel** command to manually enable channel planning.
- Run the **rrm** [**2.4g** | **5g**] **appoint** *date time* command to reserve a time to adjust the channel and power for all online APs.

Command	**rrm** [**2.4g** | **5g**] **mode enable**
Parameter Description	**2.4g**: 2.4 GHz network **5g**: 5 GHz network
Defaults	Automatic channel adjustment is disabled for newly deployed APs on the 2.4 GHz and 5 GHz networks by default.

Command Mode	Global configuration mode
Usage Guide	When a newly deployed AP goes online, RF adjustment is performed for the AP. Original configuration is retained for existing APs when they go online. The channel and power of newly deployed APs in the same frequency band are adjusted simultaneously.

Command	**rrm** [**2.4g** | **5g**] **channel bandwidth {current | optimal}**
Parameter Description	**2.4g**: 2.4 GHz network **5g**: 5 GHz network **current**: The current channel bandwidth configuration is selected during channel planning. **optimal**: The optimal channel bandwidth configuration is selected automatically during channel planning.
Defaults	The optimal channel bandwidth policy is configured for the 2.4 GHz and 5 GHz networks by default.
Command Mode	Global configuration mode
Usage Guide	The optimal policy automatically selects the channel bandwidth configuration based on different radio types of APs and channel limitation of radios. The selection rules are as follows: (1) Use HT20 for the 2.4 GHz frequency band. (2) Use HT40 for the 5 GHz frequency band without channel limitations. (3) Use HT40 for radios that are limited to channels 36 to 64. (4) Use HT20 for radios that are limited to channels 149 to 165.

Command	**rrm** [**2.4g** | **5g**] **channel dynamic enable**
Parameter Description	**2.4g**: 2.4 GHz network **5g**: 5 GHz network
Defaults	Dynamic channel adjustment is disabled for the 2.4 GHz and 5 GHz networks by default.
Command Mode	Global configuration mode
Usage Guide	When dynamic channel adjustment is enabled, RRM 2.0 checks channel interference of APs every 5 minutes. If the channel interference exceeds the threshold, RRM 2.0 triggers channel adjustment for the APs. Adjusted channel configuration will overwrite original channel and channel bandwidth configuration (the optimal policy is selected) of APs in ap-config mode. In addition, STAs may be kicked offline due to channel switch during adjustment.

Command	**rrm** [**2.4g** | **5g**] **update channel**
Parameter Description	**2.4g**: 2.4 GHz network **5g**: 5 GHz network
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	After adjustment is completed, automatic RF adjustment is enabled for newly deployed APs in the corresponding frequency band automatically.

Command	**rrm** [**2.4g** | **5g**] **appoint** *date time*
Parameter	**2.4g**: 2.4 GHz network

Description	**5g**: 5 GHz network *date*: reservation date, in the format of yyyy-MM-dd *time*: reservation time, in the format of hh:mm:ss
Defaults	No reservation time is set by default.
Command Mode	Global configuration mode
Usage Guide	The channel and power of online APs will be adjusted simultaneously at the reserved time. After adjustment is completed, automatic RF adjustment is enabled for newly deployed APs in the corresponding frequency band automatically.

Verification

- Run the **show rrm** [**2.4g** | **5g**] **summary** command to display the channel adjustment status.
- Run the **show ap-config summary** command to display the channel adjustment results of APs.

Configuration Example

Configuring Channel Adjustment Parameters

Configuration Steps	Enable automatic channel planning for newly deployed APs.
AC	`AC#configure terminal` `AC(config)#rrm mode enable` `AC(config)#exit`
Verification	Display the channel adjustment status.
AC	`Ruijie#show rrm 2.4g summary` `Radio Resource Management` `  Radio Type..... 2.4G` `  RRM Enable Mode..... Enable` `  Channel Width Strategy..... Optimal` `  Channel Dynamic Enable Mode..... Enable` `  Run Status..... Finish`

9.3.2 Configuring Power Control

Configuration Effect

- After power control is enabled, the AC configures proper TX power for APs based on their RF environments to reduce co-channel interference between the APs.

Notes

- Power control is used to reduce co-channel interference of an AP to other APs. The ATPC algorithm needs to obtain the co-channel interference from other APs to determine whether to control the power. Currently, power control is supported among multiple Ruijie APs.

Configuration Steps

↘ Configuring Power Control

- Optional. To control APs' TX power to prevent co-channel interference between APs, configure the power control function.
- Run the **rrm** [**2.4g** | **5g**] **mode enable** command to enable automatic power adjustment for newly deployed APs.
- Run the **rrm** [**2.4g** | **5g**] **update txpower** command to manually enable power adjustment.
- Run the **rrm** [**2.4g** | **5g**] **appoint** *date time* command to reserve a time to adjust the channel and power for network-wide online APs.

Command	**rrm** [**2.4g**	**5g**] **mode enable**
Parameter Description	**2.4g**: 2.4 GHz network **5g**: 5 GHz network
Defaults	Automatic power adjustment is disabled for newly deployed APs on the 2.4 GHz and 5 GHz networks by default.
Command Mode	Global configuration mode
Usage Guide	When a newly deployed AP goes online, RF adjustment is performed for the AP. Original configuration is retained for existing APs when they go online. The channel and power of newly deployed APs in the same frequency band are adjusted simultaneously.

Command	**rrm** [**2.4g**	**5g**] **update txpower**
Parameter Description	**2.4g**: 2.4 GHz network **5g**: 5 GHz network
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**rrm** [**2.4g**	**5g**] **appoint** *date time*
Parameter Description	**2.4g**: 2.4 GHz network **5g**: 5 GHz network *date*: reservation date, in the format of yyyy-MM-dd *time*: reservation time, in the format of hh:mm:ss
Defaults	No reservation time is set by default.
Command Mode	Global configuration mode
Usage Guide	The channel and power of online APs will be adjusted simultaneously at the reserved time.

Verification

- Run the **show rrm** [**2.4g** | **5g**] **summary** command to display the power adjustment status.
- Run the **show ap-config summary** command to display the channel adjustment results of APs.

Configuration Example

Configuring Power Control Parameters

Configuration Steps	Enable the power adjustment function.
AC	`AC#configure terminal` `AC(config)#rrm mode enable` `AC(config)#exit`
Verification	Display the power control status.
AC	`Ruijie#show rrm 2.4g summary` `Radio Resource Management` `Radio Type..... 2.4G` `RRM Enable Mode..... Enable` `Channel Width Strategy..... Optimal` `Channel Dynamic Enable Mode..... Enable` `Run Status..... Finish`

9.4 Monitoring

Displaying

Description	Command
Displays basic RRM configuration.	**show rrm** [**2.4g** | **5g**] **summary**
Displays RRM versions supported by online APs.	**show rrm support**

10 Configuring 802.11kv

10.1 Overview

The 802.11k protocol revises radio resource measurement (RRM) of the 802.11 protocol, which enables APs and STAs to obtain the RRM data of each other. The 802.11v protocol revised wireless network management (WNM) of the 802.11 protocol. The 802.11k/802.11v protocol enables ACs to manage wireless network resources better and supports the load balancing function. This document describes the application scenarios and configuration methods for channel utilization balancing and STA quantity balancing between radios.

Protocols and Standards

- IEEE 802.11k-2008: Amendment 1: Radio Resource Measurement of Wireless LANs
- IEEE 802.11v-2011: Amendment 8: IEEE 802.11 Wireless Network Management

10.2 Applications

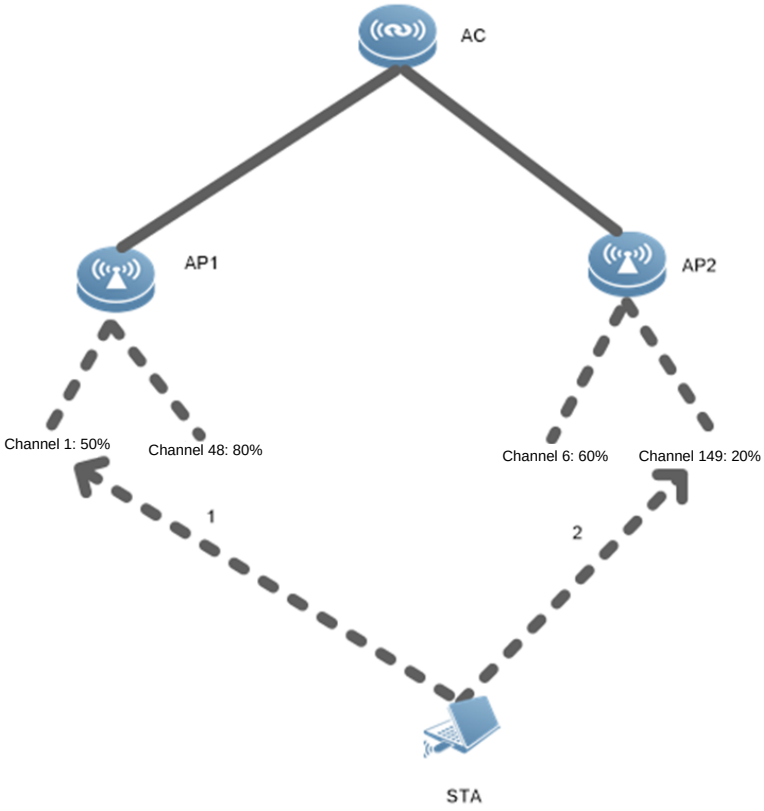
Application	Description
Channel Utilization Balancing	Fit AP networking is adopted, including at least one AC and two APs.
STA Quantity Balancing Between Radios	Fit AP networking is adopted, including at least one AC and two APs.

10.2.1 Channel Utilization Balancing

Scenarios

On a wireless network, especially in high-density STA deployment scenarios, channel utilization is unbalanced due to various reasons. Because STAs cannot perceive the channel utilization, they may select a channel with the highest utilization. Therefore, channel utilization balancing is required to migrate STAs to channels with low utilization within 2s to 10s after STAs go online, to improve user experience.

Figure 10-1



Remarks	AC: wireless access controller AP: wireless access point STA: terminal

Deployment

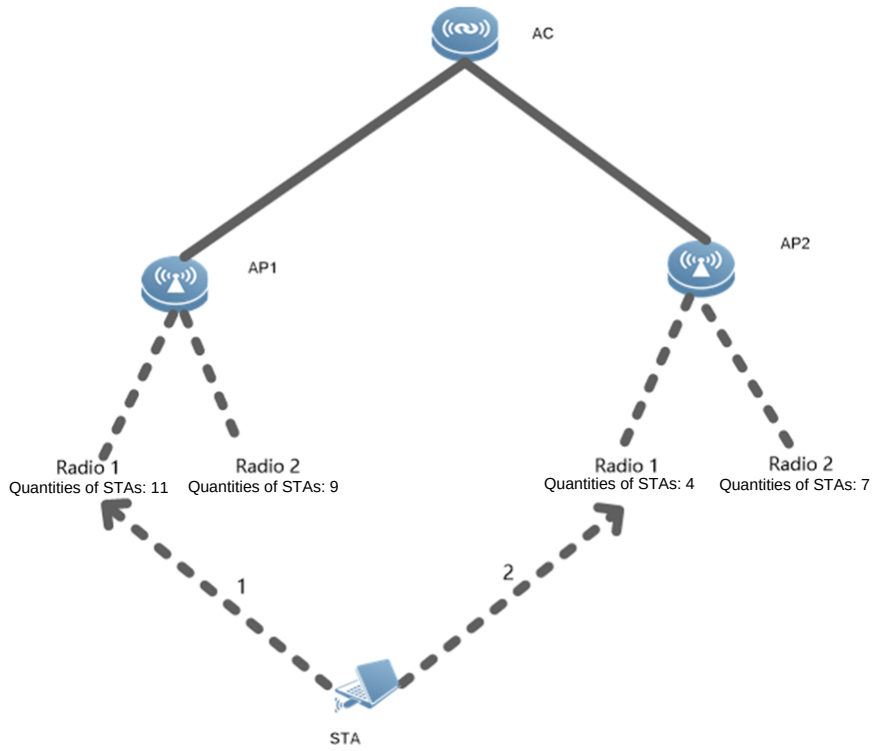
- Set the load balancing mode to channel utilization balancing on the AC.
- Set load balancing parameters on the AC.

10.2.2 STA Quantity Balancing Between Radios

Scenarios

When APs are deployed densely, multiple STAs may connect to the same AP. As a result, the STA quantities on APs are unbalanced.

Figure 10-2



Remarks	AC: wireless access controller AP: wireless access point STA: terminal

Deployment

- Set the load balancing mode to STA quantity balancing between radios on the AC.
- Set parameters of STA quantity balancing between radios on the AC.

10.3 Features

Basic Concepts

Channel Utilization

Channel utilization is an important indicator that affects the STA connection quality. When the traffic is heavy, the quantity of connected STAs is large, or interference is strong, the channel utilization is high. When a STA connects to an SSID that contains multiple BSSIDs, the STA will select a BSSID with the strongest signals. However, the BSSID with the strongest signals may have high channel utilization.

Minimum Load Balancing Value

A minimum value is required to trigger load balancing.

Load Balancing Gain Value

Load balancing is used to obtain better connection quality. If the connection quality and other indicators are not changed or changed slightly after load balancing is enabled, load balancing makes no sense. Therefore, a gain value, namely, a difference value, needs to be set, to determine an improvement produced after a STA is migrated to a radio or channel.

Overview

Feature	Description
Load Balancing	Improves the STA connection quality and balances AP load.

10.3.1 Load Balancing

Load balancing ensures that STAs are evenly distributed on channels or radios to obtain better connection experience.

Working Principle

When a STA that supports the 802.11k protocol is associated with the AC, the AC can obtain the list of available BSSIDs of the STA in real time. Each BSSID corresponds to one value (dBm). If the STA does not support the 802.11k protocol, the AC obtains the list of available BSSIDs of the STA through the probe frame. Load balancing is performed as follows after being enabled:

If a STA is on a channel with 70% or higher utilization, the STA can be migrated to a BSSID with channel utilization 20% less than the current channel and with highest signal strength that is no less than –63 dBm.

If a STA is on a radio with 10 or more connected STAs, the STA can be migrated to a BSSID with 5 STAs less and with highest signal strength that is no less than –63 dBm.

10.4 Configuration

Configuration	Description and Command	
Enabling 802.11k/802.11v	(Optional) It is used to set the policy template.	
	802.11kv enable	Enables the 802.11k/802.11v protocol.
Configuring the load balancing mode	(Mandatory) It is used to set the load balancing mode.	
	802.11kv load-balance mode channel-utilization	Sets the load balancing mode to channel utilization balancing.
	802.11kv load-balance mode station-number	Sets the load balancing mode to STA quantity balancing between radios.
	802.11kv load-balance mode none	Disables load balancing.

10.4.1 Configuring Channel Utilization Balancing

Configuration Effect

- When a STA that supports the 802.11v protocol is associated with a channel with utilization higher than the preset value, and another channel with lower utilization is available (the difference value is lower than the preset gain value), the STA will be migrated to the available channel.

Notes

Load balancing takes effect only to STAs that support 802.11k and 802.11v.

If most STAs do not support 802.11k, run the **sticky-steering enable** command in the ap-group configuration mode. This command is used to learn probe frames sent before a STA is associated, to determine the STA location. However, the command cannot be used to determine the STA location in real time as in 802.11k and is only supported in VAC scenarios.

Configuration Steps

- Mandatory.
- Run the **802.11kv enable** command in global configuration mode on the AC.

Command	802.11kv enable
Parameter Description	N/A
Defaults	802.11k/802.11v is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Setting the Load Balancing Mode

- Mandatory.
- Run the **802.11kv load-balance mode** command in global configuration mode on the AC.

Command	**802.11kv load-balance mode channel-utilization**
Parameter Description	N/A
Defaults	By default, load balancing is not performed.
Command Mode	Global configuration mode
Usage Guide	Channel utilization balancing is triggered when a STA is associated with a channel with utilization equal to or greater than 70% and there are neighboring channels with utilization 20% less than the associated channel.

Verification

- Run the **show running** command to display information based on the policy template and WLAN association information.

10.4.2 Configuring STA Quantity Balancing Between Radios

Configuration Effect

When a STA is associated with a radio on which the quantity of connected STAs is greater than or equal to the preset limit value and there is a neighboring radio on which the quantity of connected STAs is less than the preset limit value, the STA will be migrated to the neighboring radio.

Notes

Load balancing takes effect only to STAs that support 802.11k and 802.11v.

Configuration Steps

Enabling 802.11k/802.11v

- Mandatory.
- Run the **802.11kv enable** command in global configuration mode on the AC.

Command	802.11kv enable
Parameter Description	N/A
Defaults	802.11k/802.11v is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Setting the Load Balancing Mode

- Mandatory.
- Run the **802.11kv load-balance mode** command in global configuration mode on the AC.

Command	**802.11kv load-balance mode station-number**
Parameter Description	N/A
Defaults	By default, load balancing is not performed.
Command Mode	Global configuration mode
Usage Guide	STA quantity balancing between radios is triggered when a STA is associated with a radio on which the quantity of connected STAs is greater than 10 and there is a neighboring radio on which the quantity of connected STAs is 5 STAs less.

Verification

Run the **show running** command to display information based on the policy template and WLAN association information.

Configuration Example

Configuring Channel Utilization Balancing

Scenario **Figure 10-3**	Configuration Steps	Enable 802.11k/802.11v.
AC	`Ruijie(config)802.11kv enable`
	Set the load balancing mode.
	`Ruijie(config)#802.11kv load-balance mode channel-utilization`
Verification	Run the **show run** command to display configuration information.
AC	`Ruijie#show run | begin 802.11kv` `802.11kv enable` `802.11kv load-balance mode channel-utilization`

↘ **Configuring STA Quantity Balancing Between Radios**

Scenario **Figure 10-4**	Configuration Steps	Enable 802.11k/802.11v.
AC	`Ruijie(config)802.11kv enable`
	Set the load balancing mode.
	`Ruijie(config)# 802.11kv load-balance mode station-number`
Verification	Run the **show run** command to display configuration information.
AC	`Ruijie#show run | begin 802.11kv` `802.11kv enable` `802.11kv load-balance mode station-number`

10.5 Monitoring

Displaying

Description	Command
Displays BSTM records sent by the AC to all STAs.	**show 802.11kv all-bstms**
Displays BSTM records sent by the AC to a specific STA.	**show 802.11kv bstms-per-station**

WLAN Security Configuration

1. Configuring Robust Security Network Architecture
2. Configuring WIDS
3. Configuring CPU Protect Policy
4. Configuring NFPP
5. Configuring WAPI

1 Configuring Robust Security Network Architecture

1.1 Overview

The Robust Security Network Architecture (RSNA) function provides security mechanisms for WLANs.

A WLAN uses open media and public electromagnetic waves as a carrier to transmit data signals. Neither communication party is connected with a cable. If transmission links are not properly protected through encryption, data transmission will be at great risk. <Therefore, security mechanisms are especially important in a WLAN.

To enhance the security, a WLAN should be provided with at least the authentication and encryption mechanisms:

- Authentication mechanism: The authentication mechanism is used to authenticate users and allow only specified users (authorized users) to use network resources.
- Encryption mechanism: The encryption mechanism is used to encrypt data on wireless links to ensure that WLAN data can be received and understood only by expected users.

Protocols and Standards

- IEEE Standard for Information technology – Telecommunications and information exchange between systems – Local and metropolitan area networks – Specific requirements -2007
- WI-FI Protected Access – Enhanced Security Implementation Based On IEEE P802.11i Standard -Aug 2004
- Information technology – Telecommunications and information exchange between systems—Local and metropolitan area networks—Specific requirements – 802.11, 1999 IEEE Standard for Local and metropolitan area networks ”Port-Based Network Access Control” 802.1X™ -2004
- 802.11i IEEE Standard for Information technology –Telecommunications and information exchange between systems –Local and metropolitan area networks – Specific requirements

1.2 Applications

Application	Description
WEP Encryption	In a small WLAN that has a lower requirement for security, static WEP encryption can be used to protect wireless data communication.
PSK Access Authentication	For small and medium-sized enterprise networks or family users, access authentication based on pre-shared keys can be used to enhance the security of WLANs.
802.1X Access Authentication	For a scenario that has a higher requirement for security or unified management, port-based network access control can be used.
802.11r	The fast roaming mode Fast BSS Transition (FT) is defined to reduce network delay caused by roaming.

WPA3 Authentication	WPA3 is a wireless authentication security standard released by Wi-Fi Alliance in 2018. Compared with WPA2, it is greatly improved in security.

1.2.1 WEP Encryption

Scenario

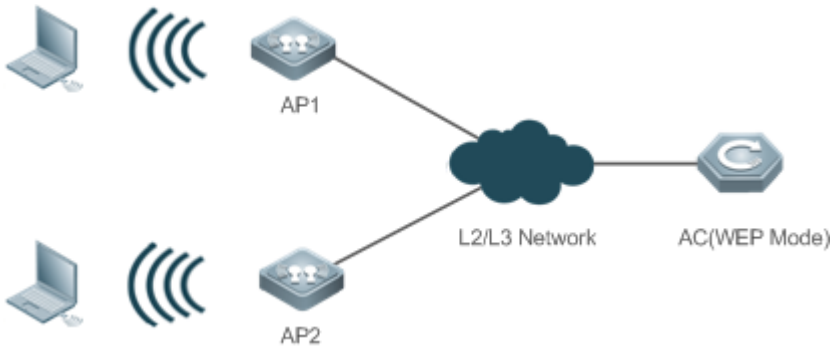
In a small WLAN that has a lower requirement for security, WEP encryption can be used.

WEP encryption can use the open-system or shared-key link authentication mode. Their differences are as follows:

- When open-system link authentication is used, WEP keys can be used only for data encryption. Even if inconsistent keys are configured, users can go online; however, data transmitted after the users go online is discarded by the receiver due to key inconsistency.
- When shared-key link authentication is used, WEP keys are used for link authentication and data encryption. If inconsistent keys are configured, link authentication fails and the client cannot go online.

Figure 1-1 shows the scenario of static WEP encryption.

Figure 1-1



Deployment

- Configure a WLAN on the AC.
- Configure WEP encryption in WLAN security configuration mode.
- Push the WLAN to APs.

1.2.2 PSK Access Authentication

Scenario

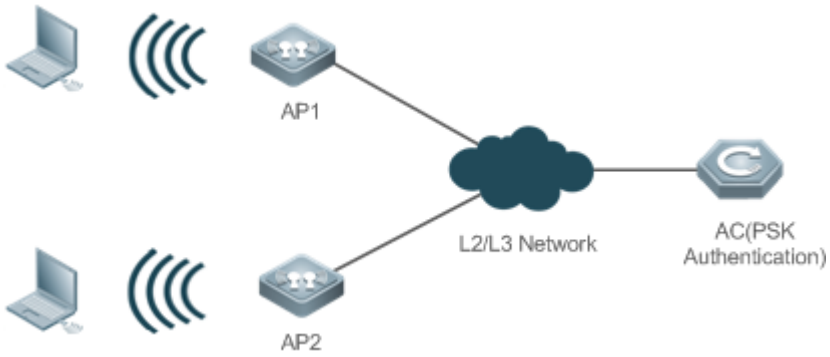
Small and medium-sized enterprise networks or family users can use the WPA or WPA2 standard to enhance WLAN security. The simplest method is to use the pre-shared key authentication (referred to as WPA-PSK and WPA2-PSK respectively). In this case, WPA is similar to WEP, but users can achieve higher security through WPA and 802.11i, including more robust authentication and better encryption algorithms.

In PSK authentication, the same pre-shared key should be configured for an STA and an AP to establish connection and

communication. No additional authentication server is required.

Figure 1-2 shows the scenario of PSK authentication.

Figure 1-2



Deployment

- Configure a WLAN on the AC.
- Configure PSK authentication in WLAN security configuration mode.
- Push the WLAN to APs.
- Use this authentication with WEB authentication to support web-based authentication and charging.

1.2.3 802.1X Access Authentication

Scenario

In a scenario that has a higher requirement for security, 802.1X authentication can be used.

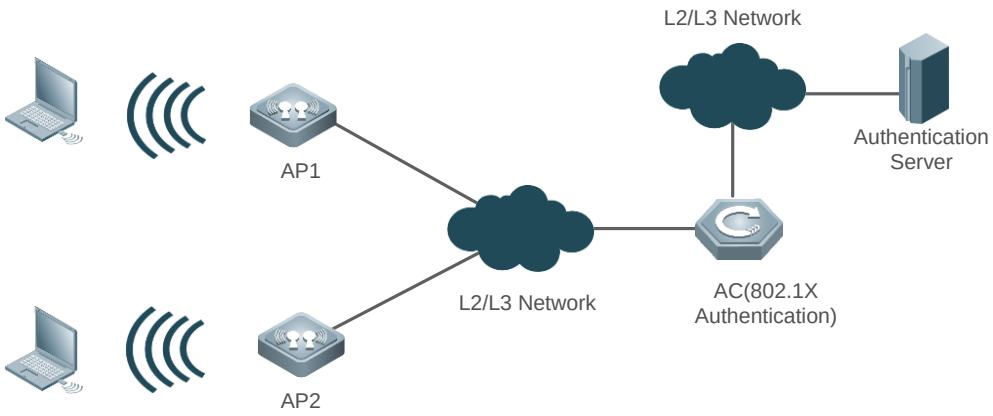
802.1X is a port-based network access control protocol. This authentication mode is used to authenticate and control STAs at the port level. STAs connected to the ports can access a WLAN if they pass the authentication; otherwise, the STAs fail to access the WLAN.

Authentication client software needs to be installed on terminals to perform 802.1X authentication. However, in some cases, some devices cannot be installed with the software, for example, wireless printers. For the sake of network management and security, although these terminals have no 802.1X authentication client software, administrators need to control the access of these terminals. MAC Authentication Bypass (MAB) provides a solution for this application.

After the MAB function is deployed for a WLAN, a wireless device can automatically probe the MAC address of a connected terminal and uses the MAC address to initiate a request to the authentication server.

Figure 1-3 shows the scenario of 802.1X authentication.

Figure 1-3



Deployment

- Configure a WLAN on the AC.
- Configure an authentication server on the AC.
- Configure 802.1X authentication in WLAN security configuration mode.
- Push the WLAN to APs.

1.2.4 802.11r

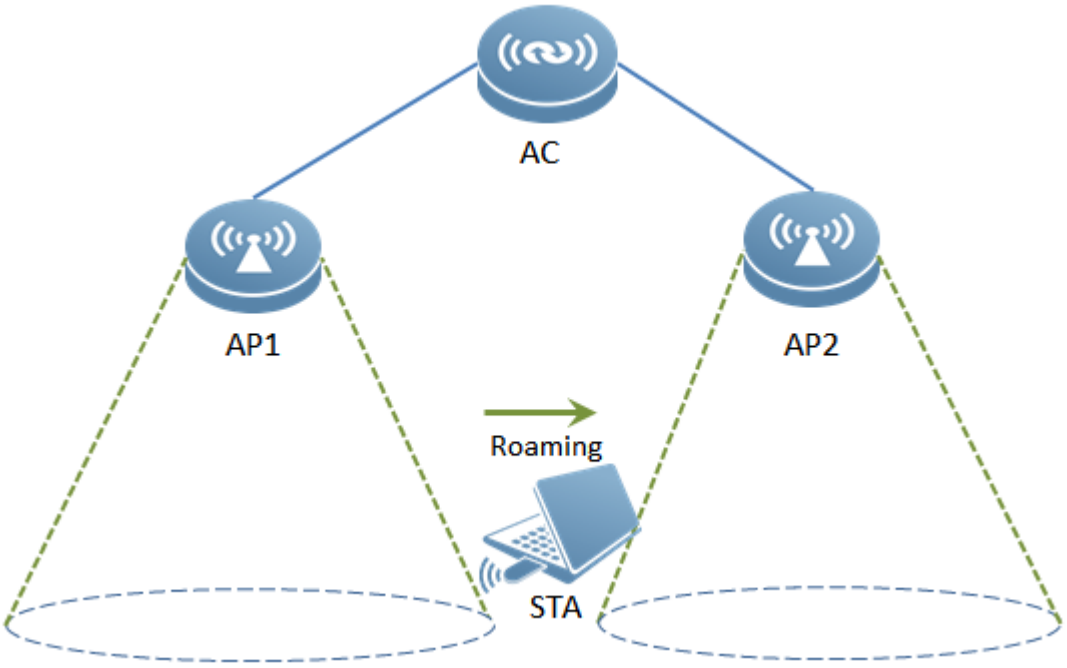
Scenario

For applications that are sensitive to network delay, such as voice over Wi-Fi and video, reducing the roaming authentication time is very important. The 802.11r standard defines the FT roaming mode. In this mode, 802.1x authentication and the 4-way handshake are not required, thereby reducing the roaming handover time.

The FT roaming mode includes the Over the Air and Over the DS methods. Currently, only Over the Air is supported. In this mode, STAs directly connect to a new AP for authentication in roaming scenarios.

The following figure shows the Over the Air application scenario.

Figure 1-4



Deployment

- Configure a WLAN on the AC.
- In WLAN security configuration mode, set authentication mode to RSN, access authentication mode (AKM) to PSK or 802.1x, and encryption mode to AES.
- Deliver the WLAN configuration to APs.
- Simulate a scenario in which an STA roams from AP1 to AP2. If the 802.11r function is enabled, the STA directly connects to AP2 for FT authentication.

1.2.5 WPA3 Authentication

Scenario

Wi-Fi Alliance released the Wi-Fi Protected Access III (WPA3) standard in 2018. This new standard supports three modes: WPA3 Personal, WPA3 Enterprise, and WPA3 Enhanced-Open.

The WPA3 Personal mode is similar to the Pre-shared Key (PSK) mode of WPA2 but the difference is that the Simultaneous Authentication of Equals (SAE) exchange is added in the phase of authentication using management packets. Therefore, the subsequent 4-way handshake no longer uses simple Pairwise Master Keys (PMKs) derived from passwords and it is impossible to intercept 4-way handshake packets to initiate dictionary attacks and crack passwords. Security is greatly enhanced in this mode.

The WPA3 Enterprise mode is similar to the 802.1x authentication of WPA2 but the 4-way handshake uses an updated cipher suite, which raises the overall security from 128-bit encryption to 192-bit encryption. In WPA3 Enterprise mode, security is significantly improved.

In WPA3 Enhanced-Open mode, users do not need to enter authentication information, interactive packets between STAs and APs are encrypted to prevent packet from eavesdropping. It is strong in privacy protection.

Deployment

- Configure a WLAN on an AC.
- Select the WPA3 mode in WLAN security mode.
- Deliver WLAN configuration to APs.

1.3 Features

Basic Concepts

WPA

Wi-Fi Protected Access (WPA) is a wireless security draft defined by the Wi-Fi Alliance. The IEEE802.11i standard is compatible with this draft.

RSN

The IEEE802.11i standard defines the concept of Robust Security Network (RSN): and makes many improvements against various defects of the WEP encryption mechanism. The functions are equal to WPA2 launched by the Wi-Fi Alliance.

TKIP

The Temporal Key Integrity Protocol (TKIP) is an enhancement on WEP security. TKIP provides key mixing, message integrity check and key mechanism re-generation for each packet, thus eliminating hidden risks of WEP.

AES

Advanced Encryption Standard (AES) is a new encryption standard published by the National Institute of Standards and Technology (NIST) of the United States. On October 2, 2000, the Rijndael algorithm designed by Joan Daemen and Vincent Rijmen from Belgium won with its excellent performance and anti-attack capabilities, and became the new-generation encryption standard AES.

CCMP

Counter CBC-MAC Protocol (CCMP) uses AES, which is safer than TKIP.

AKM

Authentication and Key Management (AKM) is an access authentication mode for users to access a WLAN.

SAE

Simultaneous Authentication of Equals (SAE) is a peer authentication interaction, which uses elliptic curve cryptography.

OWE

Opportunistic Wireless Encryption (OWE) does not need users to enter authentication information, and STAs and APs negotiate temporary PMKs.

Overview

Feature	Description
Link Verification	Verify the security of a wireless link before an STA associates with a WLAN.
Access Authentication	Perform authentication for an STA that accesses a WLAN.
Wireless Data Encryption	Implement security protection for communication data of an STA that accesses a WLAN.

1.3.1 Link Verification

Link verification refers to 802.11 authentication, which is a low-level authentication mechanism. Link verification is performed when an STA associates with an AP over 802.11, which is earlier than access authentication. Before accessing a WLAN, the STA must be authenticated over 802.11. 802.11 authentication marks the beginning of the handshake process when an STA accesses a WLAN and the first step for network connection.

The IEEE 802.11 standard defines two approaches to link authentication:

- Open-system link authentication
- Shared-key link authentication

Working Principle

↘ Open-System Link Authentication

Open-system link authentication allows all users to access a WLAN. In this sense, no data protection is provided, which means that no authentication is performed. In other words, if the authentication mode is set to open-system authentication, all STAs that request authentication can pass the authentication.

Open-system link authentication comprises two steps:

Step 1: An STA requests authentication. The STA sends an authentication request that contains the ID (usually the MAC address) of the STA.

Step 2: An AP returns the authentication result. The AP sends an authentication response that contains information indicating whether the authentication succeeds or fails. If the authentication succeeds, the STA and AP pass the bidirectional authentication.

Figure 1-5

↘ Shared-key Link Authentication

Shared-key link authentication is another authentication mechanism in addition to the open-system link authentication. Shared-key link authentication requires that the same shared key be configured for an STA and an AP. The shared-key link authentication can be configured only in static WEP encryption whereas the open-system link authentication is available in all the other modes.

The process of shared-key link authentication is as follows:

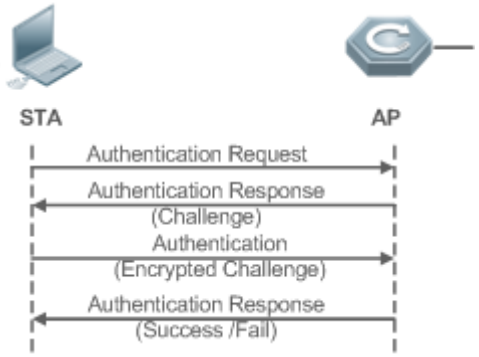
Step 1: An STA sends an authentication request to an AP.

Step 2: The AP generates a Challenge packet (a string) at random and sends the packet to the STA.

Step 3: The STA copies the received string to a new message, encrypts the message with a key and then sends the encrypted message to the AP.

Step 4: After receiving the message, the AP decrypts the message with the key, and then compares the decrypted string with the string sent to the STA. If the two strings are the same, it indicates that the STA has the same shared key as that on the AP and the shared-key authentication succeeds; otherwise, the shared-key authentication fails.

Figure 1-6



1.3.2 Access Authentication

Access authentication is a solution that enhances WLAN security.

After an STA is associated with an AP, whether the STA can use the service provided by the AP depends on the result of access authentication. If the STA passes the authentication, the AP enables the logical port for the STA; otherwise, the STA is not allowed to access the WLAN.

The IEEE 802.11 standard defines two access authentication approaches:

- PSK access authentication
- 802.1X access authentication

Working Principle

PSK Access Authentication

Pre-shared Key (PSK) is an 802.11i authentication mode, which performs authentication with pre-defined static keys. This authentication approach requires that an STA and an AP be configured with the same pre-shared key. If their keys are the same, the PSK access authentication succeeds; otherwise, the PSK access authentication fails.

802.1X Access Authentication

802.1X is a port-based network access control protocol. This authentication approach is used to authenticate and control the STAs at the port level. STAs connected to the ports can access resources in a WLAN if they pass the authentication; otherwise, the STAs cannot access resources in the WLAN.

A WLAN system with the 802.1X authentication function must provide the following elements to implement port-based authentication and authorization:

- Authentication client

Authentication client is generally installed on the STA. When the user wants to access the network, he activates the client program and enters the user name and password. Then, the client program sends a connection request.

- Authenticator

An authenticator means an AP or a communication device functioning as an AP. It is responsible for uploading and pushing user authentication information and enables or disables a port based on the authentication result.

- Authentication server

The authentication server checks whether a user has the right to use the services provided by the network system based on his identification information (user name and password), and enables or disables a port to the authentication system based on the authentication result.

MAB authentication uses a MAC address as the username to initiate a request to the authentication server. Therefore, it is not necessary for the terminal to install the client.

1.3.3 Wireless Data Encryption

Compared with a wired network, a wireless network is prone to greater security risks. Within an area, all WLAN devices share the same transmission medium and any device can receive data from all the other devices. This feature poses threat to WLAN data.

The IEEE 802.11i protocol defines the following encryption algorithms:

- WEP encryption
- TKIP encryption
- AES encryption

Working Principle

WEP Encryption

Wired Equivalent Privacy (WEP) is a data encryption mode specified in the original IEEE 802.11 standard, and is the basis for WLAN security authentication and encryption. WEP is used to promote the privacy of data exchanged between authorized users in a WLAN and prevent the data from being stolen.

WEP uses the RC4 algorithm to promote data privacy and implements authentication by using a shared key. WEP does not specify a key management scheme. Generally, keys are configured and maintained manually. WEP that does not provide a key distribution mechanism is called manual WEP or static WEP.

A WEP encrypted key may contain 64 bits or 128 bits. The 24-bit Initialization Vector (IV) is generated by the system. Therefore, a shared key to be configured on an AP and an STA consists of only 40 bits or 104 bits. In practice, the 104-bit WEP keys are widely used to replace the 40-bit WEP keys. WEP using 104-bit keys are called WEP-104. Although WEP-104 increases the security of WEP encryption, WEP encryption is prone to security risks due to limitations of the RC encryption algorithm and statically configured keys. WEP encryption cannot ensure the confidentiality and integrity of data or access authentication.

↘ TKIP Encryption

Temporal Key Integrity Protocol (TKIP) is a temporary makeshift solution created by the IEEE 802.11 organization for fixing the WEP encryption mechanism. Like WEP encryption, TKIP encryption also uses the RC4 algorithm. But compared with WEP encryption, TKIP encryption can provide much safer protection for WLAN services in the following aspects:

A static WEP key is manually configured and all users within the same service area share the same key. A TKIP key is generated through dynamic negotiation, and each packet has a unique key.

– TKIP increases the key length from 40 bits to 128 bits, and the IV length from 24 bits to 48 bits, thus improving the security of WEP encryption.

– TKIP supports Message Integrity Check (MIC) and the replay prevention function.

↘ AES Encryption

The Counter mode with CBC-MAC Protocol (AES-CCMP) is the most advanced wireless security protocol oriented to the public.

The IEEE 802.11i standard requires that CCMP be used to provide four security services, namely, authentication, confidentiality, integrity, and replay prevention. CCMP uses the 128-bit Advanced Encryption Standard (AES) to implement confidentiality and uses the CBC-MAC to ensure data integrity and authentication.

As a new advanced encryption standard, AES uses the symmetrical block encryption technology to provide better encryption performance than the RC4 algorithm in WEP/TKIP. It is the new-generation encryption technology that replaces WEP and brings more powerful security protection for WLANs.

The IEEE 802.11r standard requires that CCMP be used to encrypt EAPOL packets. Therefore, before enabling the 802.11r function, configure the AES-CCMP encryption mode.

1.3.4 WPA3 Authentication

Compared with WPA2 PSK mode, the WPA3 Personal mode have the new SAE interaction, which is borne over authentication packets. When an AP/AC interacts with an STA, there are only one pair of authentication packets (two packets) in WPA2 PSK mode and two pairs of authentication packets (four packets) in WPA3 Personal mode. In the SAE process, parameters interacted using public and private keys and various random numbers are carried in SAE packets and a PMK is negotiated using passwords of the AP/AC and the STA. The PMK is then used for 4-way handshake. In WPA2 mode, PMKs used for 4-way handshake map to passwords and therefore PMKs can be cracked via dictionary attacks. 256-bit random numbers are added to the SAE interaction and cracking is impossible. Therefore, the restriction that the password length cannot be shorter than 8 characters is eliminated in WPA3 Personal mode.

In WPA3 Enterprise mode, the overall security is improved from 128-bit encryption to 192-bit encryption. The unicast key length increases from 128 bits to 256 bits, the multicast encryption suite is changed from CCMP to GCMP-256, and the multicast management suite is changed from CCMP to BIP-GMAC-256.

1.4 Configuration

Configuration	Description and Command	
Configuring Static WEP	(Mandatory) It is used to enable static WEP encryption.	
	security static-wep-key encryption	Enables static WEP for a WLAN and configures a static WEP key.
	(Optional) It is used to configure the link authentication mode.	
	security static-wep-key authentication	Configures the link authentication mode of static WEP.
Configuring WPA Authentication	(Mandatory) It is used to enable WPA authentication.	
	security wpa	Configures WPA authentication.
	security wpa ciphers	Configures the encryption mode of WPA authentication.
	security wpa akm	Configures the access authentication mode for WPA authentication.

Configuration	Description and Command	
	(Optional) It is used to configure a shared key for WPA PSK authentication.	
	security wpa akm psk set-key	Configures a shared key for WPA PSK authentication.
Configuring RSN Authentication	(Mandatory) It is used to enable RSN authentication.	
	security rsn	Configures RSN authentication.
	security rsn ciphers	Configures the encryption mode for RSN authentication.
	security rsn akm	Configures the access authentication mode for RSN authentication.
	(Optional) It is used to configure a shared key for RSN PSK authentication.	
	security rsn akm psk set-key	Configures a shared key for RSN PSK authentication.
Configuring MAB Authentication	(Optional) It is used to configure MAB authentication.	
	dot1x-mab	Enables MAB authentication.
Configuring Authentication Parameters	(Optional) It is used to configure key interaction parameters and the jitter prevention time in WEB authentication.	
	authtimeout forbidcount	Configures the association forbidding count after four-way handshake key interaction fails.
	authtimeout forbidtime	Configures the association forbidding interval after four-way handshake key interaction fails.
	authtimeout groupcount	Configures the multicast key negotiation packet re-transmission count.
	authtimeout grouptime	Configures the timeout duration of multicast key negotiation packets.
	authtimeout paircount	Configures the uncast key negotiation packet re-transmission count.
	authtimeout pairtime	Configures the timeout duration of unicast key negotiation packets.
	webauth prevent-jitter	Configures the jitter prevention time of WEB authentication.
Configuring WPA3	**security wpa3 dot11r**	Enables or disables the WPA3 802.11r function.
	security wpa3 mode	Sets the WPA3 mode.
	security wpa3 personal passphrase	Sets a password for the WPA3 Personal mode.

1.4.1 Configuring Static WEP

Configuration Effect

- Enable static WEP encryption and provide WEP encryption protection for WLAN data.
- Configure the link authentication mode.

Notes

- The link authentication mode must be configured after static WEP encryption is enabled.
- In the security mode of a WLAN, static WEP encryption cannot be configured together with other authentication encryption.
- Only one WLAN can be configured with static WEP encryption

Configuration Steps

↘ Enabling Static WEP

- Mandatory.
- Enable static WEP encryption in WLAN security configuration mode on the AC.

Command	**security static-wep-key encryption** *key-length* { **ascii** | **hex** } *key-index key*
Parameter Description	*key-length*: Specifies the key length, which can be 40 bits or 104 bits. **ascii**: Specifies that the WEP key is ASCII code. **hex**: Specifies that the WEP key is hexadecimal code. *key-index*: Specifies the key index, ranging from 1 to 4. *key*: Specifies key data.
Defaults	Static WEP is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to configure a static WEP key and enable static WEP. This command can be configured repeatedly, but only the last configuration takes effect. The key length must be the same as the *key-length* parameter in the command.

↘ Configuring the Link Authentication Mode

- (Optional) The default link authentication mode is open-system link authentication. This command can be used to configure shared-key link authentication.
- Enable static WEP encryption in security configuration mode on the AC.
- The link authentication mode can be configured only after static WEP encryption is enabled. After configuring the sharedkey link authentication mode, set the link authentication mode to shared key link authentication on the STA; otherwise, the STA cannot access the WLAN.

Command	**security static-wep-key authentication** { **open** | **share-key** }
Parameter	**open**: Configures open-system link authentication.

Description	**share-key**: Configures shared key link authentication.
Defaults	An STA accesses a WLAN by using open-system link authentication by default.
Command Mode	WLAN security configuration mode
Usage Guide	Configure the link authentication mode after configuring a static WEP key. The link authentication mode cannot be configured for other security configuration modes than static WEP.

Verification

Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring Static WEP Encryption and Using Shared-Key Link Authentication for WLAN 1

Scenario Figure 1-7	 In a Fit AP environment, configure WLAN 1 on the AC and configure the security policies 1 as follows: 1. Enable static WEP encryption. 2. Configure shared-key link authentication.
Configuration Steps	● Access the security configuration mode of WLAN 1. ● Enable static WEP encryption and configure a WEP key. ● Set the link authentication mode to shared-key link authentication.
AC	`Ruijie(config)#wlansec 1` `Ruijie(config-wlansec)#security static-wep-key encryption 40 ascii 1 12345` `Ruijie(config-wlansec)#security static-wep-key authentication share-key`
Verification	Run the **show running-config	begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	`Ruijie#show running-config	begin wlansec 1` `wlansec 1` ` security static-wep-key encryption 40 ascii 1 12345`

	security static-wep-key authentication share-key !

Common Errors

- The configured key length is inconsistent with the specified key length.
- Static WEP is configured for multiple WLANs.
- The link authentication mode is configured before static WEP is enabled.

1.4.2 Configuring WPA Authentication

Configuration Effect

- Enable WPA authentication for a WLAN.
- Specify the access authentication mode and encryption mode in WPA authentication.

Notes

- When WPA authentication is used, the encryption mode and access authentication mode must also be configured.
- If the access authentication mode is set to PSK, a PSK key must be configured.
- In the security mode of a WLAN, WPA authentication cannot be configured with WEP authentication.

Configuration Steps

↘ Configuring WPA Authentication

- Mandatory.
- Enable WPA authentication in WLAN security configuration mode on the AC.

Command	**security wpa** { **enable** | **disable** }
Parameter Description	**enable**: Enables WPA authentication. **disable**: Disables WPA authentication.
Defaults	WPA authentication is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	The encryption mode and access authentication mode can be configured in WPA authentication only after WPA authentication is enabled; otherwise, the configuration does not take effect. When WPA authentication is used, the encryption mode and access authentication mode must also be configured. If either the encryption mode or the access authentication mode is configured or neither of them is configured, STAs cannot access a WLAN.

↘ Configuring the Encryption Mode of WPA Authentication

- Mandatory.

- It is configured in WLAN security configuration mode on the AC.
- The encryption mode of WPA authentication can be configured only after WPA authentication is enabled. The AES and TKIP encryption modes can be enabled at the same time in WLAN security configuration mode. After an encryption mode is configured for a WLAN, communication data between an STA and the WLAN is protected by the corresponding encryption mode.

Command	**security wpa ciphers** { **aes** | **tkip** } { **enable** | **disable** }
Parameter Description	**aes**: Configures the AES encryption mode. **tkip**: Configures the TKIP encryption mode. **enable**: Enables the encryption mode of WPA authentication. **disable**: Disables the encryption mode of WPA authentication.
Defaults	No encryption mode is configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to enable an encryption mode of WPA authentication, which can be AES or TKIP. The AES and TKIP encryption modes can be enabled at the same time in WLAN security configuration mode.

Configuring the Access Authentication Mode of WPA authentication

- Mandatory.
- It is configured in WLAN security configuration mode on the AC.
- The access authentication mode can be configured only after WPA authentication is enabled. Only one access authentication mode can be enabled for a WLAN in security configuration mode. An STA can access a WLAN that is enabled with access authentication only after passing the access authentication.

Command	**security wpa akm** { **psk** | **802.1x** } { **enable** | **disable** }
Parameter Description	**psk**: Sets the access authentication mode to pre-shared key authentication. **802.1x**: Sets the access authentication mode to 802.1X authentication. **enable**: Enables the access authentication mode of WPA authentication. **disable**: Disables the access authentication mode of WPA authentication.
Defaults	No access authentication mode is configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	The access authentication mode can be configured only after WPA authentication is enabled. Only one access authentication mode can be enabled for a WLAN in security configuration mode.

Configuring a Shared Key for WPA Authentication

- (Optional) It must be configured when WPA PSK authentication is enabled.
- It is configured in WLAN security configuration mode on the AC.

Command	**security wpa akm psk set-key** { **ascii** *ascii-key* | **hex** *hex-key* }
Parameter Description	**ascii**: Specifies that the PSK key is ASCII code. *ascii-key*: Specifies a key in the ASCII format, consisting of 8 to 63 ASCII characters. **hex**: Specifies that the PSK key is hexadecimal code. *hex-key*: Specifies a key in the hexadecimal format, consisting of 64 characters.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	This shared key takes effect only when PSK authentication is enabled. A key in the ASCII format consists of 8 to 63 characters. A key in the hexadecimal format consists of 64 characters.

Verification

Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring WPA PSK Authentication, AES Encryption and Key 12345678 for WLAN 1

Scenario Figure 1-8	 In a Fit AP environment, configure the security policies of WLAN 1 on the AC as follows: 1. Configure WPA PSK authentication. 2. Configure the AES encryption mode. 3. Configure the shared key 12345678.
Configuration Steps	● Access security configuration mode of WLAN 1. ● Enable WPA authentication. ● Configure the AES encryption mode for WPA authentication. ● Configure the PSK access authentication mode for WPA authentication. ● Configure the PSK key 12345678.
AC	`Ruijie(config)#wlansec 1` `Ruijie(config-wlansec)#security wpa enable` `Ruijie(config-wlansec)#security wpa ciphers aes enable`

	Ruijie(config-wlansec)#security wpa akm psk enable Ruijie(config-wlansec)#security wpa akm psk set-key ascii 12345678
Verification	Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	Ruijie#show running-config | begin wlansec 1 wlansec 1 security wpa enable security wpa ciphers aes enable security wpa akm psk enable security wpa akm psk set-key ascii 12345678 !

Common Errors

- The WLAN has been enabled with other encryption and authentication modes (such as WEP).
- A WPA encryption mode is configured before WPA authentication is enabled in WLAN security configuration mode.
- An access authentication mode is configured before WPA authentication is enabled in WLAN security configuration mode.
- If an access authentication mode is enabled in WLAN security configuration mode, no other access authentication mode can be configured.
- A WPA PSK key is configured before WPA authentication is enabled.
- The ASCII key consists of less than 8 characters or more than 63 characters.
- The hexadecimal key does not consist of 64 characters.

1.4.3 Configuring RSN Authentication

Configuration Effect

- Enable RSN authentication for a WLAN.
- Specify the access authentication mode and encryption mode in RSN authentication.

Notes

- When RSN authentication is used, the encryption mode and access authentication mode must also be configured.
- If the access authentication mode is set to PSK, a PSK key must be configured.
- In the security mode of a WLAN, RSN authentication cannot be configured with WEP authentication.

Configuration Steps

Configuring RSN Authentication

- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC.

Command	**security rsn** { **enable** | **disable** }
Parameter Description	**enable**: Enables RSN authentication. **disable**: Disables RSN authentication.
Defaults	RSN authentication is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	The encryption mode and access authentication mode can be configured in RSN authentication only after RSN authentication is enabled; otherwise, the configuration does not take effect. When RSN authentication is used, the encryption mode and access authentication mode must also be configured. If either the encryption mode or the access authentication mode is configured or neither of them is configured, STAs cannot access a WLAN.

Configuring the Encryption Mode for RSN Authentication

- Mandatory.
- It is configured in WLAN security configuration mode on the AC.
- The encryption mode in RSN authentication can be configured only after RSN authentication is enabled. The AES and TKIP encryption modes can be enabled at the same time in WLAN security configuration mode. After an encryption mode is configured for a WLAN, communication data between an STA and the WLAN is protected by the corresponding encryption mode.

Command	**security rsn ciphers** { **aes** | **tkip** } { **enable** | **disable** }
Parameter Description	**aes**: Configures the AES encryption mode. **tkip**: Configures the TKIP encryption mode. **enable**: Enables the encryption mode for RSN authentication. **disable**: Disables the encryption mode for RSN authentication.
Defaults	No encryption mode is configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to enable an encryption mode for RSN authentication, which can be AES or TKIP. The AES and TKIP encryption modes can be enabled at the same time in WLAN security configuration mode.

Configuring the Access Authentication Mode for RSN Authentication

- Mandatory.

- It is configured in WLAN security configuration mode on the AC.
- The access authentication mode in RSN authentication can be configured only after RSN authentication is enabled. Only one access authentication mode can be enabled for a WLAN in security configuration mode. An STA can access a WLAN that is enabled with access authentication only after passing the access authentication.

Command	**security rsn akm** { **psk** | **802.1x** } { **enable | disable** }
Parameter Description	**psk**: Sets the access authentication mode to pre-shared key authentication. **802.1x**: Sets the access authentication mode to 802.1X authentication. **enable**: Enables the access authentication mode for RSN authentication. **disable**: Disables the access authentication mode for RSN authentication.
Defaults	No access authentication mode is configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	The access authentication mode can be configured only after RSN authentication is enabled. Only one access authentication mode can be enabled for a WLAN in security configuration mode.

Configuring a Shared Key for RSN Authentication

- (Optional) It must be configured when RSN PSK authentication is enabled.
- It is configured in WLAN security configuration mode on the AC.

Command	**security rsn akm psk set-key** { **ascii** *ascii-key* | **hex** *hex-key* }
Parameter Description	**ascii**: Specifies that the PSK key is ASCII code. *ascii-key*: Specifies a key in the ASCII format, consisting of 8 to 63 ASCII characters. **hex**: Specifies that the PSK key is hexadecimal code. *hex-key*: Specifies a key in the hexadecimal format, consisting of 64 characters.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	This shared key takes effect only when PSK authentication is enabled. A key in the ASCII format consists of 8 to 63 characters. A key in the hexadecimal format consists of 64 characters.

Verification

Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring RSN PSK Authentication, AES Encryption and Key 12345678 for WLAN 1

Scenario **Figure 1-9**	 In a Fit AP environment, configure the security policies of WLAN 1 on the AC as follows: 1. Configure RSN PSK authentication. 2. Configure the AES encryption mode. 3. Configure the shared key to 12345678.
Configuration Steps	● Access security configuration mode of WLAN 1. ● Enable RSN authentication. ● Configure the AES encryption mode for RSN authentication. ● Configure the PSK access authentication mode for RSN authentication. ● Configure the PSK key 12345678.
AC	`Ruijie(config)#wlansec 1` `Ruijie(config-wlansec)#security rsn enable` `Ruijie(config-wlansec)#security rsn ciphers aes enable` `Ruijie(config-wlansec)#security rsn akm psk enable` `Ruijie(config-wlansec)#security rsn akm psk set-key ascii 12345678`
Verification	Run the **show running-config	begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	`Ruijie#show running-config	begin wlansec 1` `wlansec 1` ` security rsn enable` ` security rsn ciphers aes enable` ` security rsn akm psk enable` ` security rsn akm psk set-key ascii 12345678` `!`

Common Errors

- The WLAN has been enabled with other encryption and authentication modes (such as WEP).
- An RSN encryption mode is configured before RSN authentication is enabled in WLAN security configuration mode.
- An access authentication mode is configured before RSN authentication is enabled in WLAN security configuration mode.
- If an access authentication mode is enabled in WLAN security configuration mode, no other access authentication mode can be configured.
- An RSN PSK key is configured before RSN authentication is enabled.
- The ASCII key consists of less than 8 characters or more than 63 characters.
- The hexadecimal key does not consist of 64 characters.

1.4.4 Configuring RSN 802.11r

Configuration Effect

- If the 802.11r function is enabled for a WLAN, the 802.1x authentication and 4-way handshake are not required during fast roaming, thereby reducing network delay caused by roaming.

Notes

- 802.11r can be independently configured in RSN and WPA3.
- The RSN 802.11r function can be enabled only when the following conditions are met:
    1. RSN authentication is enabled.
    2. WPA authentication is disabled, that is, WPA and RSN cannot be enabled simultaneously.
    3. The access authentication mode (AKM) is configured as PSK or 802.1x.
    4. AES encryption is enabled.
    5. TKIP encryption is disabled, that is, AES and TKIP cannot be enabled simultaneously.
- For roaming between ACs with the same SSID, WLAN IDs of the ACs must be the same.
- The 802.1x LEAP authentication mode is not supported.

Configuration Steps

↘ Configuring RSN Authentication

- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC.

Command	**security rsn** { **enable** | **disable** }
Parameter Description	**enable**: Enables RSN authentication. **disable**: Disables RSN authentication.

Defaults	RSN authentication is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	The encryption mode and access authentication mode can be configured for RSN authentication only after RSN authentication is enabled; otherwise, the configuration does not take effect. When RSN authentication is used, the encryption mode and access authentication mode must also be configured. If either the encryption mode or the access authentication mode is configured or neither of them is configured, STAs cannot access a WLAN.

Configuring the Encryption Mode for RSN Authentication

- Mandatory.
- It is configured in WLAN security configuration mode on the AC.
- The encryption mode for RSN authentication can be configured only after RSN authentication is enabled. The AES and TKIP encryption modes can be enabled at the same time in WLAN security configuration mode. After a data encryption mode is configured for a WLAN and a STA accesses the WLAN, communication data of the STA is protected in the corresponding encryption mode.

Command	**security rsn ciphers** { **aes** | **tkip** } { **enable** | **disable** }
Parameter Description	**aes**: Configures the AES encryption mode. **tkip**: Configures the TKIP encryption mode. **enable**: Enables the encryption mode for RSN authentication. **disable**: Disables the encryption mode for RSN authentication.
Defaults	No encryption mode is configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to enable the AES or TKIP encryption mode for RSN authentication. To use the 802.11r function, AES encryption must be configured. In addition, TKIP encryption must be disabled. TKIP encryption is disabled by default.

Configuring the Access Authentication Mode for RSN Authentication

- Mandatory.
- It is configured in WLAN security configuration mode on the AC.
- The access authentication mode for RSN authentication can be configured only after RSN authentication is enabled. Only one access authentication mode can be enabled for a WLAN in security configuration mode. An STA can access a WLAN with access authentication enabled only after passing the access authentication.

Command	**security rsn akm** { **psk** | **802.1x** } { **enable | disable** }
Parameter Description	**psk**: Sets the access authentication mode to pre-shared key authentication. **802.1x**: Sets the access authentication mode to 802.1X authentication. **enable**: Enables the access authentication mode for RSN authentication.

	disable: Disables the access authentication mode for RSN authentication.
Defaults	No access authentication mode is configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	The access authentication mode can be configured only after RSN authentication is enabled. Only one access authentication mode can be enabled for a WLAN in security configuration mode.

Configuring a Shared Key for RSN Authentication

- (Optional) It must be configured when RSN PSK authentication is enabled.
- It is configured in WLAN security configuration mode on the AC.

Command	**security rsn akm psk set-key** { **ascii** *ascii-key* | **hex** *hex-key* }
Parameter Description	**ascii**: Specifies that the PSK key is an ASCII code. *ascii-key*: Specifies a key in the ASCII format, consisting of 8 to 63 characters. **hex**: Specifies that the PSK key is a hexadecimal code. *hex-key*: Specifies a key in the hexadecimal format, consisting of 64 characters.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	The shared key takes effect only when PSK authentication is enabled. A key in the ASCII format consists of 8 to 63 characters. A key in the hexadecimal format consists of 64 characters.

Enabling RSN 802.11r

- Optional

Command	**security rsn dot11r {disable | enable}**
Parameter Description	**disable**: Disables 802.11r. **enable**: Enables 802.11r.
Defaults	The 802.11r function is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	To manually enable the 802.11r function, a judgment is made based on the conditions. For details about the conditions, see "Notes." This command is valid only when AKM (802.1x or PSK) is enabled. This command is valid only when AES encryption is enabled.

Modifying 802.11r Re-association Timeout Duration

- (Optional) This command is used to configure the re-association timeout duration in the unit of seconds (that is, the maximum interval for a client to send an association request after the client authentication is completed).

Command	**security rsn dot11r reassoc-timeout** *timeout*

Parameter Description	*timeout:* The range is from 1 to 120. The unit is second.
Defaults	The re-association timeout duration is 20 seconds by default.
Command Mode	WLAN security configuration mode
Usage Guide	This command takes effect only after the 802.11r function is enabled. If the client does not initiate an re-association request within the re-association timeout duration, the roaming is stopped.

Verification

Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

↘ Configuring RSN PSK Authentication, AES Encryption, and Key 12345678 and Enabling 802.11r for WLAN 1

Scenario **Figure 1-10**	 In a fit AP environment, configure the following security policies for WLAN 1 on the AC: 1. Configure RSN PSK authentication. 2. Configure AES data encryption. 3. Set the shared key to 12345678. 4. Enable 802.11r.
Configuration	● Enter the security configuration mode of WLAN 1.

Steps	● Enable RSN authentication. ● Set the data encryption mode for RSN authentication to AES. ● Set the access authentication mode for RSN authentication to PSK. ● Set the PSK key to 12345678. ● Enable 802.11r.
AC	`Ruijie(config)#wlansec 1` `Ruijie(config-wlansec)#security rsn enable` `Ruijie(config-wlansec)#security rsn ciphers aes enable` `Ruijie(config-wlansec)#security rsn akm psk enable` `Ruijie(config-wlansec)#security rsn akm psk set-key ascii 12345678` `Ruijie(config-wlansec)#security rsn dot11r enable`
Verification	Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	`Ruijie#show running-config | begin wlansec 1` `wlansec 1` ` security rsn enable` ` security rsn ciphers aes enable` ` security rsn akm psk enable` ` security rsn akm psk set-key ascii 12345678` ` security rsn dot11r enable` `!`

Common Errors

- 802.11r is enabled while RSN authentication is disabled or both of RSN and WPA are enabled .
- 802.11r is enabled while the authentication mode (802.1x or PSK) is not configured.
- 802.11r is enabled while AES encryption is disabled or both of AES encryption and TKIP encryption are enabled.
- The SSIDs of ACs are the same but the WLAN IDs are different, causing FT roaming failures.

1.4.5 Configuring WPA3 802.11r

Configuration Effect

- If the 802.11r function is enabled for a WLAN, the 802.1x authentication and 4-way handshake are not required during fast roaming, thereby reducing network latency caused by roaming handover.

Notes

- 802.11r can be independently configured in RSN and WPA3.

Configuration Steps

Enabling WPA3 802.11r

- Mandatory.
- Set the WPA3 mode to **Personal** or **Enterprise** before enabling the 802.11r function.

Command	**security wpa3 dot11r** { **enable** | **disable** }
Parameter Description	**enable**: Enables the 802.11r function in WPA3 mode. **disable**: Disables the 802.11r function in WPA3 mode.
Defaults	The 802.11r function is disabled in WPA3 mode by default.
Command Mode	WLAN security configuration mode
Usage Guide	Set the WPA3 mode to **Personal** or **Enterprise** before using the 802.11r fast roaming function in WPA3 mode.

1.4.6 Configuring MAB Authentication

Configuration Effect

- Enable MAB authentication for a WLAN.

Notes

- In security mode of a WLAN, MAB authentication cannot be configured together with 802.1X access authentication or WEP authentication, but can be configured together with PSK authentication.

Configuration Steps

Configuring MAB Authentication

- Mandatory.
- Enable MAB authentication in WLAN security configuration mode on the AC.
- Run the **dot1x-mab** command to enable MAB authentication or run the **no dot1x-mab** command to disable MAB authentication.
- MAB authentication can be configured independently, without RSN or WPA authentication enabled. MAB authentication can be used together with PSK access authentication, but cannot be used together with 802.1X access authentication.

Command	**dot1x-mab**

Parameter Description	**no**: Disables MAB authentication.
Defaults	MAB authentication is not configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to enable MAB authentication. MAB authentication can be used together with PSK access authentication, but cannot be used together with 802.1X access authentication.

Verification

Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring MAB Authentication for WLAN 1

Scenario Figure 1-11	 In a Fit AP environment, configure the security policies of WLAN 1 on the AC as follows: 1. Configure MAB authentication.
Configuration Steps	● Access the security configuration mode of WLAN 1. ● Enable MAB authentication.
AC	`Ruijie(config)#wlansec 1` `Ruijie(config-wlansec)#dot1x-mab`
Verification	Run the **show running-config	begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	`Ruijie#show running-config	begin wlansec 1` `wlansec 1` ` dot1x-mab` `!`

Common Errors

- The WLAN has been enabled with other encryption and authentication modes (such as WEP).
- If 802.1X access authentication is enabled in WLAN security configuration mode, MAB authentication cannot be configured.

1.4.7 Configuring Authentication Parameters

Configuration Effect

- Configure key interaction parameters.
- Configure the jitter prevention time in WEB authentication.

Notes

- Key interaction parameters take effect only in PSK or 802.1X authentication.
- The jitter prevention time in WEB authentication can be configured only after WEB authentication is enabled.

Configuration Steps

↘ Configuring Key Interaction Parameters

- Optional. Generally, it is unnecessary to configure key interaction parameters. It is recommended to set the packet re-transmission count and timeout duration to great values for a poor WLAN environment.
- It is configured in WLAN security configuration mode on the AC.

Command	**authtimeout** { **forbidcount** *count* | **forbidtime** *time* | **groupcount** *count* | **grouptime** *timeout* | **paircount** *count* | **pairtime** *timeout* }
Parameter Description	**forbidcount** *count*: Configures the association forbidding count after four-way handshake key interaction fails.. **forbidtime** *time*: Configures the association forbidding interval after four-way handshake key interaction fails. **groupcount** *count*: Configures the multicast key negotiation packet re-transmission count. **grouptime** *timeout*: Configures the timeout duration of multicast key negotiation packets. **paircount** *count*: Configures the unicast key negotiation packet re-transmission count. **pairtime** *timeout*: Configures the timeout duration of unicast key negotiation packets.
Defaults	The association is not forbidden after four-way handshake key interaction fails. The default multicast key negotiation packet re-transmission count is 4. The default timeout duration of multicast key negotiation packets is 1200 ms. The default unicast key negotiation packet re-transmission count is 4. The default timeout duration of unicast key negotiation packets is 1200 ms.
Command Mode	WLAN security configuration mode
Usage Guide	Key interaction parameters take effect only in PSK or 802.1X authentication.

Configuring the Jitter Prevention Time of WEB Authentication

- Optional. The default jitter prevention time of WEB authentication is 300 seconds. Users can configure the jitter prevention time based on actual requirements or disable the jitter prevention of WEB authentication by setting the time to 0 seconds.
- It is configured in WLAN security configuration mode on the AC.

Command	**webauth prevent-jitter** *timeout*
Parameter Description	*timeout*: Configures the jitter prevention time of WEB authentication, ranging from 0 to 86400 seconds (the jitter prevention of WEB authentication is disabled when this parameter is set to 0).
Defaults	The default jitter prevention time of WEB authentication is 300 seconds.
Command Mode	WLAN security configuration mode
Usage Guide	The jitter prevention time of WEB authentication can be configured only after WEB authentication is enabled.

Verification

Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring the RSN-PSK + WEB Authentication Mode, the Unicast Key Negotiation Re-transmission Count to 5, and the Jitter Prevention Time of WEB Authentication to 900 Seconds for WLAN 1

Scenario Figure 1-12	 In a Fit AP environment, configure the security policies of WLAN 1 on the AC as follows: 1. Configure RSN PSK authentication. 2. Enable WEB authentication.
Configuration Steps	● Access the security configuration mode of WLAN 1. ● Enable RSN authentication. ● Configure the AES encryption mode for RSN authentication. ● Configure the PSK access authentication mode for RSN authentication. ● Configure the PSK key 12345678. ● Set the unicast key negotiation packet re-transmission count to 5.

	• Configure WEB authentication. • Set the jitter prevention time of WEB authentication to 900 seconds.
AC	`Ruijie(config)#wlansec 1` `Ruijie(config-wlansec)#security rsn enable` `Ruijie(config-wlansec)#security rsn ciphers aes enable` `Ruijie(config-wlansec)#security rsn akm psk enable` `Ruijie(config-wlansec)#security rsn akm psk set-key ascii 12345678` `Ruijie(config-wlansec)#authtimeout paircount 5` `Ruijie(config-wlansec)#webauth` `Ruijie(config-wlansec)#webauth prevent-jitter 900`
Verification	Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	`Ruijie#show running-config | begin wlansec 1` `wlansec 1` ` security rsn enable` ` security rsn ciphers aes enable` ` security rsn akm psk enable` ` security rsn akm psk set-key ascii 12345678` ` webauth prevent-jitter 900` ` webauth` ` authtimeout paircount 5`

Common Errors

- The jitter prevention time of WEB authentication is configured before WEB authentication is enabled.

1.4.8 Configuring Management Frame Encryption

Configuration Effect

- Transmit partial management frames over the air interface in ciphertext format.

Notes

- Only WPA2 supports management frame encryption. If the WLAN uses Open, WEP-40, WEP-104 or WPA (AES or TKIP) for encryption, the management frame encryption function cannot be enabled.
- Not all STAs' OSs support management frame encryption.

Configuration Steps

Configuring RSN Authentication

- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC.

Command	**security rsn** { **enable** | **disable** }
Parameter Description	**enable**: Enables RSN authentication. **disable**: Disables RSN authentication.
Defaults	RSN authentication is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	The encryption mode and access authentication mode can be configured for RSN authentication only after RSN authentication is enabled; otherwise, the configuration does not take effect. When RSN authentication is used, the encryption mode and access authentication mode must also be configured. If either the encryption mode or the access authentication mode is configured or neither of them is configured, STAs cannot access a WLAN.

Configuring the Encryption Mode for RSN Authentication

- Mandatory.
- It is configured in WLAN security configuration mode on the AC.
- The encryption mode for RSN authentication can be configured only after RSN authentication is enabled. The AES and TKIP encryption modes can be enabled at the same time in WLAN security configuration mode. After a data encryption mode is configured for a WLAN and a STA accesses the WLAN, communication data of the STA is protected in the corresponding encryption mode.

Command	**security rsn ciphers** { **aes** | **tkip** } { **enable** | **disable** }
Parameter Description	**aes**: Configures the AES encryption mode. **tkip**: Configures the TKIP encryption mode. **enable**: Enables the encryption mode for RSN authentication. **disable**: Disables the encryption mode for RSN authentication.
Defaults	No encryption mode is configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to enable the AES or TKIP encryption mode for RSN authentication. The AES and TKIP encryption modes can be enabled at the same time in WLAN security configuration mode.

Configuring the Access Authentication Mode for RSN Authentication

- Mandatory.

- It is configured in WLAN security configuration mode on the AC.
- The access authentication mode for RSN authentication can be configured only after RSN authentication is enabled. Only one access authentication mode can be enabled for a WLAN in security configuration mode. An STA can access a WLAN with access authentication enabled only after passing the access authentication.

Command	**security rsn akm** { **psk** | **802.1x** } { **enable | disable** }
Parameter Description	**psk**: Sets the access authentication mode to pre-shared key authentication. **802.1x**: Sets the access authentication mode to 802.1X authentication. **enable**: Enables the access authentication mode for RSN authentication. **disable**: Disables the access authentication mode for RSN authentication.
Defaults	No access authentication mode is configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	The access authentication mode can be configured only after RSN authentication is enabled. Only one access authentication mode can be enabled for a WLAN in security configuration mode.

Configuring a Shared Key for RSN Authentication

- (Optional) It must be configured when RSN PSK authentication is enabled.
- It is configured in WLAN security configuration mode on the AC.

Command	**security rsn akm psk set-key** { **ascii** *ascii-key* | **hex** *hex-key* }
Parameter Description	**ascii**: Specifies that the PSK key is an ASCII code. *ascii-key*: Specifies a key in the ASCII format, consisting of 8 to 63 characters. **hex**: Specifies that the PSK key is a hexadecimal code. *hex-key*: Specifies a key in the hexadecimal format, consisting of 64 characters.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	The shared key takes effect only when PSK authentication is enabled. A key in the ASCII format consists of 8 to 63 characters. A key in the hexadecimal format consists of 64 characters.

Enabling Management Frame Encryption

- Mandatory.
- Enable management frame encryption on an AC.
- Management frame encryption can be configured only after RSN authentication is enabled.

Command	**security pmf** { **mandatory** | **optional | disable** }
Parameter Description	**mandatory**: The client needs to support management frame encryption. **optional**: The client does not need to support management frame encryption. **Disable**: Disables management frame encryption.

Defaults	Management frame encryption is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Enabling RSN-PSK Authentication and Management Frame Encryption for WLAN 1

Scenario Figure 1-13	 In a fit AP environment, configure the following security policies for WLAN 1 on the AC: 1. Configure RSN PSK authentication. 2. Enable management frame encryption.
Configuration Steps	● Enter the security configuration mode of WLAN 1. ● Enable RSN authentication. ● Set the data encryption mode for RSN authentication to AES. ● Set the access authentication mode for RSN authentication to PSK. ● Set the PSK key to 12345678. ● Enable management frame encryption.
AC	`Ruijie(config)#wlansec 1` `Ruijie(config-wlansec)#security rsn enable` `Ruijie(config-wlansec)#security rsn ciphers aes enable` `Ruijie(config-wlansec)#security rsn akm psk enable` `Ruijie(config-wlansec)#security rsn akm psk set-key ascii 12345678` `Ruijie(config-wlansec)#security rsn pmf mandatory`

Verification	Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	`Ruijie#show running-config | begin wlansec 1` `wlansec 1` ` security rsn enable` ` security rsn ciphers aes enable` ` security rsn akm psk enable` ` security rsn akm psk set-key ascii 12345678` ` security rsn pmf mandatory`

Common Errors

- WPA encryption is configured, but management frame encryption cannot be enabled.
- After **mandatory** is specified, an STA cannot go online because the STA does not support management frame encryption.

1.4.9 Configuring WPA3 Authentication

Configuration Effect

- Enable the WPA3 authentication mode on a WLAN.

Notes

- WPA3 is incompatible with WPA. After either of them is enabled, related prompts are displayed on the CLI if you attempt to enable the other one.
- WPA3 is incompatible with WPA2+TKIP. After either of them is enabled, related prompts are displayed on the CLI if you attempt to enable the other one.
- The WPA3 Enterprise mode is incompatible with WPA2. After either of them is enabled, related prompts are displayed on the CLI if you attempt to enable the other one.
- WPA3 relies on management frame encryption, which needs to be enabled first. Related prompts will be displayed on the CLI.

Configuration Steps

↘ Configuring Management Frame Encryption

- Mandatory.
- Perform the configuration in security configuration mode on a WLAN on the AC.

Command	**security pmf** {**optional** | **mandatory** | **disable** }

Parameter Description	**mandatory**: Indicates that the client needs to support management frame encryption. **optional**: Indicates that management frame encryption is optional on the client. **disable**: Disables management frame encryption.
Defaults	Management frame encryption is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	N/A

Configuring the WPA3 Mode

- Mandatory.
- In WLAN security configuration mode, set the WPA3 mode to **Personal**, **Enterprise**, or **Enhanced-Open**.

Command	**security wpa3 mode** { **none | personal** | **enterprise| enhanced-open**}
Parameter Description	**none**: Indicates that WPA3 is disabled. **personal**: Indicates the WPA3 Personal mode, in which shared passwords are used for authentication. **enterprise**: Indicates the WPA3 Enterprise mode, in which 802.1x is used for authentication. **enhanced-open**: Indicates the WPA3 Enhanced-Open mode, in which 802.1x is used for authentication.
Defaults	WPA3 is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	WPA3 is incompatible with WPA, the WPA3 Personal mode is compatible with WPA2, the WPA3 Enterprise mode is incompatible with WPA2, and the WPA3 Enhanced-Open mode is incompatible with WPA and WPA2.

Configuring a Password for the WPA3 Personal Mode

- The configuration is optional if WPA2 PSK authentication is enabled but mandatory when only the WPA3 Personal mode is enabled.
- Configure a password for the WPA3 Personal mode. If no password is configured, WPA2 PSKs are used.

Command	**security wpa3 personal passphrase** { **none** | *p* }
Parameter Description	**none**: Clears the password. *p*: Indicates a password in ASCII code, consisting of 1 to 63 characters.
Defaults	No password is configured for the WPA3 Personal mode by default.
Command Mode	WLAN security configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

↘ Configuring the WPA3 Personal Authentication Mode for WLAN 1 and Setting the Password to 1

Scenario	In a fit AP environment, configure the following security policies for WLAN 1 on the AC: 1. Configure the pure WPA3 Personal authentication mode (RSNA disabled). 2. Set the shared key to 1.
Configuration Steps	● Enter the security configuration mode of WLAN 1. ● Enable management frame encryption. ● Set the password to 1 for the WPA3 Personal mode. ● Set the WPA3 mode to Personal.
AC	`Ruijie(config)#wlansec 1` `Ruijie(config-wlansec)#security pmf optional` `Ruijie(config-wlansec)#security wpa3 personal passphrase 1` `Ruijie(config-wlansec)#security wpa3 mode personal`
Verification	Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	`Ruijie#show running-config | begin wlansec 1` `wlansec 1` ` security pmf optional` ` security wpa3 personal passphrase 1` ` security wpa3 mode personal`

Common Errors

- If you attempt to enable WPA authentication on a WLAN in WPA3 Personal or Enterprise mode, a configuration failure will be displayed.
- If you attempt to enable WPA2 (RSNA) authentication and set the cipher to TKIP in WPA3 Personal mode, a configuration failure will be displayed.
- If you attempt to enable WPA2 (RSNA) authentication on a WLAN in WPA3 Enterprise mode, a configuration failure will be displayed.

1.5 Monitoring

Displaying

Description	Command
Displays security configuration of a WLAN.	**show wlan security** *wlan-id*
Displays security configuration of an STA.	**show wclient security** *mac-address*

2 Configuring WIDS

2.1 Overview

Compared with wired networks, Wireless LAN (WLAN) has unparalleled advantages, such as convenient deployment, flexible use, efficient cost, and easy extension, making it more and more prevalent. However, for the openness of its channels, WLAN is much vulnerable to various network threats, such as rogue access points (APs), Ad-hoc networks, and all types of protocol attacks. Therefore, security becomes a major factor that hinders WLAN development.

Wireless Intrusion Detection System (WIDS) detects vicious STA attacks and invasions in the early stage, which helps network administrators actively observe and defend against the hidden dangers in networks in the first time.

2.2 Applications

Application	Description
Frame Filtering	Facing illegal STAs attempting to access WLAN, WIDS frame filtering helps control STA access.
User Isolation	Facing an STA intending to visit other STAs in WLAN, WIDS user isolation helps isolate their direct communication.
IDS	Facing all kinds of invasion attacks in WLAN, Intrusion Detection System (IDS) helps detect those attacks.
Rogue Detection and Containment	Illegal or rogue devices in WLAN jeopardize STAs and normal services by faking services. Facing it, Rogue detection and containment help monitor and contain them.

2.2.1 Frame Filtering

Scenario

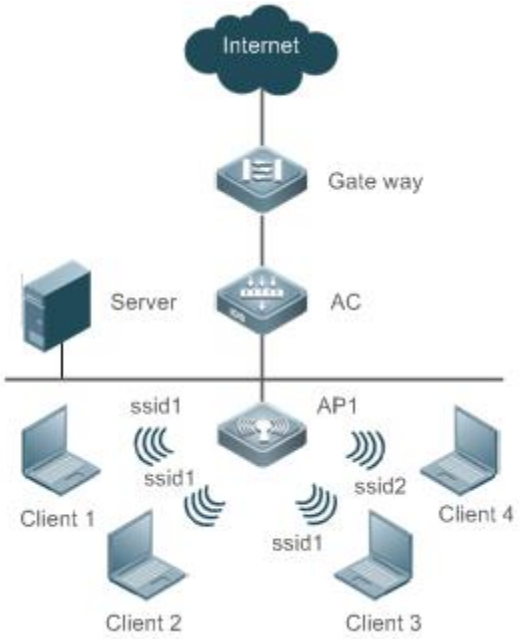
The wireless access control service is provided in WLAN, including allowing specified STAs to access WLAN or specified networks, forbidding STAs from accessing WLAN or specified networks, forbidding low-rate stations (STAs) from accessing WLAN, as well as dynamically controlling network access.

The figure below is an example, assuming that there are the following deployment requirements in the network:

- Allow Client 1 to access WLAN and Client 2 to access SSID 1.
- Prohibit Client 3 from accessing WLAN and Client 4 from accessing SSID 2.
- Filter and kick out low-rate STAs.
- Dynamically control STA access.

The networking topology is shown as follows:

Figure 2-1 Networking Topology of Wireless Access Control



Deployment

The key configuration points for the devices are:

- Add Client 1 to a WIDS whitelist. As a result, Client 1 can access the WLAN service provided by all APs under the AC. Other STAs not in the list cannot.
- Add Client 2 to the SSID 1-based whitelist. As a result, Client 2 can access SSID 1 provided by all APs under the AC. Other STAs not in the list cannot.
- Add Client 3 to a static blacklist. As a result, Client 3 cannot access the WLAN service provided by all APs under the AC.
- Add Client 4 to the SSID 1-based blacklist. As a result, Client 4 cannot access SSID 1 provided by all APs under the AC.
- Configure the low-rate threshold. STAs of an AC with rates less than the threshold will be kicked out.
- Enable the dynamic blacklist function, supporting the IDS function. After the dynamic blacklist function is enabled, any detected attack will be added into the dynamic blacklist. When the blacklist is within aging duration, the listed STAs will continue to be forbidden from communication accessed by the current AP.

2.2.2 User Isolation

Scenario

Layer-2 user isolation is provided in WLAN, including AP-based, AP-SSID based, AC-based, AC-SSID based, and SSID-based.

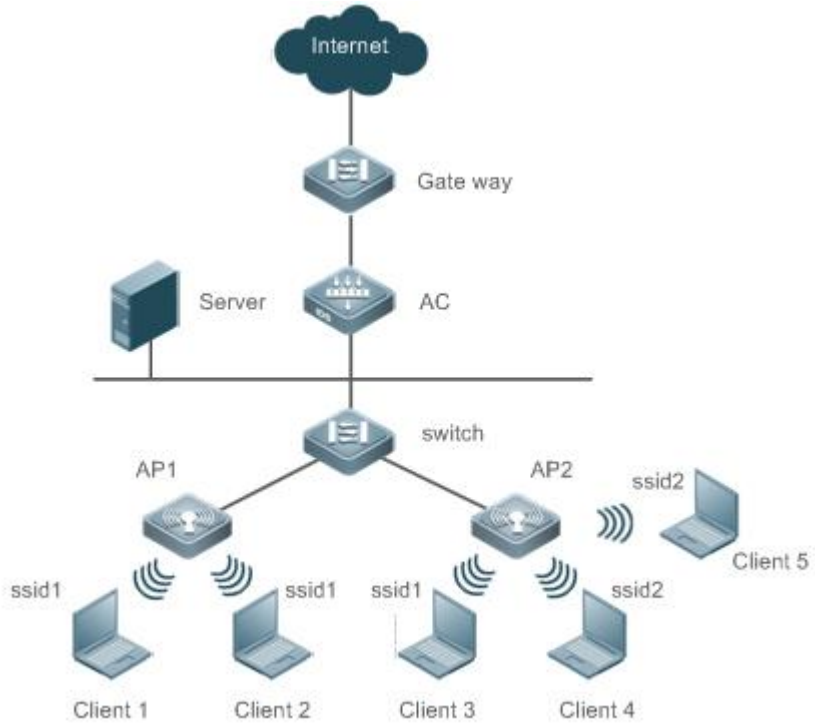
Assuming there are the following deployment requirements in the network:

Client 1 to Client 3 are associated with SSID 1, and Client 4 and Client 5 are associated with SSID 2. SSID 1 and SSID 2 are mapped to the same VLAN. Client 1 to Client 5 are layer-2 users.

- Direct communication cannot be conducted between Client 1 and Client 2, and among Client 3 to Client 5, but can be done among other users.
- Direct communication cannot be conducted between Client 1 and Client 2, and between Client 4 and Client 5, but can be done among other users.
- Direct communication cannot be conducted between Client 1 and Client 3, Client 4 or Client 5, and between Client 2 and Client 3, Client 4 or Client 5, but can be done among other users.
- Direct communication cannot be conducted between Client 3 and Client 1 or Client 2, but can be done among other users.
- Direct communication cannot be conducted among Client 1 to Client 3, but can be done among other users.

The networking topology is shown as follows:

Figure 2-2 Networking Topology of Wireless User Isolation



Deployment

The key configuration points for the devices are:

- Configure AP-based user isolation. As a result, direct communication cannot be conducted between Client 1 and Client 2, and among Client 3 to Client 5.
- Configure AP-SSID based user isolation. As a result, direct communication cannot be conducted between Client 1 and Client 2, and between Client 4 and Client 5.

- Configure AC-based user isolation. As a result, direct communication cannot be conducted between Client 1 or Client 2 and Client 3 to Client 5.
- Configure AC-SSID based user isolation. As a result, direct communication cannot be conducted between Client 3 and Client 1 or Client 2.
- Configure SSID 1-based user isolation. As a result, direct communication cannot be conducted among Client 1, Client 2 and Client 3.

2.2.3 IDS

Scenario

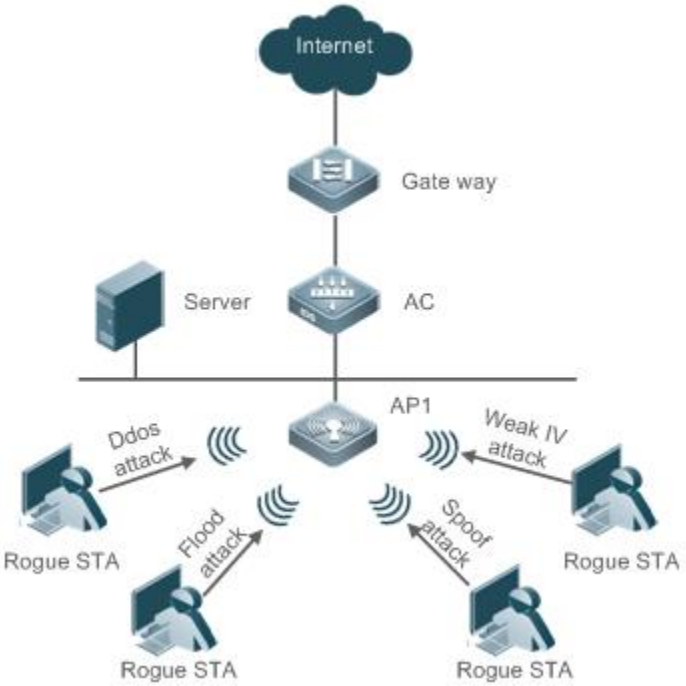
Wireless invasion attacks exist in networks, including Distributed Denial of Service (DDoS), spoofing, flooding, and Weak IV attacks. It requires APs to detect these attacks and carry out countermeasures.

Assuming there are the following deployment requirements in the network:

- DDoS attacks
- Spoofing attacks
- Flooding attacks
- Weak IV attacks

The networking topology is shown as follows:

Figure 2-3 Networking Topology of IDS



Deployment

The key configuration points for the devices are:

- Enable DDoS detection with thresholds specified which perform statistics of ARP, SYN and ICMP attack packets. If any threshold is exceeded, the detection results will be logged, and the users will be blacklisted if the dynamic blacklist is enabled.
- Enable the spoofing detection with related thresholds specified to detect the deauthentication and disassociation packets. If any threshold is exceeded, the detection results will be logged, and the users will be blacklisted if the dynamic blacklist is enabled.
- Enable flooding detection with related thresholds specified to detect the Authentication, Association, Reassociation, Deauthentication, Disassociation, Probe, Null data and Action packets. If any threshold is exceeded, the detection results will be logged, and the users will be blacklisted if the dynamic blacklist is enabled.
- Enable the Weak IV detection with related thresholds specified to detect the IV value of the Web packets. If the number of continuous attacks exceeds the threshold, the detection results will be logged, and the users will be blacklisted if the dynamic blacklist is enabled.

2.2.4 Rogue Detection and Containment

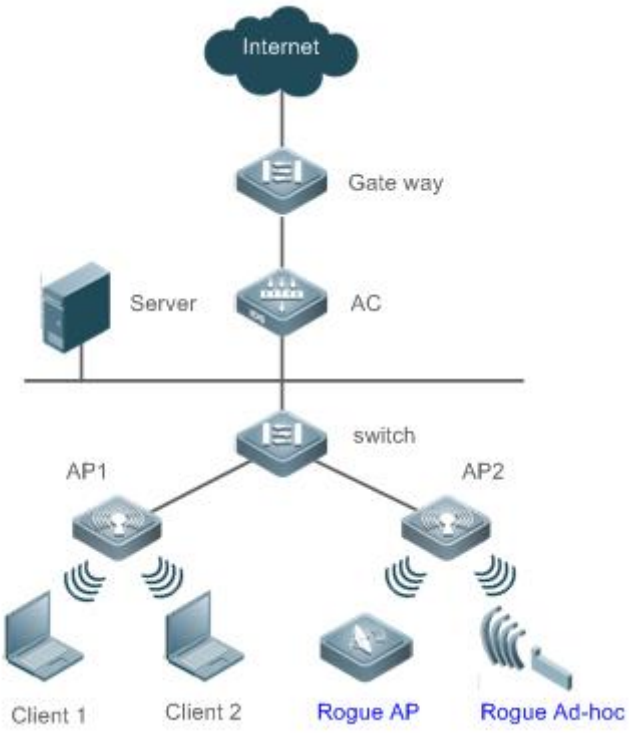
Scenario

Assuming there is the following deployment requirement in the network:

- Rogue AP and Ad-hoc devices exist in network, and detection and containment are required.

The networking topology is shown as follows:

Figure 2-4 Networking Topology of Rogue Detection and Containment



Deployment

The key configuration points for devices are:

- Enable the Monitor or Hybrid mode for a specified AP, and start the detection timer of the AP and obtain detected data at the end of each period.
- Enable the device containment and configure the mode.
- Counter the Rogue APs and Ad-hoc devices regularly based on the containment mode and detected data, preventing users from associating with fake services.

2.3 Features

Basic Concepts

Working Modes

The WIDS has the following working modes:

- Normal mode, providing only the access service
- Monitor mode, providing only the monitoring service
- Hybrid mode, providing both monitoring and access services

IDS Detection Types

The IDS attack detection has the following five types:

- DDoS attack detection, detecting DDoS attacks involving ARP, ICMP and SYN packets
- Flooding attack detection, detecting the flooding attacks involving single-user or multi-user management packets
- Spoofing attack detection, detecting the broadcast disassociation and deauthentication attacks
- Weak IV attack detection, detecting weak vector attacks
- CMCC DoS attack detection

User Isolation Modes

The user isolation has the following five modes:

- AC-based: Communication cannot proceed between layer-2 users of different APs under the same AC.
- AP-based: Communication cannot proceed between layer-2 users under the same AP.
- AC-SSID based: Communication cannot proceed between layer-2 users of different APs under the same AC and in the same WLAN.
- AP-SSID based: Communication cannot proceed between layer-2 users under the same AP and in the same WLAN.
- SSID-based: Communication cannot proceed between layer-2 users in specified WLAN.

Rogue Containment Modes

The Rogue containment has the following four modes:

- Ad-hoc containment mode, containing the Rogue Ad-hoc devices
- Rogue containment mode, containing the Rogue devices with over-limit RSSI
- SSID containment mode, containing illegal devices with the same SSID
- Config containment mode, containing the illegal devices in the static attack list or the SSID blacklist

Fuzzy Containment on Rogue APs

- Fuzzy match is performed based on the SSID of the rogue AP. For example, if the SSID of the local host is RUIJIE-WEB, the rogue AP whose SSID is RU1JIE-WEB can be contained after the fuzzy containment function is enabled.

Detected Devices

The types of detected rogue devices are as follows:

- APs
- Ad-hoc devices
- Unknown STAs

Overview

Feature	Description

Frame filtering	Certain filtering rules are used to filter the packets from STAs for access control.
IDS	Timely discovers and defends against malicious or unintentional attacks in WLAN.
User isolation	Interdicts the insecure access between STAs in WLAN to prevent disclosure of private information.
Rogue detection and containment	Monitors abnormal devices in the whole WLAN, helping the network administrators find hidden dangers in networks. Rogue containment refers to containing Rogue devices by sending fake deauthentication frames to the addresses of Rogue devices in a blacklist.

2.3.1 Frame Filtering

The access control over STAs includes: low-rate filter, whitelist, static blacklist, dynamic blacklist, SSID-based whitelist and SSID-based blacklist.

Working Principle

Low-Rate Filter

The low-rate filter sets a kickout threshold. When the threshold is larger than 0, the filter is enabled. If the STA rate is lower than this threshold, the STA's packets will be discarded and this STA will be disconnected.

Whitelist

The whitelist includes MAC addresses of admitted STAs. If the whitelist function is enabled, only the whistlisted can access the WLAN. Other STAs will be forced to go offline and cannot access the WLAN, so as to reduce the impact of illegal packets in the WLAN.

Static Blacklist

The static blacklist includes MAC address of the denied STAs. If the static blacklist function is enabled, STAs in the blacklist will be forced to go offline and cannot access the network.

Dynamic Blacklist

The dynamic blacklist includes MAC addresses of the denied STAs. You can configure the dynamic blacklist if DDoS attacks are detected. For example, add the MAC address of a detected attacker into the blacklist dynamically to forbid receiving any packet from it, thereby ensuring WLAN security.

SSID-based Whitelist

The SSID-based whitelist includes MAC addresses of the STAs admitted into a WLAN with a specified SSID. You can configure the SSID-based whitelist. If the SSID-based whitelist function is enabled, only the STAs in the whitelist of the specified WLAN are allowed to access. Other STAs cannot access the specified WLAN and online STAs that are not in the whitelist will be forced to go offline, so as to reduce the impact of illegal packets in WLAN.

SSID-based Blacklist

The SSID-based blacklist includes MAC addresses of the STAs denied by a WLAN with a specified SSID. You can configure the SSID-based blacklist. If the SSID-based blacklist function is enabled, STAs in the blacklist will be forced to go offline and cannot access this WLAN.

2.3.2 IDS

In order to timely find and defend against malicious or unintentional attacks in WLAN, IDS supports the detection on multiple attacks. When an attack is detected, an alert or a log will be generated to remind the network administrator of treatment. Based on detected results, the network administrator can timely adjust network configuration to clear the insecure factors in WLAN.

Currently, our devices support the following types of IDS attack detection:

- DDoS attack detection
- Flooding attack detection
- Spoofing attack detection
- Weak IV detection
- CMCC DoS attack detection

Working Principle

↘ DDoS Attack Detection

DDoS attack means that the attackers send a large number of attack packets toward targeted devices in a short period of time (ARP packets, ICMP packets and SYN packets identified currently) so as to affect legal STAs being associated with the attacked device.

DDoS detection function performs statistics for the attacker's packets and determines whether the number of packets per second exceeds the configured threshold. If yes, this result will be logged. If the dynamic blacklist function is enabled, the attacker will be added into the dynamic blacklist.

↘ Flooding Attack Detection

Flooding attack refers to that an attacker sends a large number of packets of the same type in a short period of time, causing the WLAN devices fail to process legal STA requests due to the Rogue flooding.

Flooding attack detection prevents this flooding attack by continuously monitoring the traffic of each device. Within specified time, when the traffic exceeds the upper limit set by the network administrator, this device is deemed to be a flooding attacker and is therefore blocked. Flooding attack detection can be used with the dynamic blacklist function. When attacks are detected, if the dynamic blacklist function is enabled, the STA initiating the attacks will be added into the dynamic blacklist, ensuring no more intrusion by this STA and thus guaranteeing network security.

↘ Spoofing Attack Detection

Spoofing attack refers to that an attacker sends fake packets in the name of another STA. For example, a fake deauthentication packet causes a STA offline.

WIDS performs detection on the broadcast deauthentication and broadcast disassociation packets. When such packet is received, it is immediately defined as a spoofing attack and logged.

Weak IV Attack Detection

Weak IV (Weak Initialization Vector) attack refers to the following attack behavior: when the WLAN uses WEP encryption, an attacker intercepts packets with weak initialization vectors, cracks the shared key and finally steals the encrypted information.

When WLAN uses WEP for encryption, an initialization vector (IV) is generated for each packet and, together with the shared key, taken as input to generate a key string. With the key string and plain-text encryption, the cipher text is generated finally. When a WEP packet is sent, the IV used for packet encryption is also taken as a part of the packet header to be sent. If the IV is generated with an insecure method, for example, repetitive IVs are frequently generated or even the same IV is always generated, the shared key will be exposed easily. If a potential attacker obtains the shared key, it can control network resources and pose a threat to network security.

The IDS prevents this attack by identifying the IV of each WEP packet. When a packet with a weak IV is detected, the IDS immediately determines that this is vulnerability and logs this detected result.

CCMC DoS Attack Detection

The CMCC DoS attack detection refers to that for every STA which is connected or tries to access, if the number of Action, Association, Authentication, Deauthentication, Disassociation, Reassociation, Probe Request or Null data packets is larger than the set threshold, an attack is deemed existing.

2.3.3 User Isolation

Because of the mobility and uncertainty of STAs, STA information privacy appears to be particularly important in some occasions (especially public areas). Therefore, direct STA communication should be restricted. The user isolation technology can avoid insecure access between STAs in WLAN coverage (e.g., via online neighborhood), so as to prevent private information from being stolen by others.

User isolation isolates STAs, and prevents them from accessing each other without affecting their normal network access, guaranteeing service security. The layer-2 user isolation has the following five types:

- AP-based user isolation
- AP-SSID based user isolation
- AC-based user isolation
- AC-SSID based user isolation
- CMCC user isolation

Working Principle

AP-Based User Isolation

Direct communication cannot be conducted between layer-2 STAs associated with the same AP.

AP-SSID based User Isolation

Direct communication cannot be conducted between STAs in the same WLAN who are associated with the same AP.

AC-based User Isolation

Direct communication cannot be conducted between layer-2 STAs who are associated with the same AC but with different APs. This is effective only in centralized forwarding mode.

AC-SSID based User Isolation

Direct communication cannot be conducted between STAs in the same WLAN who are associated with the same AC but with different APs. This is effective only in centralized forwarding mode.

CMCC User Isolation

CMCC user isolation depends on SSID-based isolation functions. It takes effect on the APs in local forwarding mode and on ACs in centralized forwarding mode.

2.3.4 Rogue Detection and Containment

Network devices are usually divided into two types: illegal (Rogue) and legal. Rogue devices have potential vulnerabilities to be attacked or manipulated, which therefore poses a serious threat or hazard to network security. Rogue detection function can monitor abnormal devices in the whole WLAN, helping the network administrator find hidden dangers in networks.

Rogue detection is applicable to multiple Rogue devices in WLAN: APs, clients, wireless bridges, and Ad-hoc devices. Currently, only the detection on Rogue APs and Ad-hoc devices and unknown STAs is supported.

Rogue device containment counters Rogue devices by sending fake deauthentication frames to the addresses of Rogue devices, as so to prevent STAs from accessing illegal service or illegal STAs from accessing the devices.

Working Principle

Rogue Detection

The Rogue detection function is conducted by an AP in Monitor mode or Hybrid mode. WIDS captures wireless packets in the air by deploying some APs in WLAN and setting them to operate in Monitor or Hybrid mode. By conducting analysis and statistics of monitored wireless packets, the AP can obtain information on the Rogue device. Meanwhile, the network administrator can also prepare illegal device detection rules to monitor abnormal devices in the whole WLAN.

Unknown STA Detection

The unknown STA detection function monitors the probe request packets from non-accessed STAs in the network, and the network administrator can also use configuration to specify information on the unknown STA.

Rogue Containment

The Rogue containment refers to a service which uses the means of simulating fake broadcast deauthentication packets to contain Rogue devices that meet the containment mode rules, and to prevent normal STAs from accessing Rogue devices.

Unknown STA Containment

The unknown STA containment refers to denying unknown STA access by directly constructing deauthentication packets.

CMCC Rogue Detection

The function of CMCC Rogue detection is aimed at preventing illegal APs from interfering with legal APs in signal transmission, and even preventing legal STAs from being cheated out of registration information. Based on Rogue detection function, CMCC Rogue detection cuts off the network connection of illegal APs in collaboration with the background system, if conditions permit.

2.4 Configuration

Configuration	Description and Command	
Configuring Frame Filtering	(Optional) It is used to configure frame filtering.	
	kickout threshold	Configures the low-rate kickout threshold.
	whitelist mac-address [**name** *another-name*]	Adds an entry to the whitelist.
	whitelist max	Configures the length of the whitelist.
	static-blacklist mac-address [**name** *another-name*]	Adds an entry to the static blacklist.
	static-blacklist max	Configures the length of the static blacklist.
	dynamic-blacklist enable	Enables the dynamic blacklist function.
	dynamic-blacklist lifetime	Configures the lifetime of the dynamic blacklist.
	dynamic-blacklist ac-max	Configures the length of the dynamic blacklist on ACs.
	dynamic-blacklist ap-max	Configures the length of the dynamic blacklist on APs.
	dynamic-blacklist mac-address [**name** *another-name*]	Adds an entry to the dynamic blacklist.
	ssid-filter max	Configures the SSID-based blacklist and whitelist and their length.
	ssid-filter blacklist mac-address [**name** *another-name*]	Adds an entry to the SSID-based blacklist.
	ssid-filter blacklist max	Configures the length of the SSID-based blacklist, 256 by default.
	ssid-filter whitelist mac-address	Adds an entry to the SSID-based whitelist.
	ssid-filter whitelist max	Configures the length of the SSID-based whitelist, 256 by default.
Configuring IDS	(Mandatory) It is used to configure IDS.	
	attack-detection enable	Specifies the IDS type.
	attack-detection ddos	Configures the interval and packet threshold of DDoS attack detection.

Configuration	Description and Command	
	attack-detection flood multi-mac	Configures the interval and packet threshold of multi-STA flooding attack detection.
	attack-detection flood single-mac	Configures the interval and packet threshold of single-user flood attack detection.
	attack-detection spoof	Configures the interval and packet threshold of the spoofing attack detection.
	attack-detection weak-iv	Configures the interval and packet threshold of the weak IV attack detection.
	attack-detection statistics ac-max	Configures the length of IDS statistics on ACs.
	attack-detection statistics ap-max	Configures the length of IDS statistics on APs.
	dos-detection	Configures CMCC DoS attack detection.
Configuring User Isolation	(Optional) It is used to configure user isolation.	
	user-isolation enable	Enables the AC-based, AP-based, AC-SSID-based, AP-SSID-based and CMCC layer-2 user isolation.
	user-isolation permit-mac	Adds an entry to the permissible MAC list for user isolation.
	user-isolation permit-mac max	Configures the length of the permissible MAC list for user isolation.
Configuring Rogue Detection and Containment	(Optional) It is used to set the device detection and containment function.	
	countermeasures enable	Enables the Rogue containment function.
	countermeasures ap-max	Configures the maximum number of contained devices once.
	countermeasures channel-match	Enables channel-based containment.
	countermeasures interval	Configures the containment interval.
	countermeasures mode	Configures the containment mode.
	countermeasures rssi-min	Configures the minimum containment RSSI.
	countermeasures fuzzy-enable	Enables fuzzy containment.
	device aging duration	Configures the aging duration of the detected devices.
	device attack mac-address	Adds an entry to the static attack list.
	device attack max	Configures the length of the static attack list.
	device black-ssid	Adds an entry to the SSID-based blacklist.
	device max-black-ssid	Configures the length of the SSID-based blacklist.
	device friendly-flags	Configures the device friendly flag.
	device permit mac-address	Adds an entry to the permissible MAC list.
	device permit mac-address max	Configures the length of the permissible MAC list.
	device permit ssid	Adds an entry to the permissible SSID list.
	device permit max-ssid	Configures the length of the permissible SSID list.

Configuration	Description and Command	
	device permit vendor bssid	Adds an entry to the permissible vendor list.
	device permit vendor bssid max	Configures the length of the permissible vendor list.
	device unknown-sta dynamic-enable	Enables unknown STA detection and containment.
	device unknown-sta mac-address	Adds an entry to the unknown STA list
	device unknown-sta mac-address max	Configures the length of the unknown STA list.
	device unknown-sta report enable	Enables unknown STA detection information reporting.
	device channel-bind radio	Configures the scanning channel of a specified radio.
	device scan-para	Configures the CMCC illegal AP detection.
	device detected-ap-max	Configures the maximum number of detected APs.
	hybrid-scan radio	Configures the scanning status of a specified radio.
	scan-channels { 802.11a | 802.11b } channels	Configures the scanning channel of a specified AP.
	scan-channels dual-band	Configures automatic channel scanning between different frequency bands.
	rogue-ap countermeasures enable	Enables CMCC Rogue containment.
configuring AP Working Modes	(Optional) It is used to set the AP working mode.	
	device mode	Configures the AP working mode.

2.4.1 Configuring Frame Filtering

Configuration Effect

- Configure the frame filtering rules to provide packet filtering services.

Notes

- An STA cannot be configured in both the static blacklist and the whitelist.
- An STA cannot exist in both the blacklist and whitelist of the same SSID.

Configuration Steps

Configuring the Low-Rate Filter

- (Optional) The **kickout threshold** command is used in WIDS configuration mode to configure the low-rate kickout threshold. The low-rate filtering function effectively works only after the low-rate kickout threshold is configured (larger than 0).
- Unless otherwise noted, enable this function only on ACs which needs to support the low-rate STA filtering function.

Command	**kickout threshold** *rate*
Parameter Description	*rate*: Indicates the low-rate kickout threshold ranging from 0 to 130 Mbps.
Defaults	By default, low-rate STAs are not filtered out, and the kickout threshold is 0.
Command Mode	WIDS configuration mode
Usage Guide	The STAs can select different low-rate STA filtering thresholds based on requirements.

Configuring the Whitelist

- Optional.
- Unless otherwise noted, enable this function only on ACs which need the whitelist function.
- To configure the whitelist entry, the same as above.
- To configure the whitelist length, the same as above.
- Run the **whitelist mac-address** command to add an entry to the whitelist in WIDS configuration mode. The whitelist filtering function effectively works only after an effective whitelist entry is configured.
- Run the **whitelist max** command to configure the maximum number of entries in the whitelist in WIDS configuration mode.
- One another-name may map to multiple MAC addresses, while one MAC address can map to only one another-name.
- The another-name is null if it is not configured.

Command	**whitelist** { **mac-address** *H.H.H* [**name** *another-name*] |**max** *num* }
Parameter Description	**mac-address** *H.H.H*: Indicates the MAC address of a whitelist entry. **name** *another-name*: Indicates the another-name of the MAC address in the whitelist. **max** *num*: Indicates the length of the whitelist ranging from 1 to 2,048.
Defaults	By default, the whitelist is empty and the whitelist length is 1,024.
Command Mode	WIDS configuration mode
Usage Guide	The whitelist function takes effect only when the whitelist has entries.

Configuring the Static Blacklist

- Optional.
- Unless otherwise noted, enable this function only on ACs which need the static blacklist function.
- To configure the static blacklist entry, the same as above.
- To configure the static blacklist length, the same as above.
- Run the **static-blacklist mac-address** command to add an entry to the static blacklist in WIDS configuration mode. The static blacklist filtering function effectively works only after an effective static blacklist entry is configured.
- Run the **static-blacklist max** command to configure the maximum number of entries in the static list in WIDS configuration mode, indicating the maximum number of permissible static blacklist entries on the device.

- One another-name may map to multiple MAC addresses, while one MAC address can map to only one another-name.
- The another-name is null if it is not configured.

Command	**static-blacklist** { **mac-address** *H.H.H* [**name** *another-name*] | **max** *num* }
Parameter Description	**mac-address** *H.H.H*: Indicates the MAC address of a static blacklist entry. **name** *another-name*: Indicates the another-name of the MAC address in the static blacklist. **max** *num*: Indicates the length of the static blacklist ranging from 1 to 2,048.
Defaults	By default, the static blacklist is empty and the static blacklist length is 1,024.
Command Mode	WIDS configuration mode
Usage Guide	The static blacklist function takes effect only when the static blacklist has entries.

Configuring the Dynamic Blacklist

- Optional.
- Unless otherwise noted, enable this function only on ACs which need the dynamic blacklist function.
- Run the **dynamic-blacklist enable** command to enable the dynamic blacklist function in WIDS configuration mode. A dynamic blacklist entry is generated dynamically along with the IDS attack detection and works only after the dynamic blacklist function is enabled.
- Run the **dynamic-blacklist lifetime** command to configure the service life of the dynamic blacklist in WIDS configuration mode, indicating how long the dynamic blacklist exists in the device.
- Run the **dynamic-blacklist** { **ac-max** | **ap-max** } command to configure the maximum number of dynamic blacklist entries on both ACs and APs in WIDS configuration mode.
- Run the **dynamic-blacklist mac-address** command to add an entry to the dynamic blacklist in WIDS configuration mode.

Command	**dynamic-blacklist** { **enable** | **lifetime** *time* |**ac-max** *num* |**ap-max** *num* | **mac-address** *H.H.H* }
Parameter Description	**enable**: Enables the dynamic blacklist function **lifetime** *time*: Indicates the service life of the dynamic blacklist ranging from 60 to 86,400 seconds. **ac-max** *num*: Indicates the length of the dynamic blacklist on ACs. **ac-max** *num*: Indicates the length of the dynamic blacklist on APs. **mac-address** *H.H.H*: Indicates the MAC address of a dynamic blacklist entry.
Defaults	By default, the dynamic blacklist function is disabled. The default length of the dynamic blacklist is 2,048 on ACs and APs with 300-second lifetime.
Command Mode	WIDS configuration mode
Usage Guide	A dynamic blacklist entry is generated in the IDS attack detection function.

Configuring the SSID-Based Blacklist

- Optional.
- Unless otherwise noted, enable this function only on ACs which need the SSID-based blacklist function.

- To configure the SSID-based blacklist entry, the same as above.
- To configure the SSID-based blacklist length, the same as above.
- To configure the SSID list length, the same as above.
- Run the **ssid-blacklist mac-address** command to add an entry to the SSID-based static blacklist in WIDS configuration mode. The static blacklist filtering function effectively works only after an effective static blacklist entry is configured.
- Run the **ssid-filter blacklist max** command to configure the maximum number of entries in the SSID-based static blacklist in WIDS configuration mode.
- One another-name may map to multiple MAC addresses, while one MAC address can map to only one another-name.
- The another-name is null if it is not configured.

Command	**ssid-filter** { **max** *num* | **blacklist mac-address** *H.H.H* [**name** *another-name*] **in-ssid** *string* | **blacklist max** *num* }
Parameter Description	**max** *num*: Indicates the maximum length of the SSID-based blacklist, ranging from 1 to 128. The default is 64. **blacklist mac-address** *H.H.H* **in-ssid** *string*: Adds an entry to the specified SSID-based blacklist. **name** *another-name*: Indicates the another-name of the MAC address in the specified SSID blacklist. **blacklist max** *num*: Configures the length of the SSID-based blacklist, ranging from 1 to 2048.
Defaults	The SSID-based blacklist is empty.
Command Mode	WIDS configuration mode
Usage Guide	This function takes effect only when the SSID-based blacklist has entries.

Configuring the SSID-Based Whitelist

- Optional.
- Unless otherwise noted, enable this function only on ACs which need the SSID-based whitelist function.
- To configure the SSID-based whitelist entry, the same as above.
- To configure the SSID-based whitelist length, the same as above.
- Run the **ssid-filter whitelist mac-address** command to add an entry to the SSID-based whitelist in WIDS configuration mode. The whitelist filtering function effectively works only after an effective whitelist entry is configured.
- Run the **ssid-filter whitelist max** command to configure the maximum number of entries in the SSID-based whitelist in WIDS configuration mode.
- One another-name may map to multiple MAC addresses, while one MAC address can map to only one another-name.
- The another-name is null if it is not configured.

Command	**ssid-filter** { **whitelist mac-address** *H.H.H* [**name** *another-name*] **in-ssid** *string* | **whitelist max** *num* }
Parameter Description	**whitelist mac-address** *H.H.H* **in-ssid** *string*: Configures the whitelist entry for a specified SSID. **name** *another-name*: Indicates the another-name of the MAC address in the specified SSID whitelist. **whitelist max** *num*: Configures the length of the SSID-based whitelist, ranging from 1 to 2048.

Defaults	The SSID-based whitelist is empty.
Command Mode	WIDS configuration mode
Usage Guide	This function takes effect only when the SSID-based whitelist has entries.

Verification

Conduct related function verifications based on corresponding frame filtering rules.

- Check the low-rate STA filtering function. The packets are discarded and the low-rate STAs are successfully removed.
- Check the whitelist function. When the whitelist is configured, the STAs not included in the whitelist cannot join the AP.
- Check the static blacklist function. When the static blacklist is configured, the STAs included in the static blacklist cannot join the AP.
- Check the dynamic blacklist function. When the dynamic blacklist function is enabled, entries in the dynamic blacklist can be generated along with the IDS attack detection, and STAs in the dynamic blacklist cannot join the AP again.
- Check the SSID-based blacklist function. When the SSID-based blacklist is configured, STAs in the SSID-based blacklist cannot join this SSID service.
- Check the SSID-based whitelist function. When the SSID-based whitelist is configured, STAs not included in the SSID-based whitelist cannot join this SSID service.

Configuration Example

Configuring the Whitelist Entry

Scenario **Figure 2-5**	Configuration Steps	● Add an entry to thewhitelist on the AC.

	Ruijie# configure terminal Ruijie(config)# wids Ruijie(config-wids)# whitelist mac-address 0000.0000.0001
Verification	After the STA configures the whitelist entry, the following methods can be used to check the configuration. ● Run the **show wids whitelist** command to display the information on related parameters configured onthe STA. ● Use the device to verify whether the function has taken effect.
	Ruijie#show wids whitelist ------------------ Whitelist Information ------------------ num Mac-address 1 0000.0000.0001

Common Errors

N/A

2.4.2 Configuring IDS

Configuration Effect

- IDS can be used to timely find and defend against malicious or unintentional attacks in WLAN.

Notes

- IDS needs to be used together with the dynamic blacklist function, to effectively prevent attacks against WLAN.

Configuration Steps

↘ Specifying the IDS Type

- (Optional) IDS is disabled by default.
- Unless otherwise noted, configure this function on ACs which need the IDS attack detection function.
- To configure the IDS attack detection, the same as above.

Command	**attack-detection enable** { **all** | **ddos** | **flood** | **spoof** | **weak-iv** }
Parameter Description	**ddos**: Enables DDoS attack detection. **flood**: Enables flooding attack detection. **spoof**: Enables spoofing attack detection. **weak-iv**: Enables Weak IV attack detection. **all**: Enables all IDS attack detection.
Defaults	All IDS attack detection is disabled by default.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring DDoS Attack Detection

- Optional.
- Unless otherwise noted, configure this function on ACs which need DDoS attack detection.
- To configure the thresholds and intervals of a specified type of packets in DDoS attack detection, the same as above.

Command	**attack-detection ddos** { **arp-threshold** *num*| **icmp-threshold** *num*| **syn-threshold** *num* | **interval** *time* }
Parameter Description	**arp-threshold** *num*: Indicates ARP packet threshold ranging from1 to 10,000 pps. **icmp-threshold** *num*: Indicates ICMP packet threshold ranging from110,000 pps. **syn-threshold** *num*: Indicates SYN packet threshold ranging from1 to 10,000 pps. **interval** *time*: Indicates the period of DDoS attack detection ranging from 10 to 60 seconds.
Defaults	By default, the interval of DDoS attack detection is 30 seconds, and the three DDoS attack detection thresholds are 50 pps for ARP packets, 100 pps for ICMP packets, and 50 pps for SYN packets.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring Flooding Attack Detection

- (Optional) Flooding attack detection is disabled by default.
- Unless otherwise noted, configure this function on ACs which need the flooding attack detection.
- To configure the threshold and interval of a specified types of packets in flooding attack detection, the same as above.
- Run the **attack-detection flood single-mac** { **total** | **assoc** | **reassoc** | **disassoc** | **probe** | **action** | **auth** | **deauth** | **null-data** } **threshold***num***interval***time* command to configure the threshold and interval of a specified type of packets for single-STAflooding attack in WIDS configuration mode.
- Run the **attack-detection flood multi-mac** { **assoc** | **reassoc** | **disassoc** | **probe** | **action** | **auth** | **deauth** | **null-data** } **threshold** *num* **interval** *time* command to configure the threshold and interval of a specified type of packets for multi-STA flooding attack in WIDS configuration mode.

Command	**attack-detection flood single-mac** { **total**	**assoc**	**reassoc**	**disassoc**	**probe**	**action**	**auth**	**deauth |** **null-data** } **threshold** *num* **interval** *time*
Parameter Description	**single-mac**: Indicates single STA detection. **total**: Indicates all packets. **assoc**: Indicates Association packets. **reassoc**: Indicates Reassociation packets. **disassoc**: Indicates Disassociation packets. **probe**: Indicates Probe packets. **action**: Indicates Action packets. **auth**: Indicates Authentication packets. **deauth**: Indicates Deauthentication packets. **null-data**: Indicates Null packets. *num*: Indicates the packet threshold of flooding attack detection ranging from 1 to 10000.

	time: Indicates the interval of flooding attack detection ranging from 10 to 60 seconds.
Defaults	All packet thresholds of flooding attack detection, by default, 300 for single-STA, 4800 for multi-STA, and 10 seconds of the statistic interval
Command Mode	WIDS configuration mode
Usage Guide	N/A

Command	**attack-detection flood multi-mac** { **assoc** | **reassoc** | **disassoc** | **probe** | **action** | **auth** | **deauth** | **null-data** } **threshold** *num* **interval** *time*
Parameter Description	**multi-mac**: Indicates multi-STA detection. **assoc**: Indicates Association packets. **reassoc**: Indicates Reassociation packets. **disassoc**: Indicates Disassociation packets. **probe**: Indicates Probe packets. **action**: Indicates Action packets. **auth**: Indicates Authentication packets. **deauth**: Indicates Deauthentication packets. **null-data**: Indicates Null packets. *num*: Indicates the packet threshold of flooding attack detection ranging from 1 to 10000. *time*: Indicates the interval of flooding attack detection ranging from 10 to 60 seconds.
Defaults	All packet thresholds of flooding attack detection, by default, 300 for single-STA, 4800 for multi-STA, and 10 seconds of the statistic interval
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring Spoofing Attack Detection

- (Optional) Spoofing attack detection is disabled by default.
- Unless otherwise noted, configure this function on ACs which need the spoofing attack detection.
- To configure the threshold and interval of a specified type of packets in spoofing attack detection, the same as above.

Command	**attack-detection spoof** { **threshold** *num* |**interval** *time* }
Parameter Description	**threshold** *num*: Indicates the packet threshold of spoofing attack detection ranging from 1 to 1,000. **interval** *time*: Indicates the interval of spoofing attack detection ranging from 10 to 60 seconds.
Defaults	By default, the packet threshold is 1 and the detection interval is 50 seconds.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring Weak IV Attack Detection

- (Optional) The Weak IV attack detection function is disabled by default.
- Unless otherwise noted, configure this function on ACs which needs the Weak IV attack detection.
- To configure the thresholds and intervals for specified types of packets in Weak IV attack detection, the same as above.

Command	**attack-detection weak-iv** { **threshold** *num*| **interval** *time* }
Parameter Description	**threshold** *num*: Indicates the packet threshold of weak IV attack detection ranging from 1 to 10,000. **interval** *time*: Indicates the interval of weak IV attack detection ranging from 1 to 60 seconds.
Defaults	The default interval of Weak IV detection is 15 seconds, and the default detection threshold is 10.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring CMCC DoS Attack Detection

- (Optional) CMCC DoS attack detection is disabled by default.
- Unless otherwise noted, configure this function on ACs which need the Weak IV attack detection.
- To configure the threshold and interval of a specified type of packets in CMCC DoS attack detection, the same as above.

Command	**dos-detection** { **enable** | **threshold** *num*| **interval** *time* }
Parameter Description	**enable:** Enables CMCC DoS attack detection **threshold** *num*: Indicates the packet threshold of CMCC DoS attack detection ranging from 1 to 5,000. **interval** *time*: Indicates the interval of the CMCC DoS attack detection ranging from 1,000 to 60,000 ms.
Defaults	The interval of CMCC DoS attack detection is 1,000 ms, and the detection threshold is 30.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Verification

Carry out related verifications based on the IDS attack detection type:

- DDoS attack detection, detecting the ARP packet attack, ICMP packet attack and SYN packet attack.
- Flooding attack detection, detecting the multi-STA flooding attack and single-STA flooding attack.
- Spoofing attack detection, detecting the broadcast disassociation and deauthentication packet attacks.
- Weak IV attack detection, detecting the weak IV packet attack.
- CMCC DoS attack detection, detecting the DoS attack.

Configuration Example

Configuring DDoS Attack Detection

Scenario **Figure 2-6**	Configuration Steps	● Specify the IDS type and configure related thresholds on the AC.
	`Ruijie# configure terminal` `Ruijie(config)# wids` `Ruijie(config-wids)# attack-detection enable flood` `Ruijie(config-wids)# attack-detection ddos interval 10`
Verification	● If a DDoS attack exists, related syslog information will be printed on the AC.
	`*Feb 7 13:37:03: %WIDS-6-ATTACK: Client(0025.64b8.2ffa): ARP DDOS attack to Ap (1414.0902.0016).` `Feb 7 13:37:03: %WIDS-6-ATTACK: Client(0025.64b8.2ffa): ICMP DDOS attack to Ap (1414.0902.0016).` `Feb 7 13:37:03: %WIDS-6-ATTACK: Client(0025.64b8.2ffa): SYN DDOS attack to Ap (1414.0902.0016).`

Common Errors

N/A

2.4.3 Configuring User Isolation

Configuration Effect

- After user isolation is configured, direct communication cannot be conducted between STAs meeting the user isolation rules.

Notes

- User isolation is only valid for layer-2STAs.

Configuration Steps

Configuring the User Isolation Mode

- Optional.
- Unless otherwise noted, configure this function on ACs.

Command	**user-isolation** { **ac** | **ap** | **ssid-ac** | **ssid-ap** | **wlan-id** *num* } **enable**
Parameter Description	**ac:** Indicates AC-based layer-2 user isolation. **ap:** Indicates AP-based layer-2 user isolation. **ssid-ac:** Indicates AC-SSID-based layer-2 user isolation. **ssid-ap:** Indicates AP-SSID-based layer-2 user isolation. **wlan-id** *num*: Indicates SSID-based layer-2 user isolation.
Defaults	User isolation is disabled.
Command Mode	WIDS configuration mode
Usage Guide	The AC-based and AC-SSID-based layer-2 user isolation are effective only in centralized forwarding mode.

Configuring the Permissible MAC List for User Isolation

- Optional.
- Unless otherwise noted, configure this information on ACs.
- To configure the isolation list length, the same as above.

Command	**user-isolation permit-mac** {*H.H.H* | **max** *num* }
Parameter Description	*H.H.H*: Indicates the permissible MAC list entry for user isolation. **max** *num*: Indicates the permissible MAC list length for user isolation ranging from 1 to 1,024.
Defaults	The permissible STA's MAC list for isolation is empty, with the default length of 1,024.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Verification

- Carry out related verifications based on the isolation mode.

Configuration Example

Configuring User Isolation

Scenario	

Figure 2-7	Configuration Steps	● Configure the AP-based layer-2 user isolation on the AC.
	`Ruijie# configure terminal` `Ruijie(config)# wids` `Ruijie(config-wids)# user-isolation ap enable`
Verification	● Run the **show running-config** command to display the information on related parameters configured by the STA.
	`Ruijie#show running-config` `…` `!` `wids` ` user-isolation ap enable` `!`

Common Errors

N/A

2.4.4 Configuring Rogue Detection and Containment

Configuration Effect

Configure Rogue detection and containment provide illegal device suppression and maintain WLAN security.

Notes

The detection and containment of Rogue devices takes effect only when the AP working mode is Hybrid or Monitor.

Configuration Steps

Enabling Rogue Containment

- Optional. Run the **countermeasures enable** command to enable Rogue containment in WIDS configuration mode.
- Unless otherwise noted, this function is configured on ACs which need the Rogue containment function.

Command	**countermeasures enable**
Parameter Description	N/A
Defaults	Rogue containment is disabled.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Configuring the Containment Interval

- Optional. Run the **countermeasures interval** *time* command to configure the interval of Rogue containment in WIDS configuration mode.
- Unless otherwise noted, configure the containment interval on ACs which need the Rogue device containment period.

Command	**countermeasures interval** *time*
Parameter Description	time: Indicates the containment interval ranging from 100 to 10,000 ms.
Defaults	The default containment interval is 1,000 ms.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Configuring the Containment Mode

- Optional. Run the **countermeasures mode** { **all** | **adhoc** | **config** | **rogue** | **ssid** } command to configure the Rogue containment mode in WIDS configuration mode.
- Unless otherwise noted, configure this on ACs which need Rogue containment mode.

Command	**countermeasures mode** { **all**	**adhoc**	**config**	**rogue**	**ssid** }
Parameter Description	**adhoc**: Indicates Ad-hoc containment mode, countering Ad-hoc devices. **config**: Indicates Config containment mode, countering devices which meet entries in the SSID blacklist and static attack list. **rogue**: Indicates Rogue containment mode, countering devices whose RSSI is larger than the threshold. **ssid**: Indicates SSID containment mode, countering devices with the same SSID but not on the same AC. **all**: Indicates all the above containment modes.

Defaults	No containment mode is specified by default.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Configuring the Static Attack List

- Optional. Run the **device attack mac-address** *H.H.H* command to configure the static attack statistic list information in WIDS configuration mode.
- Unless otherwise noted, configure this on ACs which need the static attack list.

Command	**device attack** { **mac-address** *H.H.H* |**max** *num* }
Parameter Description	**mac-address** *H.H.H*: Indicates the MAC address of a static attack list entry. **max** *num*: Indicates the length of the static attack list, ranging from 1 to 1,024.
Defaults	The static attack list is empty, and the length of the static attack list is 512 by default.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Configuring the SSID-based Blacklist

- Optional. Run the **device black-ssid** *ssid* command to configure the SSID blacklist information in WIDS configuration mode.
- Unless otherwise noted, configure this on ACs which need the SSID blacklist.

Command	**device { black-ssid** *ssid* |**max-black-ssid** *num* }
Parameter Description	**black-ssid** ssid: Indicates the SSID blacklist entry. **max-black-ssid** *num*: Indicates the SSID blacklist length, ranging from 1 to 1,024.
Defaults	The SSID blacklist is empty, and the SSID blacklist length is 512 by default.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Configuring the Lists of Permissible MACs, SSIDs and Vendors

- Optional.
- Unless otherwise noted, configure these on ACs which need the permissible MAC, permissible SSID and permissible vendor lists.
- Run the **device permit mac-address** *H.H.H* command to configure the permissible MAC list entry in WIDS configuration mode.
- Run the **device permit ssid** *H.H.H* command to configure the permissible SSID list entry in WIDS configuration mode.
- Run the **device permit vendor** *H.H.H* command to configure the permissible vendor list entry in WIDS configuration mode.

Command	**device permit** { **mac-address** *H.H.H* | **mac-address max** *num* | **ssid** *ssid* | **max-ssid** *num* | **vendor bssid** *H.H.H* | **vendor bssid max** *num* }
Parameter Description	**mac-address** *H.H.H*: Indicates the permissible MAC list entry, null by default. **mac-address max** *num*: Indicates the permissible MAC list length, ranging from 1 to 2,048, 1,024 by default. **ssid** *ssid*: Indicates the permissible SSID list entry, null by default. **max-ssid** *num*: Indicates the permissible SSID list length, ranging from 1 to 1,024, 512 by default. **vendor bssid** *H.H.H*: Indicates the permissible vendor list entry, null by default. **vendor bssid max** *num*: Indicates the permissible vendor list length, ranging from 1 to 1,024, 512 by default.
Defaults	See the **Parameter Description**.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Configuring the Maximum Number of Contained Devices Once

- Optional. Run the **countermeasures ap-max** *ap-num* command to configure the quantity of one-time Rogue device containment in WIDS configuration mode.
- Unless otherwise noted, configure this on ACs which need to configure the contained Rogue device quantity.

Command	**countermeasures ap-max** *ap-num*
Parameter Description	*ap-num*: Indicates the maximum number of countered devices each time, ranging from 1 to 256.
Defaults	The default maximum number of countered devices is 30.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Configuring the Aging Duration of the Detected Devices

- Optional. Run the **device aging duration** *time* command to configure the aging duration of the detected devices in WIDS configuration mode.
- Unless otherwise noted, configure this on ACs which need the aging time.

Command	**device aging duration** *time*
Parameter Description	*time*: Indicates the aging duration, ranging from 500 to 5,000 seconds.
Defaults	The default aging duration is 1,200 seconds.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Configuring the Device Friendly Flag

- Optional. Run the **device friendly-flags** *value* command to configure the device friendly flag in WIDS configuration mode. With the device friendly flag, the AP device can identify devices on the same AC.
- Unless otherwise noted, configure this on ACs which need the device friendly flag.

Command	**device friendly-flags***value*
Parameter Description	*value*: Indicates the device friendly flag, ranging from 1 to 4294967295.
Defaults	The default value is 0.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Configuring the Minimum Containment RSSI

- Optional. Run the **countermeasures rssi-min** *num* command to configure the minimum containment RSSI in WIDS configuration mode. A Rogue device which exceeds this RSSI will be countered.
- Unless otherwise noted, configure this on ACs which need logs to be written into the memory buffer.

Command	**countermeasures rssi-min** *num*
Parameter Description	*num*: Indicates the minimum containment RSSI, ranging from 0 to 75 (-95 to -20).
Defaults	The default minimum containment RSSI is 25 (-70) by default.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Enabling Channel-Based Containment

- Optional. Run the **countermeasures channel-match** command to enable channel-based containment function in WIDS configuration mode. The channel-based containment can be conducted based on the channel on which the detected Rough device operates.
- Unless otherwise noted, configure this on ACs which need the channel-based containment function.

Command	**countermeasures channel-match**
Parameter Description	**channel-match**: Enables channel-based containment.
Defaults	Channel-based containment is disabled.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Configuring Fuzzy Containment

- Optional. Run the **countermeasures fuzzy-enable** command to configure the fuzzy containment function in WIDS configuration mode. Fuzzy match is performed based on the SSID of the rogue AP. For example, if the SSID of the local

host is RUIJIE-WEB, the rogue AP whose SSID is RU1JIE-WEB can be contained after the fuzzy containment function is enabled.

- Unless otherwise specified, configure the fuzzy containment function on ACs which require this function.

Command	**countermeasures fuzzy-enable**
Parameter Description	N/A
Defaults	The fuzzy containment function is disabled by default.
Command Mode	WIDS configuration mode
Usage Guide	If containment modes include the configuration containment mode, rogue APs whose SSID are similar to those in the SSID blacklist are contained. If containment modes include the SSID containment mode, rogue APs whose SSIDs are similar to the SSID of the local host are contained. Fuzzy containment takes effect only in configuration containment mode and SSID containment mode.

Enabling Unknown STA Detection and Containment

- Optional.
- Unless otherwise noted, configure this on ACs which need the unknown STA detection and containment function.
- Run the **device unknown-sta dynamic-enable** command to enable the unknown STA detection and containment function in WIDS configuration mode.
- Run the **device unknown-sta mac-address** *H.H.H* command to configure the unknown STA list entry in WIDS configuration mode.

Command	**device unknown-sta** { **dynamic-enable** | **mac-address** *H.H.H* | **mac-address max** *num* }
Parameter Description	**dynamic-enable**: Enables unknown STA detection and containment. **mac-address** *H.H.H*: Configures the unknown STA list entry, empty by default. **mac-address max** *num*: Configures the unknown STA list length, ranging from 1 to 256.
Defaults	Unknown STA detection and containment is disabled.
Command Mode	WIDS configuration mode
Usage Guide	The containment function has no effect when the AP operates in Normal mode.

Enabling Unknown STA Detection Information Reporting

- Optional.
- This command is used to report detected unknown STAs to the AC.
- Run the **device unknown-sta report enable** command to enable the unknown STA detection information reporting function in WIDS configuration mode.

Command	**device unknown-sta report enable**
Parameter Description	N/A

Defaults	The unknown STA detection information reporting function is disabled by default.
Command Mode	WIDS configuration mode
Usage Guide	This function takes effect only when the AP does not operate in Normal mode. The scanning result can be reported to the AC.

Configuring CMCC Rogue Detection

- Optional.
- Unless otherwise noted, configure these on ACs which need the function of CMCC Rogue detection.
- Run the **device channel-bind radio** *radio-id* { **channel** *num*| **max-cycles** *value* } command to configure the scanning channel of a specified radio for CMCC Rogue detection in AP configuration mode.
- Run the **device scan-para** { **radio** *radio-id* **scan-type** { **active** | **passive** } **device-detect** { **enable** | **disable** } | **ap-mode** { **normal** | **monitor** } | **detect-rpt-time** *time* } command to configure the scanning parameters for detection of interoperability with illegal APs in AP configuration mode.
- Run the **rogue-ap countermeasures enable** command to configure the function of containing interoperability with illegal APs in WIDS configuration mode.
- Configure the scanning channel information on interoperability with illegal APs

Command	**device channel-bind radio** *radio-id*{ **channel** *num* | **max-cycles** *value* }
Parameter Description	*radio-id*: Indicates Radio ID of a specified AP. **channel** *num*: Channel value, Chinese channel by default. **max-cycles** *value*: indicates the number of scanning times, 10 by default and ranging from 0 to 255.
Defaults	For details, see the **Parameter Description**.
Command Mode	AP configuration mode
Usage Guide	N/A

Command	**device scan-para** { **radio** *radio-id* **scan-type** { **active** | **passive** } **device-detect** { **enable** | **disable** } **|** **ap-mode** { **normal** | **monitor** } | **detect-rpt-time** *time* }
Parameter Description	**radio** *radio-id*: Radio ID **scan-type active**: Indicates active scanning. The default scanning is passive scanning. **scan-type passive**: Indicates passive scanning. **device-detect enable**: Enables the detection. The detection is disabled by default. **device-detect disable**: Disables the detection. **ap-mode normal**: Indicates The AP works in Normal mode. **ap-mode monitor**: Indicates The AP works in Monitor mode. **detect-rpt-time** time: Indicates the detection reporting period, 60 seconds by default, ranging from 60 to 120 seconds.
Defaults	For defaults, see the **Parameter Description**.

Command Mode	AP configuration mode
Usage Guide	N/A

Command	**rogue-ap countermeasures enable**
Parameter Description	N/A
Defaults	Disabled.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring the Maximum Number of Detected APs

- Optional. Run the **device detected-ap-max** *num* command to configure the maximum number of detected APs in WIDS configuration mode. A smaller configuration value leads to less data being detected on the AP. If less data is detected, the device containment function may not show an obvious containment effect. A larger configuration value requires more memory.
- Unless otherwise noted, configure this on ACs which need the maximum number of detected APs.

Command	**device detected-ap-max** *num*
Parameter Description	*num*: Indicates the maximum number of detected APs, ranging from 1 to 4,096.
Defaults	The default maximum number is 2,048.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring the Scanning Status of a Specified Radio

- Optional. Run the **hybrid-scan radio** *num* **{ disable | enable }** command to configure the scanning status of a specified radio in AP configuration mode. If disabling the configuration leads to AP working in non-normal mode, there will be no device detection data.
- Unless otherwise noted, configure this on ACs which need the radio scanning status.

Command	**hybrid-scan radio** *num* **{ enable	disable }**
Parameter Description	*num*: Indicates a radio ID.
Defaults	All radio scanning is enabled by default.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring the Scanning Channel of a Specified AP

- Optional. Run the **scan-channels { 802.11a | 802.11b } channels** *num1 num2…num13* command to configure the scanning channel in AP configuration mode. If the scanning channel is not configured, there will be no device detection data when the AP operates not in Normal mode.
- Unless otherwise noted, configure this on ACs which need the specified AP scanning channel.

Command	**scan-channels { 802.11a | 802.11b } channels** *num1 num2…num13*
Parameter Description	*num*: Indicates a channel number.
Defaults	The scanning channel is null.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring Automatic Channel Scanning Between Different Frequency Bands

- Optional. Run the **scan-channels dual-band radio** *radio-id* command to perform automatic channel scanning between two frequency bands, to obtain the scanning result of the two frequency bands and perform containment.

Command	**scan-channels dual-band radio** *radio-id*
Parameter Description	*radio-id*: Indicates the radio ID of the AP for which automatic channel scanning between different frequency bands is enabled.
Defaults	Automatic channel scanning between different frequency bands is disabled by default.
Command Mode	AP configuration mode
Usage Guide	The RF modules of partial APs support both the 2.4 GHz and 5 GHz frequency bands. When the RF modules are used for channel scanning, this command can be used for automatic channel scanning between the two frequency bands, to obtain the scanning results of these two frequency bands and perform containment. After the frequency bands are switched, channels configured by running the **scan-channels { 802.11a | 802.11b } channels** command are scanned. In addition, for some APs that have channel restrictions, the restricted channels will be automatically skipped during channel scanning.

Verification

- Run the **show wids detected** command to display the detected results.

Configuration Example

Configuring Rogue Containment

Scenario	

Figure 2-8	Configuration Steps	● Configure Rogue containment information on the AC. Before configuring containment, confirm that the WLAN service has been deployed on the contained AP; otherwise, the containment will not take effect.
	`Ruijie# configure terminal` `Ruijie(config)# wids` `Ruijie(config-wids)# countermeasures enable` `Ruijie(config-wids)# countermeasures mode ssid`
Verification	● Run the **show running-config** command to display the information on related parameters configured by the STA and the log information generated by the system recently.

2.4.5 Configuring AP Working Mode

Configuration Effect

- Based on the configured working mode, the AP can provide different services.

Notes

N/A

Configuration Steps

Configuring AP Working Modes

- Optional.
- Unless otherwise noted, configure this on each AP.

Command	**device mode** { **hybrid** | **monitor** | **normal** } [**radio** *radio-id*]
Parameter Description	**hybrid**: Indicates Hybrid mode, in which the device provides both monitoring service and access service. **monitor:** Indicates Monitor mode, in which the device provides only the monitoring service. **normal**: Indicates Normal mode, in which the device provides only the access service. **radio**: Specifies a radio to provide the monitoring service, while other radios to provide the access service.
Defaults	The working mode of the AP is Normal.
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Run the **show ap-config running** *ap-name* command to display the current working mode of the AP.

Configuration Example

Configuring the AP Working Mode

Scenario **Figure 2-9**	Configuration Steps	● Configure the working mode of a specified AP on the AC.
	Ruijie# configure terminal Ruijie(config)# ap-config ap220 Ruijie (config-ap)#device mode hybrid

3 Configuring CPU Protect Policy

3.1 Overview

CPU Protect Policy (CPP) is a CPU protection policy.

Malicious attacks are often found in network environment. Network devices are occupied with counterfeited management and protocol packets and have no time to process real management and protocol packets. In this way, the attacks bring destructive impacts on device security and network stability. The CPP function protects CPU resources and important packets by means of packet identification and rate limiting.

Protocols and Standards

N/A

3.2 Applications

Application	Description
Rate Limiting	Limits the rate of specified packets.

3.2.1 Rate Limiting

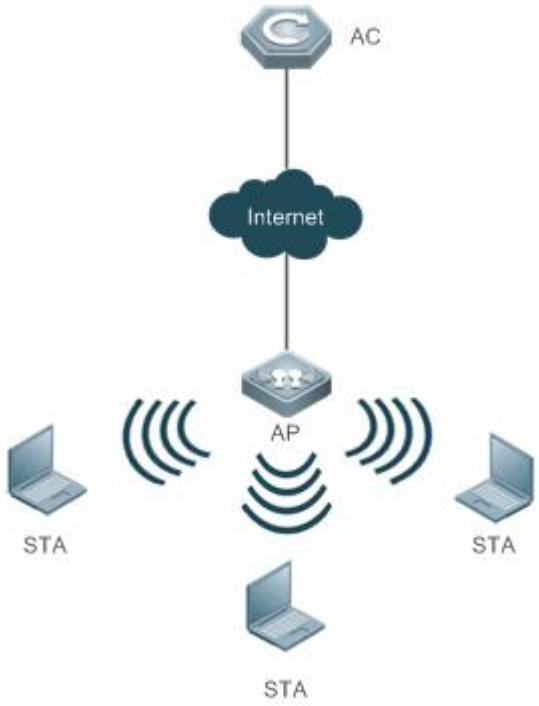
Scenario

The AC and AP are designed with the functions of packet identification and rate limiting, thus protecting the processors.

Figure 3-1 shows the networking topology of the CPP.

1. An AP accesses the AC.
2. Multiple STAs access the AP.
3. Specified packet attacks (see Configuration for details) may occur on STAs in a network. The AC and AP must be able to protect their CPU.

Figure 3-1 Networking Topology

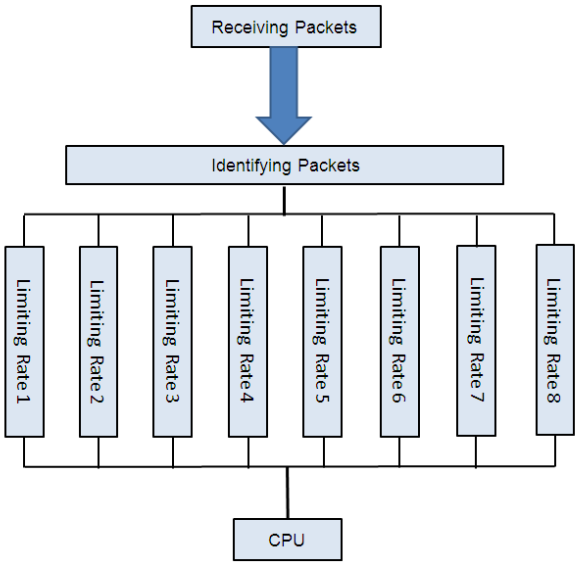


Deployment

- Apply the CPP function on the AC to limit the rate of specified packets.
- Apply the CPP function on the AP to limit the rate of specified packets.

3.3 Features

Figure 3-2 Working Principle



Basic Concepts

Identifying Packets

All packets that are sent to the AC/AP for protocol processing must be classified (e.g., into ARP, BPDU and d1x) through packet identification (for the data classification of different products, see Configuration).

Limiting Rate

An administrator can configure the rate limit for packets of each type, thus effectively dampening high-rate attack packets on the network.

Overview

Feature	Description
Identifying Packets	All packets that are sent to CPU are classified through packet identification.
Limiting Rate	High-rate attack packets are dampened by rate limiting.

3.3.1 Identifying Packets

All packets that are sent to CPU are classified through packet identification.

Working Principle

Identifying Packets

CPP classifies packets and automatically applies the packet identification function by default.

3.3.2 Limiting Rate

An administrator can configure the rate limit for packets of each type, thus effectively dampening high-rate attack packets on the network.

Working Principle

Limiting Rate

Packets that have been identified and classified are rate-limited, and packets that exceed the rate limit are discarded.

3.4 Configuration

Configuration	Description and Command	
Configuring the Rate Limit for Specified Packets	(Optional) It is used to set the rate limit for specified packets.	
	cpu-protect type	Sets the rate limit for specified packets
Configuring the Rate Limit for Wireless Management Packets	(Optional) It is used to set the rate limit for wireless management packets.	
	mgmt-ratelimit disable	Enables/disables the wireless management packet rate limiting function
	mgmt-ratelimit per-cti pps *value*	Configures the CTI-based rate limit for wireless management packets
	mgmt-ratelimit total pps *value*	Configures the AC-based rate limit for wireless management packets

3.4.1 Configuring the Rate Limit for Specified Packets

Configuration Effect

- Configure the rate limit for various types of packets.

Notes

N/A

Configuration Steps

Configuring the Rate limit for Specified Packets

- Optional.
- Enable the CPP function on all ACs/APs unless otherwise specified.
- A user can adjust the default rate limit for packets of each type according to actual requirements.

Command	**cpu-protect type** { **arp** | **bpdu** | **capwap-disc** | **d1x** | **dhcp-option82** | **dhcp-relay-client** | **dhcp-realy-server** | **dhcps** | **igmp** | **ipmc** | **ipv6-nans** | **isis** | **lldp** | **ospf** | **ospfv3** | **pim** | **pppoe** | **rip** | **ripng**

	| **tcp80 | tcp443** | **vrrp** } **pps** *value*
Parameter Description	**arp**: Specifies the ARP packet. **bpdu**: Specifies the IEEE BPDU packet. **capwap-disc**: Specifies the CAPWAP DISCOVER packet. **d1x**: Specifies the 802.1x EAPOL packet. **dhcp-option82**: Specifies the DHCP OPTION82 packet. **dhcp-relay-client**: Specifies the DHCP RELAY CLIENT packet. **dhcp-relay-server**: Specifies the DHCP RELAY SERVER packet. **dhcps**: Specifies the DHCP SNOOPING packet. **igmp**: Specifies the IGMP packet. **ipmc**: Specifies the IPv4 multicast packet. **ipv6-nans**: Specifies the IPv6 neighbor discovery packet. **isis**: Specifies the ISIS packet. **lldp**: Specifies the LLDP packet. **ospf**: Specifies the OSPF packet. **ospfv3**: Specifies the OSPF version3 packet. **pppoe**: Specifies the PPPOE packet. **pim**: Specifies the PIM packet. **rip**: Specifies the IPv4 RIP packet. **ripng**: Specifies the IPv6 RIP packet. **tcp80**: Specifies the Web authentication redirection packet. **Tcp443**: Specifies the HTTPS packet. **vrrp**: Specifies the VRRP packet. **pps** *value*: Specifies the upper limit of packets per second, ranging from 0 to 148,810pps.
Defaults	The default values vary with the product model.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show cpu-protect summary** command to display the configuration.

Configuration Example

Configuring Rate Limit for ARP Packets to 200pps

Scenario Figure 3-3	Configuration Steps	● Configure the rate limit for ARP packets on the AC.
AC	Ruijie#configure terminal Ruijie(config)#cpu-protect type arp pps 200
Verification	After a user configures the rate limit for ARP packets on the AC, the system limits the rate for ARP packets arriving at the CPU based on the new rate limit. ● Run the **show cpu-protect summary** command to check the parameters set by the user. ● Run the **show cpu-protect type arp** command to display statistics about the received ARP packets.
AC	Ruijie#show cpu-protect summary Type Pps ------------------ --------- arp 1000 d1x 128 bpdu 128 lldp 128 dhcp-relay-server 128 dhcp-relay-client 128 dhcps 128 dhcp-option82 128 capwap-disc 128 ipv6-nans 128

arp                   1000      128089    0
```

Common Errors

N/A

3.4.2 Configuring the Rate Limit for Wireless Management Packets

Configuration Effect

- Configure the rate limit for wireless management packets.

Notes

N/A

Configuration Steps

↘ Configuring the Rate Limit for Wireless Management Packets

- Optional. This function is supported only on the AC. By default, the CTI-based rate limit is 8pps. Different ACs adopt different default AC-based rate limits.
- Enable the rate limiting function for wireless management packets on all ACs unless otherwise specified.
- Users can adjust the default rate limit based on CTI or the AC according to actual situations.

Command	**mgmt-ratelimit** { **disable** | **per-cti pps** *value* | **total pps** *value* }
Parameter Description	**disable**: Disables rate limiting function for wireless management packets. It is enabled by default. **per-cti pps** *value*: Configures the CTI-based rate limit, ranging from 1 to 10000pps. The default value is 8pps. **total pps** *value*: Configures the AC-based rate limit , ranging from 1 to 10000pps. Default values vary with

	different ACs.
Defaults	The rate limiting function is enabled by default. The default CTI-based rate limit is 8pps. The default AP-based rate limit varies with different ACs.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running-config** command to display the rate limit of wireless management packets.

Configuration Example

Configuring the AC-based Rate Limit for Wireless Management Packets to 100pps

Scenario Figure 3-4	Configuration Steps	● Configure the AC-based rate limit for wireless management packets.
AC	`Ruijie#configure terminal` `Ruijie(config)#mgmt-ratelimit total pps 200`
Verification	After a user configures the AC-based rate limit the system filters wireless management packets based on the new rate limit. ● Run the **show running-config** command to display the rate limit of wireless management packets.

	● Run the **show mgmt-ratelimit summary** command to display statistics about ARP packets.
AC	Ruijie#show running-config … mgmt-ratelimit total pps 200 … Ruijie#config terminal Ruijie(config)#sh mgmt-ratelimit summary pps max tpkts drop -------- -------- -------------------- -------------------- 0 40 1 0

4 Configuring NFPP

4.1 Overview

The Network Foundation Protection Policy (NFPP) provides guard for switches.

Some malicious attacks are always found in the network environment. These attacks bring heavy burdens to switches, resulting in high CPU usage and abnormal running on switches. These attacks are as follows:

Denial of service (DoS) attacks may greatly consume the memory, entries, or other resources of a switch to cause system service unavailable.

Massive packet traffic is directed to the CPU, occupying the entire bandwidth of packets sent to the CPU. In this case, normal protocol traffic and management traffic cannot be processed by the CPU, causing protocol flapping or management failure. The forwarding on the data plane will also be affected and the entire network will become abnormal.

A great number of packets directed to the CPU consume massive CPU resources, making the CPU highly loaded and thereby causing device management failure or causing abnormal running.

NFPP can effectively protect the system from these attacks. Under attacks, NFPP protects proper running of various system services and keeps a low CPU load, thereby ensuring stable running of the entire network.

4.2 Applications

Application	Description
Attack Detection and Rate Limiting	Due to various malicious attacks such as ARP attacks and IP scanning attacks in the network, the CPU cannot process normal protocol and management traffic, causing protocol flapping or management failure. The NFPP attack detection and rate limiting function is used to limit the rate of attack traffic or isolate attack traffic so that the network can be recovered.
Centralized Rate Limiting and Distribution	Since normal service traffic is too large, you need to classify and prioritize the traffic. When a large number of packets are directed to the CPU, the CPU will be highly loaded, thereby causing device management or device running failure. The centralized rate limiting and distribution function is used to increase the priority of such traffic so that switches can run stably.

4.2.1 Attack Detection and Rate Limiting

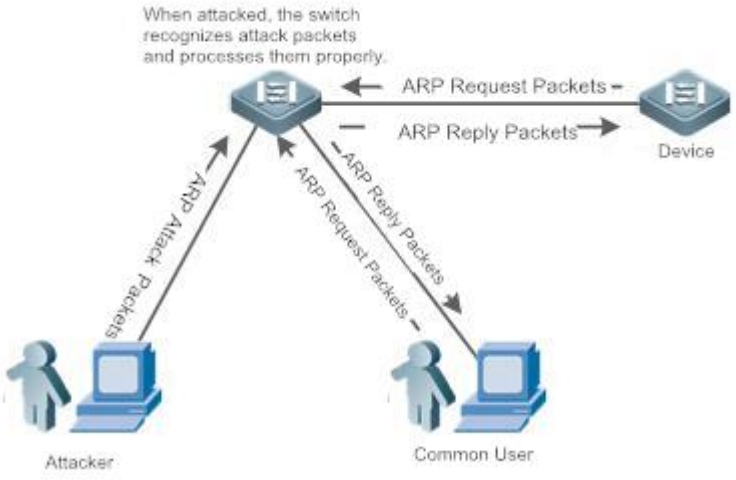
Scenario

NFPP supports attack detection and rate limiting for various types of packets, including Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Dynamic Host Configuration Protocol (DHCP) packets. It also allows users to define packet matching characteristics and corresponding attack detection and rate limiting policies. The attack detection and

rate limiting function takes effect based on each type of packets. This section uses ARP packets as an example to describe the scenario.

If an attacker sends ARP attack packets while the CPU capability is insufficient, a large number of CPU resources will be consumed for processing these ARP packets. If the attacker's ARP packet rate exceeds the maximum ARP bandwidth specified in the CPU Protect Policy (CPP) of the switch, packet loss occurs among normal ARP packets. As shown in Figure 4-1, common users will fail to access the network, and the switch will fail to send ARP responses to other devices.

Figure 4-1



Deployment

- By default, the ARP attack detection and rate limiting function is enabled, with corresponding policies configured. If an attacker's ARP packet rate exceeds the rate limit, the packets will be discarded. If the packet rate exceeds the attack threshold, a monitored host will be generated and prompt information will be output.
- If an attacker's ARP packet rate exceeds the rate limit defined in the CPP and affects normal ARP responses, you can enable attack isolation to discard ARP attack packets based on an ACL and recover the network.

For description of CPP configurations, refer to the "CPP" section.

To maximize the use of NFPP guard functions, modify the rate limits for various services in the CPP based on the application environment or use the configurations recommended by the system. You can run the **show cpu-protect summary** command to display the configurations.

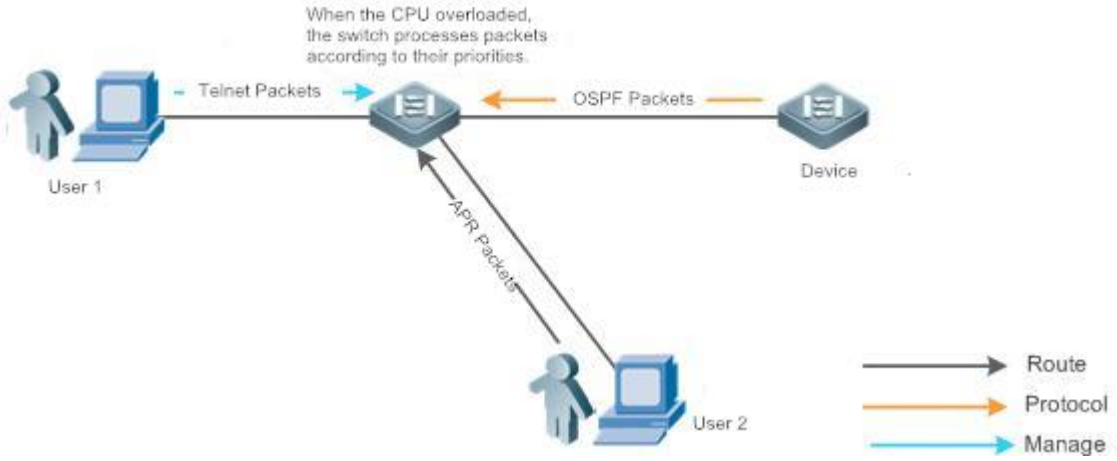
4.2.2 Centralized Rate Limiting and Distribution

Scenario

A switch classifies services defined in the CPP into three types: Manage, Route, and Protocol. Each type of services has an independent bandwidth. Different types of services cannot share their bandwidths. Traffic exceeding the bandwidth threshold is discarded. By such service classification, service packets of a certain type can be processed first.

As shown in Figure 4-2, the switch receives a large number of Telnet packets, OSPF packets, and ARP packets, causing CPU overload. In this case, the CPU cannot process all packets, and a large number of packets are backlogged in the queue, causing various problems such as occasional Telnet disconnection, OSPF protocol flapping, and ARP access failure to hosts.

Figure 4-2



Deployment

- By default, CPU centralized protection is enabled to assign an independent bandwidth and bandwidth ratio to each type of services. At the time, the CPU first processes Telnet packets to ensure uninterrupted connection of the Telnet service, and then processes OSPF packets to maintain OSPF protocol stability, and finally processes ARP packets.
- If the preceding problems occur in default configurations, you can accordingly adjust the bandwidth and bandwidth ratio for various types of services.

4.3 Features

Basic Concepts

↘ ARP Guard

In local area networks (LANs), IP addresses are converted to MAC addresses through ARP, which is significant for safeguarding network security. A large number of illegal ARP packets are sent to the gateway through the network, causing failure of the gateway to provide services for normal hosts. Such packets are called ARP-based DoS attacks. To prevent such attacks, limit the rate of ARP packets and detect and isolate the attack source.

↘ IP Anti-scanning

Many hacker attacks and network virus intrusions start from scanning active hosts in the network. Therefore, many scanning packets rapidly occupy the network bandwidth, causing network communication failure.

To solve this problem, Layer-3 switches provide IP guard to prevent scanning by hackers and Blaster Worm viruses and reduce the CPU load. Currently, there are mainly two types of IP attacks:

- Scanning destination IP address changes: As the greatest threat to the network, this type of attacks not only consumes network bandwidth and increases device load but also is a prelude of most hacker attacks.
- Sending IP packets to non-existing destination IP addresses at high rates: This type of attacks is mainly designed for consuming the CPU load. For a Layer-3 device, if the destination IP address exists, packets are directly forwarded by the switching chip without occupying CPU resources. If the destination IP address does not exist, IP packets are sent to the CPU, which then sends ARP requests to query the MAC address corresponding to the destination IP address. If too many packets are sent to the CPU, CPU resources will be consumed. This type of attacks is less destructive than the former ones.

To prevent the latter type of attacks, limit the rate of IP packets and detect and isolate the attack source.

ICMP Guard

ICMP is a common approach for diagnosing network failures. After receiving an ICMP echo request from a host, the router or switch returns an ICMP echo reply. The preceding process requires the CPU to process the packets, thereby definitely consuming part of CPU resources. If an attacker sends a large number of ICMP echo requests to the destination device, massive CPU resources will be consumed on the device, and the device may even fail to work properly. This type of attacks is called ICMP flood. To prevent this type of attacks, limit the rate of ICMP packets and detect and isolate the attack source.

DHCP Guard

DHCP is widely used in LANs to dynamically assign IP addresses. It is significant for network security. Currently, the most common DHCP attacks, also called DHCP exhaustion attacks, use faked MAC addresses to broadcast DHCP requests. Various attack tools on the live network can easily complete this type of attacks. A network attacker can send sufficient DHCP requests to use up the address space provided by the DHCP server within a period. In this case, authorized hosts will fail to request DHCP IP addresses and thereby fail to access the network. To prevent this type of attacks, limit the rate of DHCP packets and detect and isolate the attack source.

DHCPv6 Guard

DHCP version 6 (DHCPv6) is widely used in LANs to dynamically assign IPv6 addresses. Both DHCP version 4 (DHCPv4) and DHCPv6 have security problems. Attacks to DHCPv4 also apply to DHCPv6. A network attacker can send a large number of DHCPv6 requests to use up the address space provided by the DHCPv6 server within a period. In this case, authorized hosts will fail to request IPv6 addresses and therefore fail to access the network. To prevent this type of attacks, limit the rate of DHCPv6 packets and detect and isolate the attack source.

ND Guard

Neighbor Discovery (ND) is mainly used in IPv6 networks to perform address resolution, router discovery, prefix discovery, and redirection. ND uses five types of packets: Neighbor Solicitation (NS), Neighbor Advertisement (NA), Router Solicitation (RS), Router Advertisement (RA), and Redirect. These packets are called ND packets.

ND snooping monitors ND packets in the network to filter unauthorized ND packets. It also monitors IPv6 hosts in the network and binds the monitored IPv6 hosts to ports to prevent IPv6 address stealing. ND snooping requires ND packets to

be sent to the CPU. If ND packets are sent at a very high rate, the CPU will be attacked. Therefore, ND guard must be provided to limit the rate of ND packets.

Overview

Feature	Description
Host-based Rate Limiting and Attack Identification	Limit the rate according to the host-based rate limit and identify host attacks in the network.
Port-based Rate Limiting and Attack Identification	Limit the rate according to the port-based rate limit and identify port attacks.
Configuring the Monitoring Period	Monitor host attackers in a specified period.
Configuring the Isolation Period	Isolate host attackers or port attackers in a specified period.
Configuring Trusted Hosts	Trust a host by not monitoring it.
Centralized Rate Limiting and Distribution	Classify and prioritize packets.

4.3.1 Host-based Rate Limiting and Attack Identification

Limit the rate of attack packets of hosts and identify the attacks.

Identify ARP scanning.

Identify IP scanning.

Working Principle

Hosts can be identified in two ways: based on the source IP address, VLAN ID, and port and based on the link-layer source MAC address, VLAN ID, and port. Each host has a rate limit and an attack threshold (also called alarm threshold). The rate limit must be lower than the attack threshold. If the attack packet rate exceeds the rate limit of a host, the host discards the packets beyond the rate limit. If the attack packet rate exceeds the attack threshold of a host, the host identifies host attacks, records them in logs, and sends Trap packets.

ARP scanning attacks may have occurred if ARP packets beyond the scanning threshold received in the configured period meet either of the following conditions:

- The link-layer source MAC address is fixed but the source IP address changes.
- The link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes.

Among IP packets beyond the scanning threshold received in the configured period, if the source IP address remains the same while the destination IP address continuously changes, IP scanning attack may have occurred.

When NFPP detects a specific type of attack packets under a service, it sends an alarm to the administrator. If the attack traffic persists, NFPP will not resend the alarm within 60 seconds after generating an alarm.

To prevent CPU resource consumption caused by frequent log printing, NFPP writes attack detection logs to the buffer, obtains them from the buffer at a specified rate, and prints them. NFPP does not limit the rate of Trap packets.

At present, only ARP guard and IP anti-scanning support anti-scanning.

4.3.2 Port-based Rate Limiting and Attack Identification

Limit the rate of port-based attack packets and identify the attacks.

Working Principle

Each port has a rate limit and an attack threshold. The rate limit must be lower than the attack threshold. If the packet rate exceeds the rate limit on a port, the port discards the packets. If the packet rate exceeds the attack threshold on a port, the port records the attacks in logs and sends Trap packets.

4.3.3 Configuring the Monitoring Period

Configures the monitoring period for an attacker.

Working Principle

Monitored hosts provide information about attackers in the current system. If the isolation period is 0 (that is, no isolation), the guard module automatically performs software monitoring on attackers in the configured monitoring period. Within the monitoring period, you can view the entries of a monitored host. If attacks are received from this host before aging of the monitoring period, refresh the monitoring period of the host; otherwise, when the monitoring period is aged to 0, the entries of the monitored host will be deleted. When the isolation time is configured to a non-0 value, the guard module automatically isolates the host monitored by the software.

4.3.4 Configuring the Isolation Period

Configure the isolation period for an attacker.

Working Principle

Isolation is performed by the guard policy after attacks are detected. Isolation is implemented using the filtering function of a software ACL to ensure that these attacks are not sent to the CPU, thereby ensuring proper running of the device.

The isolation function supports host-based and port-based isolation. When an attacker is isolated, a policy will be configured into an ACL. When the ACL resources are exhausted and isolation fails, logs will be printed to remind the administrator.

4.3.5 Configuring Trusted Hosts

Configure trusted hosts.

Working Principle

If you do not want to monitor a host, you can run the following commands to configure the host to be trusted. This trusted host will be allowed to send packets of specified types to the CPU.

4.3.6 Centralized Rate Limiting and Distribution

Set the rate thresholds and percentages for Manage, Route and Protocol packets.

Working Principle

Services defined in the CPP are classified into three types: Manage, Route, and Protocol. (For details, see the following table.) Each type of services has an independent bandwidth. Different types of services cannot share their bandwidths. Traffic exceeding the bandwidth threshold is discarded. By such service classification, service packets of a certain type can be processed first.

NFPP allows the administrator to flexibly assign bandwidth for three types of packets based on the actual network environment so that Protocol and Manage packets can be first processed. Prior processing of Protocol packets ensures proper running of the protocol, and prior processing of Manage packets helps the administrator perform proper management, thereby ensuring proper running of important device functions and improving the guard capability of the device.

After rate limiting for the preceding packet types, all types of packets are centralized in a queue. When one type of service features a lower processing efficiency, packets of this service will be backlogged in the queue and may finally use up resources of the queue. NFPP allows the administrator to configure the percentages of these three types of packets in the queue. When the queue length occupied by one type of packets exceeds the product of the total queue length and the percentage of this type of packets, these packets are discarded. This effectively prevents one type of packets from exclusively occupying queue resources.

Packet Type	Service Type Defined in the CPP
Protocol	tp-guard, dot1x, rldp, rerp, slow-packet, bpdu, isis dhcps, gvrp, ripng, dvmrp, igmp, mpls, ospf, pim, pimv6, rip, vrrp, ospf3, dhcp-relay-s, dhcp-relay-c, option82, tunnel-bpdu, and tunnel-gvrp
Route	unknown-ipmc, unknown-ipmcv6, ttl1, ttl0, udp-helper, ip4-packet-other, ip6-packet-other, and non-ip-packet-other
Manage	ip4-packet-local, ip6-packet-local, and arp

For the definitions of service types, see the *CPP Configuration Guide*.

4.4 Configuration

Configuration	Description and Command	
Configuring ARP Guard	(Mandatory) It is used to configure the global ARP guard function.	
	arp-guard enable	Enables global attack detection.
	arp-guard monitor-period	Configures the monitoring period.
	arp-guard monitored-host-limit	Configures the maximum number of monitored hosts.
	arp-guard rate-limit	Configures the global rate limit.
	arp-guard attack-threshold	Configures the global attack threshold.
	arp-guard scan-threshold	Configures the global host-based scanning threshold.

Configuration	Description and Command	
	(Optional) It is used to configure ARP isolation and ARP guard.	
	arp-guard isolate-period	Configures the global isolation period.
	arp-guard trusted-host	Configures trusted hosts.
	nfpp arp-guard enable	Enables attack detection for a port.
	nfpp arp-guard policy	Configures the rate limit and attack threshold for a port.
	nfpp arp-guard scan-threshold	Configures the stage-by-stage scanning threshold for a port.
	nfpp arp-guard isolate-period	Configures the isolation period for a port.
Configuring IP Anti-scanning	(Mandatory) It is used to configure the global IP anti-scanning function.	
	ip-guard enable	Enables global attack detection.
	ip-guard monitor-period	Configures the monitoring period.
	ip-guard monitored-host-limit	Configures the maximum number of monitored hosts.
	ip-guard rate-limit	Configures the global rate limit.
	ip-guard attack-threshold	Configures the global attack threshold.
	ip-guard scan-threshold	Configures the global host-based scanning threshold.
	(Optional) It is used to configure IP trusted hosts, IP isolation and port-based IP anti-scanning.	
	ip-guard isolate-period	Configures the global isolation period.
	ip-guard trusted-host	Configures trusted hosts.
	nfpp ip-guard enable	Enables attack detection for a port.
	nfpp ip-guard policy	Configures the rate limit and attack threshold for a port.
	nfpp ip-guard scan-threshold	Configures the stage-by-stage scanning threshold for a port.
	nfpp ip-guard isolate-period	Configures the isolation period for a port.
Configuring ICMP Guard	(Mandatory) It is used to configure the global ICMP guard function.	
	icmp-guard enable	Enables global attack detection.
	icmp-guard monitor-period	Configures the monitoring period.
	icmp-guard monitored-host-limit	Configures the maximum number of monitored hosts.
	icmp-guard rate-limit	Configures the global rate limit.
	icmp-guard attack-threshold	Configures the global attack threshold.

Configuration	Description and Command	
	(Optional) It is used to configure ICMP trusted hosts, ICMP isolation and port-based ICMP guard.	
	icmp-guard isolate-period	Configures the global isolation period.
	icmp-guard trusted-host	Configures trusted hosts.
	nfpp icmp-guard enable	Enables attack detection for a port.
	nfpp icmp-guard policy	Configures the rate limit and attack threshold for a port.
	nfpp icmp-guard isolate-period	Configures the isolation period for a port.
Configuring DHCP Guard	(Mandatory) It is used to configure the global DHCP guard function.	
	dhcp-guard enable	Enables global attack detection.
	dhcp-guard monitor-period	Configures the monitoring period.
	dhcp-guard monitored-host-limit	Configures the maximum number of monitored hosts.
	dhcp-guard rate-limit	Configures the global rate limit.
	dhcp-guard attack-threshold	Configures the global attack threshold.
	(Optional) It is used to configure DHCP isolation and port-based DHCP guard.	
	dhcp-guard isolate-period	Configures the global isolation period.
	dhcp-guard trusted-host	Configures trusted hosts.
	nfpp dhcp-guard enable	Enables attack detection for a port.
	nfpp dhcp-guard policy	Configures the rate limit and attack threshold for a port.
	nfpp dhcp-guard isolate-period	Configures the isolation period for a port.
Configuring DHCPv6 Guard	(Mandatory) It is used to configure the global DHCPv6 guard function.	
	dhcpv6-guard enable	Enables global attack detection.
	dhcpv6-guard monitor-period	Configures the monitoring period.
	dhcpv6-guard monitored-host-limit	Configures the maximum number of monitored hosts.
	dhcpv6-guard rate-limit	Configures the global rate limit.
	dhcpv6-guard attack-threshold	Configures the global attack threshold.
	(Optional) It is used to configure DHCPv6 isolation and DHCPv6 guard.	
	dhcpv6-guard isolate-period	Configures the global isolation period.
	dhcpv6-guard trusted-host	Configures trusted hosts.
	nfpp dhcpv6-guard enable	Enables attack detection for a port.
	nfpp dhcpv6-guard policy	Configures the rate limit and attack threshold for a port.
	nfpp dhcpv6-guard isolate-period	Configures the isolation period for a port.

Configuration	Description and Command	
Configuring ND Guard	(Mandatory) It is used to configure the global ND guard function.	
	nd-guard enable	Enables global attack detection.
	nd-guard rate-limit	Configures the global rate limit.
	nd-guard attack-threshold	Configures the global attack threshold.
	(Optional) It is used to configure the port-based ND guard function.	
	nd-guard trusted-host	Configures trusted hosts.
	nfpp nd-guard enable	Enables attack detection for a port.
	nfpp nd-guard policy	Configures the rate limit and attack threshold for a port.
Configuring Centralized Rate Limiting and Distribution	(Optional) It is used to set the rate thresholds and percentages for Manage, Route and Protocol packets.	
	cpu-protect sub-interface pps	Configures the maximum bandwidth for each type of packets.
	cpu-protect sub-interface percent	Configures the maximum percentage of each type of packets in the queue.
Configuring NFPP Log Information	(Mandatory) It is used to set log information.	
	log-buffer entries	Configures the capacity of NFPP log buffer.
	log-buffer logs	Configures the rate when logs are obtained from the log buffer to generate system messages.
	(Optional) It is used to set logs to be recorded.	
	logging vlan	Specifies the VLANs in which logs need to be recorded.
	logging interface	Specifies the port on which logs need to be recorded.

4.4.1 Configuring ARP Guard

Configuration Effect

- ARP attacks are identified based on hosts or ports. Host-based ARP attack identification supports two modes: identification based on the source IP address, VLAN ID, and port and identification based on the link-layer source MAC address, VLAN ID, and port. Each type of attack identification has a rate limit and an alarm threshold. If the ARP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ARP packet rate exceeds the alarm threshold, the system prints alarm information and sends Trap packets. In host-based attack identification, the system also isolates the attack source.

- ARP guard can also detect ARP scanning attacks. ARP scanning attacks indicate that the link-layer source MAC address is fixed but the source IP address changes, or that the link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes. Due to the possibility of misjudgment, hosts possibly performing ARP scanning are not isolated and are provided for the administrator's reference only.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.
- ARP guard prevents only ARP DoS attacks to the switch, but not ARP spoofing or ARP attacks in the network.

Configuration Steps

Enabling Attack Detection

- Mandatory.
- Support the global configuration mode or interface configuration mode on the AC device.
- If ARP guard is disabled, the system automatically clears monitored hosts, scanned hosts, and port isolation entries.

Command	**arp-guard enable**
Parameter Description	-
Defaults	ARP guard is enabled by default.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp arp-guard enable**
Parameter Description	-
Defaults	ARP guard is configured in global configuration mode, but not in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	ARP guard configured in interface configuration mode takes priority over that configured in global configuration mode.

Configuring the Isolation Period

- (Optional) Isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit, you can configure the isolation period to directly discard packets and therefore save bandwidth resources.
- Support the global configuration mode or interface configuration mode on the AC device.

- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored by software.

Command	**arp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. **permanent**: Indicates permanent isolation.
Defaults	The default global isolation period is 0, that is, no isolation.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp arp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. **permanent**: Indicates permanent isolation.
Defaults	By default, a global isolation period is used, but no local isolation period is configured.
Command Mode	Interface configuration mode
Usage Guide	-

Configuring the Monitoring Period

- Mandatory.
- If the isolation period is configured, it is directly used as the attacker monitoring period, and the configured monitoring period does not take effect.
- Support the global configuration mode on the AC device.

Command	**arp-guard monitor-period** *seconds*
Parameter Description	*seconds*: Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Defaults	The default monitoring period is 600 seconds.
Command Mode	NFPP configuration mode
Usage Guide	-

Configuring the Maximum Number of Monitored Hosts

- Mandatory.
- Configure the maximum number of monitored hosts. As the number of actually monitored hosts increases, more CPU resources are used to handle monitored hosts.
- Support the global configuration mode on the AC device.

- If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but prints the information "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that part of monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_ARP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Command	**arp-guard monitored-host-limit** *number*
Parameter Description	*number*: Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Defaults	The maximum number of monitored hosts is 1000 by default.
Command Mode	NFPP configuration mode
Usage Guide	-

Configuring the Attack Threshold

- Mandatory.
- To achieve the best ARP guard effect, you are advised to configure the host-based rate limit and alarm threshold based on the following rules: Source IP address-based rate limit < Source IP address-based alarm threshold < Source MAC address-based rate limit < Source MAC address-based alarm threshold.
- Support the global configuration mode or interface configuration mode on the AC device.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_ARP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes priority over source IP address-based rate limiting while the latter takes priority over port-based rate limiting.
- In NFPP configuration mode: run the **arp-guard rate-limit** {**per-src-ip** | **per-src-mac**} *pps* command to configure rate limits of hosts identified based on the source IP address, VLAN ID, and port and of hosts identified based on the link-layer source MAC address, VLAN ID, and port.
- In NFPP configuration mode: run the **arp-guard attack-threshold** {**per-src-ip** | **per-src-mac**} *pps* command to configure attack thresholds of hosts identified based on the source IP address, VLAN ID, and port and of hosts identified based on the link-layer source MAC address, VLAN ID, and port.
- In interface configuration mode: run the **nfpp arp-guard policy** {**per-src-ip | per-src-mac**} *rate-limit-pps attack-threshold-pps* command to configure rate limits and attack thresholds of hosts identified based on the source IP

address, VLAN ID, and port and of hosts identified based on the link-layer source MAC address, VLAN ID, and port on an interface.

Command	**arp-guard rate-limit** { **per-src-ip** | **per-src-mac** | **per-port** } *pps*
Parameter Description	**per-src-ip:** Limits the rate for each source IP address. **per-src-mac:** Limits the rate of packets from each source MAC address. **per-port:** Limits the rate for each port. *pps*: Indicates the rate limit, ranging from 1 to 9,999.
Defaults	the default rate limit varies with the product model.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**arp-guard attack-threshold** { **per-src-ip** | **per-src-mac | per-port** } *pps*
Parameter Description	**per-src-ip:** Configures the attack threshold for each source IP address. **per-src-mac:** Configures the attack threshold for each source MAC address. **per-port:** Configures the attack threshold for each port. *pps*: Indicates the attack threshold, ranging from 1 to 9,999. The unit is packets per second (pps).
Defaults	the default attack thresholds vary with the product model.
Command Mode	NFPP configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Command	**nfpp arp-guard policy** { **per-src-ip | per-src-mac | per-port** } *rate-limit-pps attack-threshold-pps*
Parameter Description	**per-src-ip:** Configures the rate limit and attack threshold for each source IP address. **per-src-mac:** Configures the rate limit and attack threshold for each source MAC address. **per-port:** Configures the rate limit and attack threshold for each port. *rate-limit-pps*: Indicates the rate limit, ranging from 1 to 9,999. *attack-threshold-pps*: Indicates the attack threshold, ranging from 1 to 9,999.
Defaults	By default, no rate limit and attack threshed are configured for a port, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuring the Scanning Threshold

- Mandatory.
- Support the global configuration mode or interface configuration mode on the AC device.
- The ARP scanning table stores only the latest 256 records. When the ARP scanning table is full, the latest record will overwrite the earliest record.

- ARP scanning attack may have occurred if ARP packets received within 10 seconds meet either of the following conditions:
  - The link-layer source MAC address is fixed but the source IP address changes.
  - The link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes, and the change times exceed the scanning threshold.

Command	**arp-guard scan-threshold** *pkt-cnt*
Parameter Description	*pkt-cnt*: Indicates the scanning threshold, ranging from 1 to 9,999.
Defaults	The default scanning threshold is 100 in the unit of 10 seconds.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp arp-guard scan-threshold** *pkt-cnt*
Parameter Description	*pkt-cnt*: Indicates the scanning threshold, ranging from 1 to 9,999.
Defaults	By default, no port-based ARP scanning threshold is configured and the global ARP scanning threshold is used.
Command Mode	Interface configuration mode
Usage Guide	-

Configuring Trusted Hosts

- (Optional) No trusted host is configured by default.
- For ARP guard, you can configure only a maximum of 500 IP addresses and MAC addresses not to be monitored.
- Support the global configuration mode on the AC device.
- If any entry matching a trusted host (the IP addresses and MAC addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.1 0000.0000.1111." to notify the administrator.
- If you fail to add a trusted host, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.1 0000.0000.1111." to notify the administrator.
- If the trusted host you want to add already exists, the system prints the log "%ERROR: Trusted host 1.1.1.1 0000.0000.1111 has already been configured." to notify the administrator.
- If the trusted host you want to delete does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.1 0000.0000.1111 is not found." to notify the administrator.

Command	**arp-guard trusted-host** *ip mac*
Parameter Description	*ip*: Indicates the IP address. *mac*: Indicates the MAC address.
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, you can run the following commands to configure the host to be trusted. This trusted host can send ARP packets to the CPU, without any rate limiting or alarm reporting.

Verification

When a network host sends ARP attack packets to a switch configured with ARP attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets not meeting trusted host configuration exceeds the attack threshold or scanning threshold, attack prompt information is displayed.
- If the rate of attack packets meets the trusted host configuration, no prompt information is displayed.

Configuration Example

↘ CPU Protection Based on ARP Guard

Scenario	● ARP host attacks exist in the system, and some hosts fail to properly establish an ARP connection. ● ARP scanning exists in the system, causing a very high CPU usage. ● ARP packet traffic of some hosts is very large in the system, and these packets need to pass through.
Configuration Steps	● Set the host-based attack threshold to 5 pps. ● Set the ARP scanning threshold to 10 pps. ● Set the isolation period to 180 pps. ● Configure trusted hosts.
	`Ruijie# configure terminal` `Ruijie(config)# nfpp` `Ruijie (config-nfpp)#arp-guard rate-limit per-src-mac 5` `Ruijie (config-nfpp)#arp-guard attack-threshold per-src-mac 10` `Ruijie (config-nfpp)#arp-guard isolate-period 180` `Ruijie (config-nfpp)#arp-guard trusted-host 1.1.1.1 0000.0000.1111`
Verification	● Run the **show nfpp arp-guard summary** command to display the configurations.
	`(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)` `Interface Status  Isolate-period Rate-limit  Attack-threshold Scan-threshold`

	Global Disable 180 4/5/100 8/10/200 15 Maximum count of monitored hosts: 1000 Monitor period: 600s
	● Run the **show nfpp arp-guard hosts** command to display monitored hosts.
	If col_filter 1 shows '*', it means "hardware do not isolate host". VLAN interface IP address MAC address remain-time(s) ---- --------- ---------- ---------- -------------- 1 Gi0/43 5.5.5.16 - 175 Total: 1 host
	● Run the **show nfpp arp-guard scan** command to display scanned hosts.
	VLAN interface IP address MAC address timestamp ---- --------- ---------- ---------- --------- 1 Gi0/5 - 001a.a9c2.4609 2013-4-30 23:50:32 1 Gi0/5 192.168.206.2 001a.a9c2.4609 2013-4-30 23:50:33 1 Gi0/5 - 001a.a9c2.4609 2013-4-30 23:51:33 1 Gi0/5 192.168.206.2 001a.a9c2.4609 2013-4-30 23:51:34 Total: 4 record(s)
	● Run the **show nfpp arp-guard trusted-host** command to display trusted hosts.
	IP address mac ---------- ---- 1.1.1.1 0000.0000.1111 Total: 1 record(s)

4.4.2 Configuring IP Anti-scanning

Configuration Effect

- IP attacks are identified based on hosts or ports. In host-based IP attack identification, IP attacks are identified based on the source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an alarm threshold. If the IP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the IP packet rate exceeds the alarm threshold, the system prints alarm information and sends Trap packets. In host-based attack identification, the system also isolates the attack source.

- IP guard can also detect IP scanning attacks. IP anti-scanning applies to IP packet attacks as follows: the destination IP address continuously changes but the source IP address remains the same, and the destination IP address is not the IP address of the local device.
- IP anti-scanning applies to IP packet attacks where the destination IP address is not the local IP address. The CPP limits the rate of IP packets where the destination IP address is the local IP address.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.

Configuration Steps

Enabling Attack Detection

- (Mandatory) Attack detection is enabled by default.
- Support the global configuration mode or interface configuration mode on the AC device.
- If IP anti-scanning is disabled, the system automatically clears monitored hosts.

Command	**ip-guard enable**
Parameter Description	-
Defaults	IP anti-scanning is enabled by default.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp ip-guard enable**
Parameter Description	-
Defaults	IP anti-scanning is configured in global configuration mode, but not in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	IP anti-scanning configured in interface configuration mode takes priority over that configured in global configuration mode.

Configuring the Isolation Period

- (Optional) Isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit of the CPP, you can configure the isolation period to directly discard packets and therefore save bandwidth resources.
- Support the global configuration mode or interface configuration mode on the AC device.

- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored by software.

Command	**ip-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. **permanent**: Indicates permanent isolation.
Defaults	The default global isolation period is 0, that is, no isolation.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp ip-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. **permanent**: Indicates permanent isolation.
Defaults	By default, a global isolation period is used, but no local isolation period is configured.
Command Mode	Interface configuration mode
Usage Guide	-

Configuring the Monitoring Period

- Mandatory.
- If the isolation period is configured, it is directly used as the attacker monitoring period, and the configured monitoring period does not take effect.
- Support the global configuration mode on the AC device.

Command	**ip-guard monitor-period** *seconds*
Parameter Description	*seconds*: Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Defaults	The default monitoring period is 600 seconds.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored by software.

Configuring the Maximum Number of Monitored Hosts

- Mandatory.
- Increase the maximum number of monitored hosts. As the number of actually monitored hosts increases, more CPU resources are used to handle monitored hosts.

- Support the global configuration mode on the AC device.
- If the number of monitored hosts reaches 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but prints the information "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that part of monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_IP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Command	**ip-guard monitored-host-limit** *number*
Parameter Description	*number*: Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Defaults	The maximum number of monitored hosts is 1000 by default.
Command Mode	NFPP configuration mode
Usage Guide	-

Configuring the Attack Threshold

- Mandatory.
- Support the global configuration mode or interface configuration mode on the AC device.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_IP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source IP address-based rate limiting takes priority over port-based rate limiting.
- In NFPP configuration mode: run the **ip-guard rate-limit** { **per-src-ip** | **per-port** } *pps* command to configure the global rate limit.
- In NFPP configuration mode: run the **ip-guard attack-threshold** { **per-src-ip** | **per-port** } *pps* command to configure the global attack threshold. That is, when the packet rate exceeds the attack threshold, it is considered that attack behaviors exist.
- In interface configuration mode: run the **nfpp ip-guard policy** { **per-src-ip | per-port** } *rate-limit-pps attack-threshold-pps* command to configure the local rate limit and attack threshold on a port.

Command	**ip-guard rate-limit** { **per-src-ip**	**per-port** } *pps*
Parameter Description	**per-src-ip:** Limits the rate for each source IP address. **per-port:** Limits the rate for each port. *pps*: Indicates the rate limit, ranging from 1 to 9,999.

Defaults	**per-src-ip**: 20 pps. **per-port**: 1,500 pps.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**ip-guard attack-threshold** { **per-src-ip** | **per-port** } *pps*
Parameter Description	**per-src-ip:** Configures the attack threshold for each source IP address. **per-port:** Configures the attack threshold for each port. *pps*: Indicates the attack threshold, ranging from 1 to 9,999. The unit is pps.
Defaults	**per-src-ip**: 20 pps. **per-port**: 1,500 pps.
Command Mode	NFPP configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Command	**nfpp ip-guard policy** { **per-src-ip | per-port** } *rate-limit-pps attack-threshold-pps*
Parameter Description	**per-src-ip:** Configures the attack threshold for each source IP address. **per-port:** Configures the attack threshold for each port. *rate-limit-pps*: Indicates the rate limit, ranging from 1 to 9,999. *attack-threshold-pps*: Indicates the attack threshold, ranging from 1 to 9,999.
Defaults	By default, no rate limit and attack threshed are configured for a port, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuring the Scanning Threshold

- Mandatory.
- Support the global configuration mode or interface configuration mode on the AC device.
- IP scanning attack may have occurred if IP packets received within 10 seconds meet the following conditions:
  - The source IP address remains the same.
  - The destination IP address continuously changes and is not the local IP address, and the change times exceed the scanning threshold.

Command	**ip-guard scan-threshold** *pkt-cnt*
Parameter Description	*pkt-cnt*: Indicates the scanning threshold, ranging from 1 to 9,999.
Defaults	The default scanning threshold is 100 pps.

Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp ip-guard scan-threshold** *pkt-cnt*
Parameter Description	*pkt-cnt*: Indicates the scanning threshold, ranging from 1 to 9,999.
Defaults	By default, no port-based IP scanning threshold is configured and the global IP scanning threshold is used.
Command Mode	Interface configuration mode
Usage Guide	-

Configuring Trusted Hosts

- (Optional) No trusted host is configured by default.
- For IP anti-scanning, you can configure a maximum of 500 IP addresses not to be monitored.
- Support the global configuration mode on the AC device.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If you fail to add a trusted host, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the trusted host you want to add already exists, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the trusted host you want to delete does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.

Command	**ip-guard trusted-host** *ip mask*
Parameter Description	*ip*: Indicates the IP address. *mask*: Indicates the mask of an IP address.
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, you can run the following commands to configure the host to be trusted. This trusted host can send IP packets to the CPU, without any rate limiting or alarm reporting.

Verification

When a network host sends IP attack packets to a switch configured with IP attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets not meeting trusted host configuration exceeds the attack threshold or scanning threshold, attack prompt information is displayed.
- If the rate of attack packets meets the trusted host configuration, no prompt information is displayed.

Configuration Example

↘ CPU Protection Based on IP Guard

Scenario	● IP host attacks exist in the system, and packets of some hosts cannot be properly routed and forwarded. ● IP scanning exists in the system, causing a very high CPU usage. ● Packet traffic of some hosts is very large in the system, and these packets need to pass through.
Configuration Steps	● Configure the host-based attack threshold. ● Configure the IP scanning threshold. ● Set the isolation period to a non-zero value. ● Configure trusted hosts.
	`Ruijie# configure terminal` `Ruijie(config)# nfpp` `Ruijie (config-nfpp)#ip-guard rate-limit per-src-ip 20` `Ruijie (config-nfpp)#ip-guard attack-threshold per-src-ip 30` `Ruijie (config-nfpp)#ip-guard isolate-period 180` `Ruijie (config-nfpp)#ip-guard trusted-host 192.168.201.46 255.255.255.255`
Verification	● Run the **show nfpp ip-guard summary** command to display the configurations.
	(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.) `Interface Status Isolate-period Rate-limit Attack-threshold Scan-threshold` `Global Disable 180 20/-/100 30/-/200 100` Maximum count of monitored hosts: 1000 Monitor period: 600s
	● Run the show nfpp ip-guard hosts command to display monitored hosts.
	`If col_filter 1 shows '*', it means "hardware do not isolate host".` `VLAN interface IP address Reason remain-time(s)`

	`` ---- --------- ---------- ------ -------------- 1 Gi0/5 192.168.201.47 ATTACK 160 Total: 1 host ```
	● Run the **show nfpp ip-guard trusted-host** command to display trusted hosts.
	`` IP address mask ---------- ---- 192.168.201.46 255.255.255.255 Total: 1 record(s) ```

4.4.3 Configuring ICMP Guard

Configuration Effect

- ICMP attacks are identified based on hosts or ports. In host-based attack identification, ICMP attacks are identified based on the source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an alarm threshold. If the ICMP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ICMP packet rate exceeds the alarm threshold, the system prints alarm information and sends Trap packets. In host-based attack identification, the system also isolates the attack source.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.

Configuration Steps

↘ Enabling Attack Detection

- (Mandatory) Attack detection is enabled by default.
- Support the global configuration mode or interface configuration mode on the AC device.
- If ICMP guard is disabled, the system automatically clears monitored hosts.

Command	**icmp-guard enable**
Parameter Description	-
Defaults	ICMP guard is enabled by default.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp icmp-guard enable**
Parameter Description	-
Defaults	ICMP guard is configured in global configuration mode, but not in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	ICMP guard configured in interface configuration mode takes priority over that in global configuration mode.

Configuring the Isolation Period

- (Optional) Isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit of the CPP, you can configure the isolation period to directly discard packets and therefore save bandwidth resources.
- Support the global configuration mode or interface configuration mode on the AC device.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored by software.

Command	**icmp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	The default global isolation period is 0, that is, no isolation.
Command Mode	NFPP configuration mode
Usage Guide	The attacker isolation period falls into two types: global isolation period and port-based isolation period (local isolation period). For a port, if the port-based isolation period is not configured, the global isolation period is used; otherwise, the port-based isolation period is used.

Command	**nfpp icmp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	By default, a global isolation period is used, but no local isolation period is configured.
Command Mode	Interface configuration mode
Usage Guide	-

Configuring the Monitoring Period

- Mandatory.
- If the isolation period is configured, it is directly used as the attacker monitoring period, and the configured monitoring period does not take effect.

- Support the global configuration mode on the AC device.

Command	**icmp-guard monitor-period** *seconds*
Parameter Description	*seconds*: Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Defaults	The default monitoring period is 600 seconds.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs isolation against attackers monitored by software and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0. If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored by software.

Configuring the Maximum Number of Monitored Hosts

- Mandatory.
- Increase the maximum number of monitored hosts. As the number of actually monitored hosts increases, more CPU resources are used to handle monitored hosts.
- Support the global configuration mode on the AC device.
- If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but prints the information "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that part of monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_ICMP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Command	**icmp-guard monitored-host-limit** *number*
Parameter Description	*number*: Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Defaults	The maximum number of monitored hosts is 1000 by default.
Command Mode	NFPP configuration mode
Usage Guide	If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but prints the information "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that part of monitored hosts need to be deleted. If the table of monitored hosts is full, the system prints the log "% NFPP_ICMP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Configuring the Attack Threshold

- Mandatory.
- Support the global configuration mode or interface configuration mode on the AC device.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_ICMP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source IP address-based rate limiting takes priority over port-based rate limiting.
- In NFPP configuration mode: run the **icmp-guard rate-limit** { **per-src-ip** | **per-port** } *pps* command to configure the global rate limit.
- In NFPP configuration mode: run the **icmp-guard attack-threshold** { **per-src-ip** | **per-port** } *pps* command to configure the global attack threshold. That is, when the packet rate exceeds the attack threshold, it is considered that attack behaviors exist.
- In interface configuration mode: run the **nfpp icmp-guard policy** { **per-src-ip | per-port** } *rate-limit-pps attack-threshold-pps* command to configure the local rate limit and attack threshold on a port.

Command	**icmp-guard rate-limit** { **per-src-ip** | **per-port** } *pps*
Parameter Description	**per-src-ip:** Limits the rate for each source IP address. **per-port:** Limits the rate for each port. *pps*: Indicates the rate limit, ranging from 1 to 9,999.
Defaults	For the AC devices, see the specification and limitation document. For the AP device: **per-src-ip**: 200 pps; **per-port**: 400 pps.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**icmp-guard attack-threshold** { **per-src-ip** | **per-port** } *pps*
Parameter Description	**per-src-ip:** Configures the attack threshold for each source IP address. **per-port:** Configures the attack threshold for each port. *pps*: Indicates the attack threshold, ranging from 1 to 9,999. The unit is pps.
Defaults	For the AC devices, see the specification and limitation document. For the AP device: **per-src-ip**: 200 pps; **per-port**: 400 pps.

Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp icmp-guard policy** { **per-src-ip | per-port** } *rate-limit-pps attack-threshold-pps*
Parameter Description	**per-src-ip:** Configures the rate limit and attack threshold for each source IP address. **per-port:** Configures the rate limit and attack threshold for each port. *rate-limit-pps*: Indicates the rate limit, ranging from 1 to 9,999. *attack-threshold-pps*: Indicates the attack threshold, ranging from 1 to 9,999.
Defaults	By default, no rate limit and attack threshed are configured for a port, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuring Trusted Hosts

- (Optional) No trusted host is configured by default.
- For ICMP anti-scanning, you can configure a maximum of 500 IP addresses not to be monitored.
- Support the global configuration mode on the AC device.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If you fail to add a trusted host, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the trusted host you want to add already exists, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the trusted host you want to delete does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.

Command	**icmp-guard trusted-host** *ip mask*
Parameter Description	*ip*: Indicates the IP address. *mask*: Indicates the mask of an IP address.
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode

Usage Guide	If you do not want to monitor a host, you can run the following commands to configure the host to be trusted. This trusted host can send ICMP packets to the CPU, without any rate limiting or alarm reporting. You can configure the mask so that no host in one network segment is monitored. You can configure a maximum of 500 trusted hosts.

Verification

When a network host sends ICMP attack packets to a switch configured with ICMP attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets not meeting trusted host configuration exceeds the attack threshold, attack prompt information is displayed.
- If the rate of attack packets meets the trusted host configuration, no prompt information is displayed.

Configuration Example

↘ CPU Protection Based on ICMP Guard

Scenario	● ICMP host attacks exist in the system, and some hosts cannot successfully ping devices. ● Packet traffic of some hosts is very large in the system, and these packets need to pass through.
Configuration Steps	● Configure the host-based attack threshold. ● Set the isolation period to a non-zero value. ● Configure trusted hosts.
	`Ruijie# configure terminal` `Ruijie(config)# nfpp` `Ruijie (config-nfpp)#icmp-guard rate-limit per-src-ip 20` `Ruijie (config-nfpp)#icmp-guard attack-threshold per-src-ip 30` `Ruijie (config-nfpp)#icmp-guard isolate-period 180` `Ruijie (config-nfpp)#icmp-guard trusted-host 192.168.201.46 255.255.255.255`
Verification	● Run the **show nfpp icmp-guard summary** command to display the configurations.
	`(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)` `Interface Status  Isolate-period Rate-limit  Attack-threshold` `Global  Disable 180  20/-/400  30/-/400` `Maximum count of monitored hosts: 1000` `Monitor period: 600s`
	● Run the **show nfpp icmp-guard hosts** command to display monitored hosts.

	If col_filter 1 shows '*', it means "hardware do not isolate host". VLAN interface IP address remain-time(s) ---- --------- ---------- -------------- 1 Gi0/5 192.168.201.47 160 Total: 1 host
	• Run the **show nfpp icmp-guard trusted-host** command to display trusted hosts.
	IP address mask ---------- ---- 192.168.201.46 255.255.255.255 Total: 1 record(s)

4.4.4 Configuring DHCP Guard

Configuration Effect

- DHCP attacks are identified based on hosts or ports. In host-based attack identification, DHCPv6 attacks are identified based on the link-layer source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an alarm threshold. If the DHCP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the DHCP packet rate exceeds the alarm threshold, the system prints alarm information and sends Trap packets. In host-based attack identification, the system also isolates the attack source.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.

Configuration Steps

↘ Enabling Attack Detection

- (Mandatory) Attack detection is enabled by default.
- Support the global configuration mode or interface configuration mode on the AC device.
- If DHCP guard is disabled, the system automatically clears monitored hosts.

Command	**dhcp-guard enable**
Parameter Description	-
Defaults	Attack detection is enabled by default.
Command Mode	NFPP configuration mode

Usage Guide	-

Command	**nfpp dhcp-guard enable**
Parameter Description	-
Defaults	DHCP guard is configured in global configuration mode, but not in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	DHCP guard configured in interface configuration mode takes priority over that configured in global configuration mode.

Configuring the Isolation Period

- (Optional) Isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit of the CPP, you can configure the isolation period to directly discard packets and therefore save bandwidth resources.
- Support the global configuration mode or interface configuration mode on the AC device.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored by software.

Command	**dhcp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	The default global isolation period is 0, that is, no isolation.
Command Mode	NFPP configuration mode
Usage Guide	The attacker isolation period falls into two types: global isolation period and port-based isolation period (local isolation period). For a port, if the port-based isolation period is not configured, the global isolation period is used; otherwise, the port-based isolation period is used.

Command	**nfpp dhcp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	By default, a global isolation period is used, but no local isolation period is configured.
Command Mode	Interface configuration mode
Usage Guide	-

Configuring the Monitoring Period

- Mandatory.
- If the isolation period is configured, it is directly used as the attacker monitoring period, and the configured monitoring period does not take effect.
- Support the global configuration mode on the AC device.

Command	**dhcp-guard monitor-period** *seconds*
Parameter Description	*seconds*: Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Defaults	The default monitoring period is 600 seconds.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs isolation against attackers monitored by software and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0. If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored by software.

Configuring the Maximum Number of Monitored Hosts

- Mandatory.
- Increase the maximum number of monitored hosts. As the number of actually monitored hosts increases, more CPU resources are used to handle monitored hosts.
- Support the global configuration mode on the AC device.
- If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but prints the information "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that part of monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_DHCP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Command	**dhcp-guard monitored-host-limit** *number*
Parameter Description	*number*: Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Defaults	The maximum number of monitored hosts is 1000 by default.
Command Mode	NFPP configuration mode
Usage Guide	If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but prints the information "%ERROR: The value that you configured is smaller than current monitored

	hosts 1000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that part of monitored hosts need to be deleted. If the table of monitored hosts is full, the system prints the log "% NFPP_DHCP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Configuring the Attack Threshold

- Mandatory.
- Support the global configuration mode or interface configuration mode on the AC device.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_DHCP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes priority over port-based rate limiting.
- In NFPP configuration mode: run the **dhcp-guard rate-limit** { **per-src-mac** | **per-port** } *pps* command to configure the global rate limit.
- In NFPP configuration mode: run the **dhcp-guard attack-threshold** { **per-src-mac** | **per-port** } *pps* command to configure the global attack threshold. That is, when the packet rate exceeds the attack threshold, it is considered that attack behaviors exist.
- In interface configuration mode: run the **nfpp dhcp-guard policy** { **per-src-mac | per-port** } *rate-limit-pps attack-threshold-pps* command to configure the local rate limit and attack threshold on a port.

Command	**dhcp-guard rate-limit** { **per-src-mac**	**per-port** } *pps*
Parameter Description	**per-src-mac:** Limits the rate for each source MAC address. **per-port:** Limits the rate for each port. *pps*: Indicates the rate limit, ranging from 1 to 9,999.
Defaults	For the AC devices, the default rate limit varies with the product model. For the AP devices, the default rate limit for packets based on source MAC address is 5 pps, and the default rate limit for packets based on port is 150 pps.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**dhcp-guard attack-threshold** { **per-src-mac**	**per-port** } *pps*
Parameter Description	**per-src-mac:** Configures the attack threshold for each source MAC address. **per-port:** Configures the attack threshold for each port.

	pps: Indicates the attack threshold, ranging from 1 to 9,999. The unit is pps.
Defaults	For the AC devices, the default rate limit varies with the product model. For the AP devices, the default rate limit for packets based on source MAC address is 10 pps, and the default rate limit for packets based on port is 300 pps.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp dhcp-guard policy** { **per-src-mac | per-port** } *rate-limit-pps attack-threshold-pps*
Parameter Description	**per-src-mac:** Configures the rate limit and attack threshold for each source MAC address**.** **per-port:** Configures the rate limit and attack threshold for each port. *rate-limit-pps*: Indicates the rate limit, ranging from 1 to 9,999. *attack-threshold-pps*: Indicates the attack threshold, ranging from 1 to 9,999.
Defaults	By default, no rate limit and attack threshed are configured for a port, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuring Trusted Hosts

- (Optional) No trusted host is configured by default.
- For DHCP guard, you can configure a maximum of 500 MAC addresses not to be monitored.
- Support the global configuration mode on the AC device.
- If any entry matching a trusted host (MAC addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system prints the log "%ERROR: Failed to delete trusted host 0000.0000.1111." to notify the administrator.
- If you fail to add a trusted host, the system prints the log "%ERROR: Failed to add trusted host 0000.0000.1111." to notify the administrator.
- If the trusted host you want to add already exists, the system prints the log "%ERROR: Trusted host 0000.0000.1111 has already been configured." to notify the administrator.
- If the trusted host you want to delete does not exist, the system prints the log "%ERROR: Trusted host 0000.0000.1111 is not found." to notify the administrator.

Command	**dhcp-guard trusted-host** *mac*
Parameter	*mac*: Indicates the MAC address.

Description	
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, you can run the following commands to configure the host to be trusted. This trusted host can send DHCP packets to the CPU, without any rate limiting or alarm reporting.

Verification

When a network host sends DHCP attack packets to a switch configured with DHCP attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets not meeting trusted host configuration exceeds the attack threshold or scanning threshold, attack prompt information is displayed.
- If the rate of attack packets meets the trusted host configuration, no prompt information is displayed.

Configuration Example

CPU Protection Based on DHCP Guard

Scenario	DHCP host attacks exist in the system, and some hosts fail to request IP addresses. DHCP packet traffic of some hosts is very large in the system, and these packets need to pass through.
Configuration Steps	● Configure the host-based attack threshold. ● Set the isolation period to a non-zero value. ● Configure trusted hosts.
	`Ruijie# configure terminal` `Ruijie(config)# nfpp` `Ruijie (config-nfpp)#dhcp-guard rate-limit per-src-mac 8` `Ruijie (config-nfpp)#dhcp-guard attack-threshold per-src-mac 16` `Ruijie (config-nfpp)#dhcp-guard isolate-period 180` `Ruijie (config-nfpp)#dhcp-guard trusted-host 0000.0000.1111`
Verification	● Run the **show nfpp dhcp-guard summary** command to display the configurations.
	`(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)` `Interface Status  Isolate-period Rate-limit  Attack-threshold` `Global  Disable 180  -/8/150  -/16/300` `Maximum count of monitored hosts: 1000`

	Monitor period: 600s
	• Run the **show nfpp dhcp-guard hosts** command to display monitored hosts.
	If col_filter 1 shows '*', it means "hardware do not isolate host". VLAN interface MAC address remain-time(s) ---- --------- ----------- -------------- *1 Gi0/5 001a.a9c2.4609 160 Total: 1 host
	• Run the **show nfpp dhcp-guard trusted-host** command to display trusted hosts.
	mac ---- 0000.0000.1111 Total: 1 record(s)

4.4.5 Configuring DHCPv6 Guard

Configuration Effect

- DHCPv6 attacks are identified based on hosts or ports. In host-based attack identification, DHCPv6 attacks are identified based on the link-layer source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an alarm threshold. If the DHCPv6 packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the DHCPv6 packet rate exceeds the alarm threshold, the system prints alarm information and sends Trap packets.
- In host-based attack identification, the system also isolates the attack source.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.

Configuration Steps

↘ Enabling Attack Detection

- (Mandatory) Attack detection is enabled by default.
- Support the global configuration mode or interface configuration mode on the AC device.
- If DHCPv6 guard is disabled, the system automatically clears monitored hosts.

Command	**dhcpv6-guard enable**
Parameter	-

Description	
Defaults	Attack detection is enabled by default.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp dhcpv6-guard enable**
Parameter Description	-
Defaults	DHCPv6 guard is configured in global configuration mode, but not in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	DHCPv6 guard configured in interface configuration mode takes priority over that configured in global configuration mode.

Configuring the Isolation Period

- (Optional) Isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit of the CPP, you can configure the isolation period to directly discard packets and therefore save bandwidth resources.
- Support the global configuration mode or interface configuration mode on the AC device.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored by software.

Command	**dhcpv6-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	The default global isolation period is 0, that is, no isolation.
Command Mode	NFPP configuration mode
Usage Guide	The attacker isolation period falls into two types: global isolation period and port-based isolation period (local isolation period). For a port, if the port-based isolation period is not configured, the global isolation period is used; otherwise, the port-based isolation period is used.

Command	**nfpp dhcpv6-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	By default, a global isolation period is used, but no local isolation period is configured.

Command Mode	Interface configuration mode
Usage Guide	-

Configuring the Monitoring Period

- Mandatory.
- If the isolation period is configured, it is directly used as the attacker monitoring period, and the configured monitoring period does not take effect.
- Support the global configuration mode on the AC device.

Command	**dhcpv6-guard monitor-period** *seconds*
Parameter Description	*seconds*: Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Defaults	The default monitoring period is 600 seconds.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs isolation against attackers monitored by software and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0. If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored by software.

Configuring the Maximum Number of Monitored Hosts

- Mandatory.
- Increase the maximum number of monitored hosts. As the number of actually monitored hosts increases, more CPU resources are used to handle monitored hosts.
- Support the global configuration mode on the AC device.
- If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but prints the information "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that part of monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_DHCPV6_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Command	**dhcpv6-guard monitored-host-limit** *number*
Parameter Description	*number*: Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Defaults	The maximum number of monitored hosts is 1000 by default.

Command Mode	NFPP configuration mode
Usage Guide	If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but prints the information "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that part of monitored hosts need to be deleted. If the table of monitored hosts is full, the system prints the log "% NFPP_DHCPV6_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Configuring the Attack Threshold

- Mandatory.
- Support the global configuration mode or interface configuration mode on the AC device.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_DHCPV6_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes priority over port-based rate limiting.
- In NFPP configuration mode: run the **dhcpv6-guard rate-limit** { **per-src-mac** | **per-port** } *pps* command to configure the global rate limit.
- In NFPP configuration mode: run the **dhcpv6-guard attack-threshold** { **per-src-mac** | **per-port** } *pps* command to configure the global attack threshold. That is, when the packet rate exceeds the attack threshold, it is considered that attack behaviors exist.
- In interface configuration mode: run the **nfpp dhcpv6-guard policy** { **per-src-mac | per-port** } *rate-limit-pps attack-threshold-pps* command to configure the local rate limit and attack threshold on a port.

Command	**dhcpv6-guard rate-limit** { **per-src-mac**	**per-port** } *pps*
Parameter Description	**per-src-mac:** Limits the rate for each source MAC address. **per-port:** Limits the rate for each port. *pps*: Indicates the rate limit, ranging from 1 to 9,999.
Defaults	For the AC devices, the default rate limit varies with the product model. For the AP devices, the default rate limit for packets based on source MAC address is 5 pps, and the default rate limit for packets based on port is 150 pps.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**dhcpv6-guard attack-threshold** { **per-src-mac** | **per-port** } *pps*
Parameter Description	**per-src-mac:** Configures the attack threshold for each source MAC address. **per-port:** Configures the attack threshold for each port. *pps*: Indicates the attack threshold, ranging from 1 to 9,999. The unit is pps.
Defaults	For the AC devices, the default rate limit varies with the product model. For the AP devices, the default rate limit for packets based on source MAC address is 10 pps, and the default rate limit for packets based on port is 300 pps.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp dhcpv6-guard policy** { **per-src-mac** | **per-port** } *rate-limit-pps attack-threshold-pps*
Parameter Description	**per-src-mac:** Configures the rate limit and attack threshold for each source MAC address. **per-port:** Configures the rate limit and attack threshold for each port. *rate-limit-pps*: Indicates the rate limit, ranging from 1 to 9,999. *attack-threshold-pps*: Indicates the attack threshold, ranging from 1 to 9,999.
Defaults	By default, no rate limit and attack threshed are configured for a port, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuring Trusted Hosts

- (Optional) No trusted host is configured by default.
- For DHCPv6 guard, you can configure a maximum of 500 MAC addresses not to be monitored.
- Support the global configuration mode on the AC device.
- If any entry matching a trusted host (MAC addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system prints the log "%ERROR: Failed to delete trusted host 0000.0000.1111." to notify the administrator.
- If you fail to add a trusted host, the system prints the log "%ERROR: Failed to add trusted host 0000.0000.1111." to notify the administrator.
- If the trusted host you want to add already exists, the system prints the log "%ERROR: Trusted host 0000.0000.1111 has already been configured." to notify the administrator.

- If the trusted host you want to delete does not exist, the system prints the log "%ERROR: Trusted host 0000.0000.1111 is not found." to notify the administrator.

Command	**dhcpv6-guard trusted-host** *mac*
Parameter Description	*mac*: Indicates the MAC address.
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, you can run the following commands to configure the host to be trusted. This trusted host can send DCHPv6 packets to the CPU, without any rate limiting or alarm reporting.

Verification

When a network host sends DHCPv6 attack packets to a switch configured with DHCPv6 attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets not meeting trusted host configuration exceeds the attack threshold or scanning threshold, attack prompt information is displayed.
- If an isolation entry needs to be created for the attacker, attacker isolation prompt information is displayed.

Configuration Example

CPU Protection Based on DHCPv6 Guard

Scenario	DHCPv6 host attacks exist in the system, and DHCPv6 neighbor discovery fails on some hosts. DHCPv6 packet traffic of some hosts is very large in the system, and these packets need to pass through.
Configuration Steps	● Configure the host-based attack threshold. ● Set the isolation period to a non-zero value. ● Configure trusted hosts.
	`Ruijie# configure terminal` `Ruijie(config)# nfpp` `Ruijie (config-nfpp)#dhcpv6-guard rate-limit per-src-mac 8` `Ruijie (config-nfpp)#dhcpv6-guard attack-threshold per-src-mac 16` `Ruijie (config-nfpp)#dhcpv6-guard isolate-period 180` `Ruijie (config-nfpp)#dhcpv6-guard trusted-host 0000.0000.1111`
Verification	● Run the **show nfpp dhcpv6-guard summary** command to display the configurations.
	`(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)` `Interface Status  Isolate-period Rate-limit  Attack-threshold`

	Global Disable 180 -/8/150 -/16/300 Maximum count of monitored hosts: 1000 Monitor period: 600s
	● Run the **show nfpp dhcpv6-guard hosts** command to display monitored hosts.
	If col_filter 1 shows '*', it means "hardware do not isolate host". VLAN interface MAC address remain-time(s) ---- --------- ----------- -------------- *1 Gi0/5 001a.a9c2.4609 160 Total: 1 host
	● Run the **show nfpp dhcpv6-guard trusted-host** command to display trusted hosts.
	mac ---- 0000.0000.1111 Total: 1 record(s)

4.4.6 Configuring ND Guard

Configuration Effect

- AR ND guard classifies ND packets into three types based on their purposes: 1. NS and NA; 2. RS; 3. RA and Redirect. The first type of packets are used for address resolution. The second type of packets are used by hosts to discover the gateway. The third type of packets are related to routing: RAs are used to advertise the gateway and prefix while Redirect packets are used to advertise a better next hop.
- At present, only port-based ND packet attack identification is supported. You can configure the rate limits and alarm thresholds for these three types of packets. If the ND packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ND packet rate exceeds the alarm threshold, the system prints alarm information and sends Trap packets.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.

Configuration Steps

↘ **Enabling Attack Detection**

- (Mandatory) Attack detection is enabled by default.
- Support the global configuration mode or interface configuration mode on the AC device.

Command	**nd-guard enable**
Parameter Description	-
Defaults	ND guard is enabled by default.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp nd-guard enable**
Parameter Description	-
Defaults	ND guard is configured in global configuration mode, but not in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	ND guard configured in interface configuration mode takes priority over that configured in global configuration mode.

Configuring the Attack Threshold

- Mandatory.
- Support the global configuration mode or interface configuration mode on the AC device.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_ND_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- In NFPP configuration mode: run the **nd-guard rate-limit per-port** [**ns-na** | **rs** | **ra-redirect**] *pps* command to configure the global rate limit.
- In NFPP configuration mode: run the **nd-guard attack-threshold per-port** [**ns-na** | **rs** | **ra-redirect**] *pps* command to configure the global attack threshold. That is, when the packet rate exceeds the attack threshold, it is considered that attack behaviors exist.
- In interface configuration mode: run the **nfpp nd-guard policy per-port** [**ns-na** | **rs** | **ra-redirect**] *rate-limit-pps attack-threshold-pps* command to configure the local rate limit and attack threshold on a port.

Command	**nd-guard rate-limit per-port** [**ns-na**	**rs**	**ra-redirect**] *pps*
Parameter	**ns-na:** Indicates NSs and NAs.

Description	**rs:** Indicates RSs. **ra-redirect:** Indicates RAs and Redirect packets. *pps*: Indicates the rate limit, ranging from 1 to 9,999.
Defaults	For the AC devices, the default attack threshold varies with the product model. For the AP devices, the default attack threshold for ns-na, rs, and ra-redirect packets is 15 pps.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nd-guard attack-threshold per-port** [**ns-na** | **rs** | **ra-redirect**] *pps*
Parameter Description	**ns-na:** Indicates NSs and NAs. **rs:** Indicates RSs. **ra-redirect:** Indicates RAs and Redirect packets. *pps*: Indicates the attack threshold, ranging from 1 to 9,999. The unit is pps.
Defaults	For the AC devices, the default attack threshold varies with the product model. For the AP devices, the default attack threshold for ns-na, rs, and ra-redirect packets is 30 pps.
Command Mode	NFPP configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Command	**nfpp nd-guard policy per-port** [**ns-na** | **rs** | **ra-redirect**] *rate-limit-pps attack-threshold-pps*
Parameter Description	**ns-na:** Indicates NSs and NAs. **rs:** Indicates RSs. **ra-redirect:** Indicates RAs and Redirect packets. *rate-limit-pps*: Indicates the rate limit, ranging from 1 to 9,999. *attack-threshold-pps*: Indicates the attack threshold, ranging from 1 to 9,999.
Defaults	By default, no rate limit and attack threshed are configured for a port, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit. ND snooping classifies ports into two types: untrusted ports (connecting the host) and trusted ports (connecting to the gateway). As traffic on a trusted port is usually larger than that on an untrusted port, the rate limit for a trusted port is higher than that for an untrusted port. If ND snooping is enabled for a trusted port, ND snooping sets the rate limit to 800 pps and the attack threshold to 900 pps for the three types of packets on the port by advertising ND guard. ND guard treats the rate limit configured for ND snooping and that configured by the administrator in the same way. The value configured later overwrites the value configured earlier and is stored in the configuration file. The attack threshold configured for ND snooping is treated in a similar way.

Configuring Trusted Hosts

- (Optional) No trusted host is configured by default.
- For ND guard, you can configure a maximum of 500 MAC addresses not to be monitored.
- Support the global configuration mode on the AC or AP device.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system prints the log "%ERROR: Failed to delete trusted host 0000.0000.1111." to notify the administrator.
- If you fail to add a trusted host, the system prints the log "%ERROR: Failed to add trusted host 0000.0000.1111." to notify the administrator.
- If the trusted host you want to add already exists, the system prints the log "%ERROR: Trusted host 0000.0000.1111 has already been configured." to notify the administrator.
- If the trusted host you want to delete does not exist, the system prints the log "%ERROR: Trusted host 0000.0000.1111 is not found." to notify the administrator.

Command	**nd-guard trusted-host** *mac*
Parameter Description	*mac*: Indicates the MAC address.
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, you can run the following commands to configure the host to be trusted. This trusted host can send ND packets to the CPU, without any rate limiting or alarm reporting.

Verification

When a network host sends ND attack packets to a switch configured with ND attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets not meeting trusted host configuration exceeds the attack threshold for a port, attack prompt information is displayed.
- If the rate of attack packets meets the trusted host configuration, no prompt information is displayed.

Configuration Example

CPU Protection Based on ND Guard

Scenario	ND host attacks exist in the system, and neighbor discovery fails on some hosts. ND packet traffic of some hosts is very large in the system, and these packets need to pass through.
Configuration Steps	● Configure the host-based attack threshold.

	Ruijie# configure terminal Ruijie(config)# nfpp Ruijie (config-nfpp)# nd-guard rate-limit per-port ns-na 30 Ruijie (config-nfpp)# nd-guard attack-threshold per-port ns-na 50 Ruijie (config-nfpp)#nd-guard trusted-host 0000.0000.1111
Verification	● Run the **show nfpp nd-guard summary** command to display the configurations.
	(Format of column Rate-limit and Attack-threshold is NS-NA/RS/RA-REDIRECT.) Interface Status Rate-limit Attack-threshold Global Disable 30/15/15
	● Run the **show nfpp nd-guard trusted-host** command to display trusted hosts.
	mac ---- 0000.0000.1111 Total: 1 record(s)

4.4.7 Configuring Centralized Rate Limiting and Distribution

Configuration Effect

Configure centralized rate limiting and distribution so that Manage and Protocol packets are first processed when the network is busy.

Notes

The valid percentage range of a type of packets must be equal to or smaller than (100% – percentage of the sum of the other two types).

Configuration Steps

↘ Configuring the Maximum Bandwidth for Each Type of Packets

- (Mandatory) Manage, Route, and Protocol packets share the same default bandwidth. For details, see the *Product Features*.
- Support the global configuration mode on the AC device.

Command	**cpu-protect sub-interface** { **manage** | **protocol** | **route** } **pps** *pps_value*
Parameter Description	**manage**: Specifies Manage packets. **protocol**: Specifies Protocol packets. **route**: Specifies Route packets.

	pps_value: Indicates the rate limit, ranging from 1 to 100,000.
Defaults	For the AC devices, the default attack threshold varies with the product model. For the AP devices, the default rate limit of manage, protocol and route packets is 3,000 pps.
Command Mode	Global configuration mode
Usage Guide	-

Configuring the Maximum Percentage of Each Type of Packets in the Queue

- (Mandatory) By default, Manage packets occupy 30% of the bandwidth, Route packets occupy 25%, and Protocol packets occupy 45%.
- Support the global configuration mode on the AC device.

Command	**cpu-protect sub-interface** { **manage** | **protocol** | **route** } **percent** *percent_value*
Parameter Description	**manage**: Specifies Manage packets. **protocol**: Specifies Protocol packets. **route**: Specifies Route packets. *percent_value*: Indicates the percentage of a type of packets in the queue, ranging from 1 to 100.
Defaults	**manage**: 30% **protocol**: 45% **route**: 25%
Command Mode	Global configuration mode
Usage Guide	The valid percentage range of a type of packets must be equal to or smaller than (100% – percentage of the sum of the other two types).

Configuration Example

Prioritizing Packets Sent to the CPU Through Centralized Distribution

Scenario	● Various types of mass packets exist in the network and belong to different centralized types.
Configuration Steps	● Configure the maximum bandwidth for each type of packets. ● Configure the maximum percentage of each type of packets in the queue.
	`Ruijie# configure terminal` `Ruijie(config)# cpu-protect sub-interface manage pps 5000` `Ruijie(config)# cpu-protect sub-interface manage percent 25`
Verification	Omitted.

4.4.8 Configuring NFPP Log Information

Configuration Effect

NFPP obtains a log from the dedicated log buffer at a certain rate, generates a system message, and clears this log from the dedicated log buffer.

Notes

Logs are continuously printed in the log buffer, even if attacks have stopped.

Configuration Steps

↘ Configuring the Log Buffer Capacity

- Mandatory.
- If the log buffer is full, new logs are discarded and a corresponding prompt is displayed.
- If the log buffer overflows, subsequent logs are discarded and an entry with all attributes marked with a hyphen (-) is displayed in the log buffer. The administrator needs to increase the log buffer capacity or the system message generation rate.
- Support the global configuration mode on the AC device.

Command	**log-buffer entries** *number*
Parameter Description	*number*: Indicates the buffer size in unit of the number of logs, ranging from 0 to 1024.
Defaults	The default buffer size is 256.
Command Mode	NFPP configuration mode
Usage Guide	-

↘ Configuring the System Message Generation Rate

- Mandatory.
- The system message generation rate depends on two parameters: the time segment length and the number of system messages generated in the time segment.
- If both of the preceding two parameters are set to 0, system messages are immediately generated for logs but are not stored in the log buffer.
- Support the global configuration mode on the AC device.

Command	**log-buffer logs** *number_of_message* **interval** *length_in_seconds*
Parameter Description	*number_of_message*: Ranges from 0 to 1,024. The value 0 indicates that all logs are recorded in the log buffer and no system message is generated. *length_in_seconds*: Ranges from 0 to 86,400 (1 day). The value **0** indicates that logs are not recorded in the log buffer but system messages are instantly generated. This also applies to ***number_of_message*** and ***length_in_seconds***.

	number_of_message/length_in_second: Indicates the system message generation rate.
Defaults	The default value of **number_of_message** is 1 and the default value of **length_in_seconds** is 30.
Command Mode	NFPP configuration mode
Usage Guide	

Enabling Log Filtering

- (Optional) Log filtering is disabled by default.
- Logs can be filtered based on a port or VLAN.
- If log filtering is enabled, logs not meeting the filtering rule are discarded.
- Support the global configuration mode on the AC device.

Command	**logging vlan** *vlan-range*
Parameter Description	*vlan-range*: Records logs in a specified VLAN range. The value format is "1-3,5 for example.
Defaults	All logs are recorded by default.
Command Mode	NFPP configuration mode
Usage Guide	Run this command to filter logs so that only logs in the specified VLAN range are recorded. Between port-based log filtering and VLAN-based log filtering, if either rule is met, logs are recorded in the log buffer.

Command	**logging interface** *interface-id*
Parameter Description	*interface-id*: Records logs of a specified port.
Defaults	All logs are recorded by default.
Command Mode	NFPP configuration mode
Usage Guide	Run this command to filter logs so that only logs of the specified port are recorded. Between port-based log filtering and VLAN-based log filtering, if either rule is met, logs are recorded in the log buffer.

Configuration Example

CPU Protection Based on ND Guard

Scenario	● If there are too many attackers, log printing will affect the usage of user interfaces and must be restricted.
Configuration Steps	● Configure the log buffer capacity. ● Configure the system message generation rate. ● Configure VLAN-based log filtering.
	`Ruijie# configure terminal`

	Ruijie(config)# nfpp Ruijie (config-nfpp)#log-buffer entries 1024 Ruijie (config-nfpp)#log-buffer logs 3 interval 5 Ruijie (config-nfpp)#logging interface vlan 1
Verification	● Run the **show nfpp log summary** command to display the configurations.
	Total log buffer size : 1024 Syslog rate : 3 entry per 5 seconds Logging: VLAN 1
	● Run the **show nfpp log buffer** command to display logs in the log buffer.
	Protocol VLAN Interface IP address MAC address Reason Timestamp -------- ---- --------- ---------- ---------- ------ --------- ARP 1 Gi0/5 192.168.206.2 001a.a9c2.4609 SCAN 2013-5-1 5:4:24

4.5 Monitoring

Clearing

Description	Command
Clears the ARP guard scanning table.	**clear nfpp arp-guard scan**
Clears monitored hosts in ARP guard.	**clear nfpp arp-guard hosts**
Clears monitored hosts in IP guard.	**clear nfpp ip-guard hosts**
Clears monitored hosts in IMCP guard.	**clear nfpp icmp-guard hosts**
Clears monitored hosts in DHCP guard.	**clear nfpp dhcp-guard hosts**
Clears monitored hosts in DHCPv6 guard.	**clear nfpp dhcpv6-guard hosts**
Clears logs.	**clear nfpp log**

Displaying

Description	Command
Displays configuration parameters of ARP guard.	**show nfpp arp-guard summary**

Description	Command
Displays monitored hosts of ARP guard.	**show nfpp arp-guard hosts**
Displays the ARP guard scanning table.	**show nfpp arp-guard scan**
Displays trusted hosts in ARP guard.	**show nfpp arp-guard trusted-host**
Displays configuration parameters of IP guard.	**show nfpp ip-guard summary**
Displays monitored hosts in IP guard.	**show nfpp ip-guard hosts**
Displays trusted hosts in IP guard.	**show nfpp ip-guard trusted-host**
Displays configuration parameters of ICMP guard.	**show nfpp icmp-guard summary**
Displays monitored hosts in ICMP guard.	**show nfpp icmp-guard hosts**
Displays trusted hosts in ARP guard.	**show nfpp icmp-guard trusted-host**
Displays configuration parameters of DHCP guard.	**show nfpp dhcp-guard summary**
Displays monitored hosts in DHCP guard.	**show nfpp dhcp-guard hosts**
Displays trusted hosts in DHCP guard.	**show nfpp dhcp-guard trusted-host**
Displays configuration parameters of DHCPv6 guard.	**show nfpp dhcpv6-guard summary**
Displays monitored hosts in DHCPv6 guard.	**show nfpp dhcpv6-guard hosts**
Displays trusted hosts in DHCPv6 guard.	**show nfpp dhcpv6-guard trusted-host**
Displays configuration parameters of ND guard.	**show nfpp nd-guard summary**
Displays trusted hosts in ND guard.	**show nfpp nd-guard trusted-host**
Displays NFPP logs.	**show nfpp log summary**
Displays the NFPP log buffer.	**show nfpp log buffer** [**statistics**]

5 Configuring WAPI

5.1 Overview

WLAN Authentication and Privacy Infrastructure (WAPI) is a wireless network security standard for which China has the proprietary intellectual property rights.

WAPI comprises two parts:

- WLAN Authentication Infrastructure (WAI): a security solution used for identification and key management in a WLAN. WAPI provides two authentication approaches: WAPI pre-shared key authentication and WAPI certificate authentication.
- WLAN Privacy Infrastructure (WPI): a security solution used for data transfer protection in a WLAN, including data encryption, data authentication and replay prevention.

WAPI can be applied in both small- and large-scaled WLANs. The pre-shared key authentication is a simple authentication mechanism not requiring dedicated authentication servers. However, the WAPI certificate authentication needs to use dedicated servers and can be used to provide secure and easy-to-manage access solutions for large-scaled WLANs.

Protocols and Standards

- GB 15629.11-2003/XG1-2006: Information technology - Telecommunications and information exchange between systems - Local and metropolitan area networks - Specific requirements - Part 11: Wireless LAN Medium Access Control (MAC) and Physical Layer (PHY) specifications Amendment 1
- RFC 3280:Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile
- RFC 4492:Elliptic Curve Cryptography (ECC) Cipher Suites for Transport Layer Security (TLS)
- WAPI Multi-trust Certificate Implementation Technology, a technical guide for multi-certificate authentication

5.2 Applications

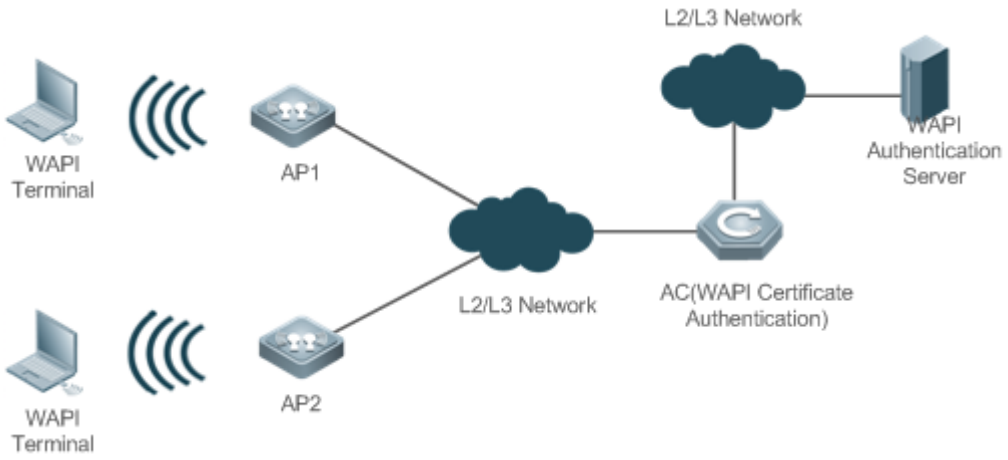
Application	Description
WAPI Certificate Authentication	In large-scaled WLANs, it is recommended to configure the WAPI certificate authentication mode.
WAPI Pre-shared Key Authentication	In small-scaled WLANs or those not requiring management, you can configure the WAPI pre-shared key authentication mode.

5.2.1 WAPI Certificate Authentication

Scenario

In large-scaled WLANs, it is recommended to configure the WAPI certificate authentication mode. Figure 5-1 shows a typical scenario.

Figure 5-1



Deployment

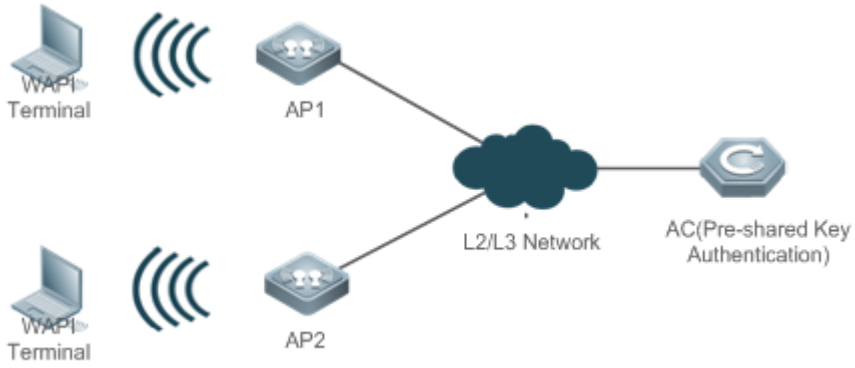
- Configure a WLAN on the AC.
- Configure a server for WAPI certificate authentication.
- Configure the WAPI certificate authentication mode in the WLAN security configuration mode.
- Push the WLAN to the AP.

5.2.2 WAPI Pre-shared Key Authentication

Scenario

In small-scaled WLANs or those not requiring management, you can configure the WAPI pre-shared key authentication mode. Figure 5-2 shows a typical scenario.

Figure 5-2



Deployment

- Configure a WLAN on the AC.
- Configure the PSK certificate authentication approach in the WLAN security configuration mode.

- Push the WLAN to the AP.
- Use this authentication with the WEB authentication to support web-based authentication and charging.

5.3 Features

Basic Concepts

AE

Authenticator Entity: An entity that provides authentication service for the ASUE before the ASUE accesses a service. This entity resides in the AP or AC.

AS

Authentication Server: The AS provides the WAPI certificate authentication service.

ASU

Authentication Service Unit: An entity that provides mutual authentication service for the AE and ASUE. This entity resides in the AS.

ASUE

Authentication Supplicant Entity: An entity that requests authentication before accessing a service. This entity resides in the STA.

BK

Base Key: A key used for exporting unicast session keys. A BK is obtained through negotiation during certificate authentication or is exported from a pre-shared key.

CA

Certification Authority: A CA is a trusted third-party organization who ensures that a certificate is issued to a person who deserves it.

Overview

Feature	Description
WAPI Authentication Approaches	You can enable authentication for an STA that accesses a WLAN.
WAPI Key Management	You can enable unicast key negotiation and multicast key announcement.

5.3.1 WAPI Authentication Approaches

WAPI defines two authentication approaches:

- Certificate authentication
- Pre-shared key authentication

Working Principle

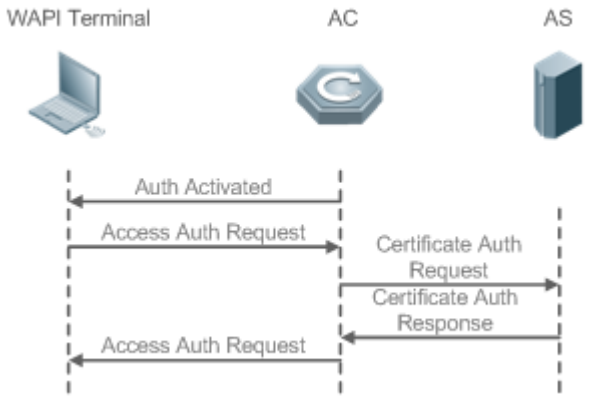
Certificate Authentication

Certificate authentication refers to authentication based on the certificates of an STA and an AE. Before authentication, the STA and AE must have their own certificates. Then, the AS is used to authenticate the STA and AE to generate a BK based on their temporary public keys and private keys and prepare for subsequent unicast key negotiation and multicast key announcement.

When the WAPI function is applied in large-scaled WLANs, the certificate issuing system and certificate authentication system must be separated. The ASUE and AE should be installed with three certificates: user or STA certificate, CA certificate, and trusted ASU certificate. Among them, the ASU certificate is a mandatorily trusted certificate. After the certificates are installed, the ASUE and AE become the CA and ASU. Therefore, we call this mode WAPI three-certificate authentication mode. If the certificate issuing system and certificate authentication system are the same entity, this mode is called WAPI two-certificate authentication mode.

Figure 5-3 shows the certificate authentication process.

Figure 5-3



Remarks	AC is the AE equipment. Auth is short for authentication.

Pre-shared Key Authentication

Pre-shared key authentication refers to authentication based on the keys of an STA and an AE. Before authentication, the STA and AE must be configured with the same key, namely, a pre-shared key. During authentication, the pre-shard key is directly converted into a BK, and then unicast key negotiation and multicast key are announced.

5.3.2 WAPI Key Management

The unicast data between the STA and AE are protected by unicast encryption key and unicast integrity check key obtained through negotiation during the unicast key negotiation. The AE protects sent broadcast/multicast data by using the multicast encryption key and multicast integrity check key announced by itself and exported from the multicast primary key. On the other hand, the STA decrypts received broadcast/multicast data by using the multicast encryption key and multicast integrity check key announced by the AE and exported from the multicast primary key.

Working Principle

Unicast Key Negotiation

Unicast key negotiation is performed first. Figure 5-4 shows the negotiation process.

Figure 5-4

After the certificate authentication succeeds, the AE sends a key negotiation request to the ASUE, containing the key negotiation request data.

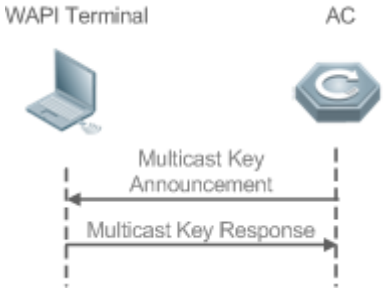
After receiving the unicast key negotiation request and verifying the validity of the request, the ASUE generates key negotiation response data, constructs a unicast key negotiation response and sends the response to the AE. The ASUE and AE generate a unicast session key by using the key negotiation data.

After receiving the unicast key negotiation response and verifying the validity of the response, the AE sends a unicast key negotiation ACK message to the ASUE. In this way, the ASUE and AE establish a unicast key security association.

Multicast Key Announcement

After unicast key negotiation is completed, the key obtained through the unicast key negotiation is used to announce a multicast key. Figure 5-5 shows the announcement process.

Figure 5-5



After the unicast key negotiation succeeds, that is, a unicast key security association is established, the AE sends a multicast key announcement to the ASUE to notify the ASUE of the key used by the AE for sending multicast data.

After verifying the validity of the multicast key announcement sent by the AE, the ASUE sends a multicast key response to the AE. In this way, the ASUE and AE establish a multicast key security association.

In both WAPI certificate authentication and pre-shared key authentication approaches, the key interaction is performed for an STA to access a WLAN.

5.4 Configuration

Configuration	Description and Command	
Configuring WAPI Certificate Authentication	(Mandatory) It is used to enable the WAPI certification authentication approach.	
	security wapi	Configures and enables the WAPI security mode
	security wapi ae cert	Configures the WAPI certificate of the AE equipment
	security wapi asu address	Configures the IP address of the authentication server
	security wapi ca cert	Configures a CA certificate
	(Optional) It is used to enable the WAPI two-certificate or three-certificate authentication mode. After the WAPI certificate authentication mode is enabled, you should specify either the two-certificate or three-certificate authentication mode.	
	security wapi 2-cert	Configures the two-certificate authentication mode
	security wapi 3-cert	Configures the three-certificate authentication mode
	security wapi asu cert	Configures the WAPI certificate for the authentication server
Configuring WAPI Pre-shared Key Authentication	(Mandatory) It is used to enable the WAPI pre-shared key authentication approach.	
	security wapi	Configures and enable the WAPI security mode.
	security wapi psk	Configures and enables the WAPI pre-shared key authentication approach.
	security wapi psk set-key	Configures a WAPI pre-shared key.

5.4.1 Configuring WAPI Certificate Authentication

Configuration Effect

- Enable the WAPI certificate authentication approach and use the certificate authentication approach to authenticate an STA that accesses a WLAN.
- Configure either the two-certificate or three-certificate authentication mode.

Notes

- In the security configuration mode of a WLAN, the two-certificate and three-certificate authentication modes cannot be enabled at the same time.
- The certificate authentication mode must work with the WAPI authentication server.

Configuration Steps

↘ **Enabling the WAPI Security Mode**

- Mandatory.

- It is configured in the WLAN security configuration mode on the AC.

Command	**security wapi** { **enable** | **disable** }
Parameter Description	**enable**: Enables the WAPI security mode. **disable**: Disables the WAPI security mode.
Defaults	Disabled
Command Mode	WLAN security configuration mode
Usage Guide	In the security configuration mode of a WLAN, the WAPI security mode cannot be enabled together with other encryption and authentication modes.

Configuring the Two-Certificate Authentication Mode

- Optional. It is configured when you want to enable the WAPI two-certificate authentication mode. The **security wapi 2-cert { enable | disable }** command can be used to enable or disable the WAPI two-certificate authentication mode.
- It is configured in the WLAN security configuration mode on the AC.
- Before configuring the two-certificate authentication mode, enable the WAPI security mode. In the security configuration mode of a WLAN, the two-certificate and three-certificate authentication modes cannot be enabled at the same time. After the WAPI two-certificate authentication mode is configured, the STA accesses the WLAN by using the two-certificate authentication mode.

Command	**security wapi 2-cert** { **enable** | **disable** }
Parameter Description	**enable**: Enables the WAPI two-certificate authentication. **disable**: Disables the WAPI two-certificate authentication.
Defaults	Disabled
Command Mode	WLAN security configuration mode
Usage Guide	Before configuring the two-certificate authentication mode, enable the WAPI security mode. In the security mode of a WLAN, the two-certificate and three-certificate authentication modes cannot be enabled at the same time.

Configuring the Three-Certificate Authentication Mode

- Optional. It is configured when you want to enable the WAPI three-certificate authentication mode. The **security wapi 3-cert { enable | disable }** command can be used to enable or disable the WAPI three-certificate authentication mode.
- It is configured in the WLAN security configuration mode on the AC.
- Before configuring the three-certificate authentication mode, enable the WAPI security mode. In the security configuration mode of a WLAN, the two-certificate and three-certificate authentication modes cannot be enabled at the same time. After the WAPI three-certificate authentication mode is configured, the STA accesses the WLAN by using the three-certificate authentication mode.

Command	**security wapi 3-cert** { **enable** | **disable** }
Parameter Description	**enable**: Enables the WAPI three-certificate authentication. **disable**: Disables the WAPI three-certificate authentication.

Defaults	Disabled
Command Mode	WLAN security configuration mode
Usage Guide	Before configuring the three-certificate authentication mode, enable the WAPI security mode. In the security configuration mode of a WLAN, the two-certificate and three-certificate authentication modes cannot be enabled at the same time.

Configuring the WAPI Certificate of the AE

- Mandatory.
- It is configured in the WLAN security configuration mode on the AC.

Command	**security wapi ae cert** *ae_certfile*
Parameter Description	*ae_certfile*: Specifies the WAPI certificate file name of the AE
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	Before configuring the AE certificate, enable the WAPI security mode. Before configuration, ensure that the certificate file is imported into the AE and ASUE.

Configuring the IP Address of the Authentication Server

- Mandatory.
- It is configured in the WLAN security configuration mode on the AC.

Command	**security wapi asu address** *ip_address*
Parameter Description	*ip_address*: Specifies the IP address of the authentication server.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	Before configuring the IP address of the authentication server, enable the WAPI security mode.

Configuring the WAPI Certificate for the Authentication Server

- Optional. The ASU certificate must be configured for the three-certificate authentication mode.
- It is configured in the WLAN security configuration mode on the AC.

Command	**security wapi asu cert** *asu_certfile*
Parameter Description	*asu_certfile*: Specifies the ASU certificate file name.
Defaults	N/A
Command Mode	WLAN security configuration mode

Usage Guide	Before configuring the ASU certificate, enable the WAPI security mode. Before configuration, ensure that the certificate file is imported into the AE and ASUE. The ASU certificate must be configured for the three-certificate authentication mode. The ASU certificate does not need to be configured in the two-certificate authentication mode.

Configuring a CA Certificate

- Mandatory.
- It is configured in the WLAN security configuration mode on the AC.

Command	**security wapi ca cert** *ca_certfile*
Parameter Description	*ca _certfile*: Specifies the CA certificate file name.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	Before configuring the CA certificate, enable the WAPI security mode. Before configuration, ensure that the certificate file is imported into the AE and ASUE.

Verification

Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring the WAPI Two-Certificate Authentication Mode for WLAN 1

Scenario **Figure 5-6**	 The IP address of the authentication server is 192.168.1.123.
Configuration Steps	● Enter the security configuration mode of WLAN 1. ● Enable the WAPI security mode. ● Enable the two-certificate authentication mode. ● Configure a CA certificate.

	● Configure the WAPI certificate of the AE. ● Configure the IP address of the authentication server.
AC	`Ruijie(config)#wlansec 1` `Ruijie(config-wlansec)#security wapi enable` `Ruijie(config-wlansec)#security wapi 2-cert enable` `Ruijie(config-wlansec)#security wapi ca cert CA.cer` `Ruijie(config-wlansec)#security wapi ae cert AE.cer` `Ruijie(config-wlansec)#security wapi asu address 192.168.1.123`
Verification	Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	`Ruijie#show running-config | begin wlansec 1` `wlansec 1` `security wapi enable` ` security wapi asu address 192.168.1.123` ` security wapi ca cert CA.cer` ` security wapi ae cert AE.cer` ` security wapi 2-cert enable` `!`

Configuring the WAPI Three-Certificate Authentication Mode for WLAN 1

Scenario **Figure 5-7**	 The IP address of the authentication server is 192.168.1.123.
Configuration Steps	● Enter the security configuration mode of WLAN 1. ● Enable the WAPI security mode. ● Enable the three-certificate authentication mode. ● Configure a CA certificate. ● Configure the WAPI certificate of the AE. ● Configure the WAPI certificate for the authentication server. ● Configure the IP address of the authentication server.

AC	Ruijie(config)#wlansec 1 Ruijie(config-wlansec)#security wapi enable Ruijie(config-wlansec)#security wapi 3-cert enable Ruijie(config-wlansec)#security wapi ca cert CA.cer Ruijie(config-wlansec)#security wapi ae cert AE.cer Ruijie(config-wlansec)#security wapi asu cert ASU.cer Ruijie(config-wlansec)#security wapi asu address 192.168.1.123
Verification	Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	Ruijie#show running-config | begin wlansec 1 wlansec 1 security wapi enable security wapi asu address 192.168.1.123 security wapi asu cert ASU.cer security wapi ca cert CA.cer security wapi ae cert AE.cer security wapi 3-cert enable !

Common Errors

- The WLAN has been enabled with other encryption and authentication modes (such as WEP/RSN/WPA).
- The three-certificate authentication mode is enabled before WAPI security mode.
- The WAPI certificate is not imported into the equipment.

5.4.2 Configuring WAPI Pre-shared Key Authentication

Configuration Effect

- To enable the WAPI pre-shared key authentication, the STA and AE must be configured with the same key in advance.

Notes

- After the WAPI pre-shared key authentication mode is enabled, a pre-shared key must be configured.

Configuration Steps

↘ Enabling the WAPI Security Mode

- Mandatory.
- It is configured in the WLAN security configuration mode on the AC.

Command	**security wapi** { **enable** | **disable** }
Parameter	**enable**: Enables the WAPI security mode.

Description	**disable**: Disables the WAPI security mode.
Defaults	Disabled
Command Mode	WLAN security configuration mode
Usage Guide	In the security configuration mode of a WLAN, the WAPI security mode cannot be enabled together with other encryption and authentication modes.

Enabling the WAPI Pre-shared Key Authentication Approach

- Mandatory. The **security wapi psk { enable | disable }** command can be used to enable or disable the WAPI pre-shared key authentication mode.
- It is configured in the WLAN security configuration mode on the AC .
- Before configuring the WAPI pre-shared key authentication mode, enable the WAPI security mode. The STA can access the WLAN configured with the WAPI pre-shared key authentication only after you input the same pre-shared key as that on the AE.

Command	**security wapi psk** { **enable** | **disable** }
Parameter Description	**enable**: Enables the WAPI pre-shared key authentication mode. **disable**: Disables the WAPI pre-shared key authentication mode.
Defaults	Disabled
Command Mode	WLAN security configuration mode
Usage Guide	Before configuring the WAPI pre-shared key authentication approach, enable the WAPI security mode.

Configuring a WAPI Pre-shared Key

- Mandatory.
- It is configured in the WLAN security configuration mode on the AC.

Command	**security wapi psk set-key** { **ascii** *ascii-key* | **hex** *hex-key* }
Parameter Description	**ascii**: Specifies that the pre-shared key is in the ASCII format. *ascii-key*: Specifies a key consisting of 8-32 ASCII characters. **hex**: Specifies that the pre-shared key is in the hexadecimal format. *hex-key*: Specifies a key consisting of 16-64 hexadecimal characters. The length must be an even number.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	Before configuring the WAPI pre-shared key, enable the WAPI security mode. The key consists of 8-32 ASCII characters.

Verification

Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring the WAPI Pre-shared Key Authentication Approach for WLAN 1 with the Key of 12345678

Scenario **Figure 5-8**	Configuration Steps	● Enter the security configuration mode of WLAN 1. ● Enable the WAPI security mode. ● Enable the WAPI pre-shared key authentication mode. ● Set the WAPI pre-shared key to 12345678.
AC	`Ruijie(config)#wlansec 1` `Ruijie(config-wlansec)#security wapi enable` `Ruijie(config-wlansec)#security wapi psk enable` `Ruijie(config-wlansec)#security wapi psk set-key ascii 12345678`
Verification	Run the **show running-config	begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	`Ruijie#show running-config	begin wlansec 1` `wlansec 1` ` security wapi enable` ` security wapi psk set-key ascii 12345678` ` security wapi psk enable` `!`

Common Errors

- The WLAN has been enabled with other encryption and authentication modes (such as WEP/RSN/WPA).
- The WAPI pre-shared key contains less than 8 or more than 32 ASCII characters.

5.5 Monitoring

Displaying

Description	Command
Displays WAPI user status.	**show wapi-sta summary**

WLAN QoS Configuration

1. Configuring WLAN QoS
2. Configuring WMM
3. Configuring VIP-FIRST

1 Configuring WLAN QoS

1.1 Overview

WLAN QoS (WQoS) is a wireless bandwidth control technology. It involves rate limiting and fair scheduling.

Rate limiting is used to limit the traffic of access points (APs), WLAN, or STAs, thus preventing the traffic from exceeding a specified range. Rate limiting is applicable to scenarios where some STAs occupy too much bandwidth and other STAs do not have sufficient bandwidth.

Fair scheduling, by dividing the time equally, resolves the problem that some nodes occupy the air interfaces for a longer time, particularly low-rate nodes. Fair scheduling is applicable to all wireless networks.

Protocols and Standards

- IEEE 802.11e-2005: Amendment 8: Medium Access Control (MAC) Quality of Service Enhancements, IEEE Computer Society
- Wi-Fi: WMM Specification version 1.1

1.2 Applications

Application	Description
Bandwidth Control in a Fit AP Architecture	A fit AP architecture is deployed with at least one access controller (AC) and one AP.

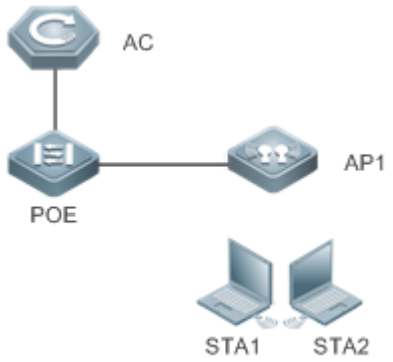
1.2.1 Bandwidth Control in a Fit AP Architecture

Scenario

On the wireless network, an AC is deployed to implement rate limiting on APs, WLANs, and STAs, and fair scheduling on APs.

As shown in Figure 1-1, the AC implements rate limiting on APs, WLANs, and STAs, and fair scheduling on APs.

Figure 1-1



Remarks	AC: Wireless access controller POE: Gateway switch for AP 1 AP 1:Wireless access device STA 1 and STA 2: User devices

Deployment

- Enable WQoS on the AC.

1.3 Features

Basic Concepts

Rate Limiting

To better utilize the limited network resources and serve more users efficiently, the access device need to support rate limiting. When the traffic rate conforms to the committed rates, packets are allowed to pass; otherwise, packets are discarded.

The following parameters are used to evaluate the traffic:

- Average Data Rate: It is the average flow rate that is allowed. It is also called committed information rate (CIR).
- Burst Data Rate: It is the maximum acceptable rate of each burst data, also called committed burst size (CBS).The configured CBS must be greater than the maximum packet length, that is, the maximum rate at which data is sent in a period of 10 milliseconds. (The CBS in the unit of Kbps is equal to the maximum traffic in a period divided by 10 milliseconds).

Fair Scheduling

Fair scheduling allows STAs in the same frequency band of the same AP to share the wireless network resources provided by the AP fairly. The fair scheduling function can prevent low-speed STAs from decreasing the throughput of the entire wireless network, and provide smoother network experience for STAs. Besides, the fair scheduling function provides users with better experience by monitoring changes in the traffic of each STA intelligently and adjusting the proportion of the

wireless bandwidth used by each STA dynamically. In software version later than 10.4(1T19)p1, different priorities can be configured for STAs in fair scheduling so that specified users can preferentially enjoy the wireless bandwidth.

Overview

Feature	Description
Rate Limiting	Limit the rates of an AP, a WLAN, or a STA to that the rate does not exceed the limit.
Fair Scheduling	Associate a STA with other STAs in the same frequency band of the same AP to share the wireless network resources provided by the AP, thus sharing the bandwidth of the wireless network in a fair manner.

1.3.1 Rate Limiting

Rate limiting is used to limit the rates of an AP, a WLAN, or a STA to ensure that the rate does not exceed a certain range.

Working Principle

Rate limiting is implemented based on the token bucket.

- The token bucket records the number of bytes that can pass in a certain period of time.
- In each period, the number of data bytes that can pass is calculated based on the configured CIR and CBS, thereby adjusting the size of the token bucket.
- When a packet arrives, the packet size in bytes is compared with the size of the token bucket. When the packet size is smaller than that of the token bucket, the packet is allowed to pass, and the token bucket size decreases with the corresponding amount. When the packet size is greater than that of the token bucket, two processing methods are followed: the packet is directly dropped. Traffic Policing results in big fluctuation of traffic.
- On an AC, Traffic Policing is used to implement rate limiting of a WLAN.

1.3.2 Fair Scheduling

Fair scheduling, by dividing the time equally, resolves the problem that some nodes occupy the air interfaces for a longer time, particularly low-rate nodes.

Working Principle

Owing to the special characteristics of the wireless network, STAs (including APs) on the same network share the air interface resources, which is also a bottleneck of STA performance. This is one of the differences between the wired and wireless networks. Traditional packet scheduling often adopts the first in first out (FIFO) mode. On one wireless network, every STA that needs to transmit data want to occupy the air interface resources whenever possible. Transmission of overwhelming low-rate packets results in long-time occupation of the air interfaces. Thereby, the lasting queue take-up causes packet loss and degrades the overall performance of the network.

In the real wireless scenarios, STAs often differ in types and performance. Consequently, some STAs always cannot obtain the resources, or get super slow response. What is worse, these STAs cannot access the network, which seriously affects user experience.

To settle the problems, it is essential to ensure that each STA is able to obtain resources on air interfaces fairly. That is, every STA that needs to transmit data can occupy the air interfaces for a fair period of time. Fair scheduling of the wireless links can be achieved by ways as follows: Predict the traffic of every STA based on the STA-specific information (such as negotiated rates and aggregation types) and the valid bytes of packets, convert the traffic to the number of packets that can be transmitted by every STA, and adjust the allowed packet number to allocate the bandwidth to every STA over the air interfaces and implement traffic shaping. With fair scheduling, each STA occupies the air interfaces for an equal period of time, which effectively avoids poor performance of some STAs and thus improves user experience.

1.4 Configuration

Configuration	Description and Command	
Configuring Rate Limiting	(Mandatory) It is used to enable rate limiting.	
	ap-based	Configures AP-based rate limiting on an AC.
	netuser	Configures STA-based rate limiting on an AC.
	wlan-based	Configures WLAN-based rate limiting on an AC.
Configuring Fair Scheduling	(Mandatory) It is used to enable fair scheduling.	
	fair-schedule	Enables fair scheduling.
	(Optional) It is used to adjust the STA priority during fair scheduling.	
	sta-fair	Configures the fair scheduling priority of a STA.

1.4.1 Configuring Rate Limiting

Configuration Effect

- Only the committed resource is allocated to a stream based on the actual situation of the network, which prevents network congestion caused by burst stream.

Notes

- The rate limiting effect of the **wlan-based per-ap-limit** command configured on an AC is equivalent to that of the **wlan-qos wlan-based total-user-limit** command configured on all connected APs.
- The following types of rate limiting are available on STAs: **wlan-based per-user-limit**, **wlan-based per-ap-limit intelligent**, **ap-based per-user-limit**, **ap-based total-limit intelligent**, and **netuser**. However, only one type of them works at a time. From high to low, the priorities of these types of rate limiting are as follows: **netuser**>**wlan-based per-ap-limit intelligent** > **wlan-based per-user-limit** > **ap-based total-limit intelligent** > **ap-based per-user-limit**.
- Rate limiting, including **wlan-based total-limit**, **wlan-based per-ap-limit**, **ap-based total-limit**, and STA-based rate limiting, can take effect on different objects simultaneously without considering priorities.

Configuration Steps

Configuring AP-based Rate Limiting

- Mandatory.
- On an AC, run the **wlan-qos ap-based** command in AP configuration mode to configure AP-based rate limiting.

Command	**wlan-qos ap-based** { **per-user-limit** | **total-user-limit** [**intelligent**] } { **down-streams** | **up-streams** } **average-data-rate** *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	**per-user-limit**: Indicates that rate limiting is implemented on every STA on the AP. **total-user-limit**: Indicates that rate limiting is implemented on all STAs on the AP. **intelligent**: Indicates whether rate limiting is implemented on all STAs on the AP intelligently. **down-streams**: Indicates that rate limiting is implemented on the downlink traffic of the AP. **up-streams**: Indicates that rate limiting is implemented on the uplink traffic of the AP. *average-data-rate*: Indicates CIR. The unit is 8 Kbps. The value ranges from 8 to 261,120. *burst-data-rate*: Indicates CBS. The unit is 8 Kbps. The value ranges from 8 to 261,120.
Defaults	By default, rate limiting is not configured. If **total-user-limit** is configured, intelligent rate limiting is disabled by default.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring STA-based Rate Limiting

- Mandatory.
- On an AC, run the **wlan-qos netuser** command in AC configuration mode to configure STA-based rate limiting.

Command	**wlan-qos netuser** *mac-address* { **inbound** | **outbound** } **average-data-rate** *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	*mac-address*: Indicates the MAC address of a STA. **inbound:** Indicates that rate limiting is implemented on the uplink traffic of a STA. **outbound:** Indicates that rate limiting is implemented on the downlink traffic of a STA. *average-data-rate*: Indicates CIR. The unit is 8 Kbps. The value ranges from 8 to 261,120. *burst-data-rate*: Indicates CBS. The unit is 8 Kbps. The value ranges from 8 to 261,120.
Defaults	By default, rate limiting is not configured.
Command Mode	AC configuration mode
Usage Guide	N/A

Configuring WLAN-based Rate Limiting

- Mandatory.
- On an AC, run the **wlan-based** command in WLAN configuration mode to configure WLAN-based rate limiting.

Command	**wlan-based** { **per-user-limit** | **total-user-limit** [**intelligent**] | **per-ap-limit** } { **down-streams** | **up-streams** }

	average-data-rate *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	**per-user-limit**: Indicates that rate limiting is implemented on every STA on the WLAN. **total-user-limit**: Indicates that rate limiting is implemented on all STAs on the WLAN. **intelligent**: Indicates whether rate limiting is implemented on all STAs on the WLAN intelligently. **per-ap-limit**: Indicates that AP-based rate limiting is implemented. **down-streams**: Indicates that rate limiting is implemented on the downlink traffic of the WLAN. **up-streams**: Indicates that rate limiting is implemented on the uplink traffic of the WLAN. *average-data-rate*: Indicates CIR. The unit is 8 Kbps. The value ranges from 8 to 261,120. *burst-data-rate*: Indicates CBS. The unit is 8 Kbps. The value ranges from 8 to 261,120.
Defaults	By default, rate limiting is not configured.
Command Mode	WLAN configuration mode
Usage Guide	N/A

Verification

- Run the **show dot11 ratelimit ap** command to display the AP-based rate limiting information.
- Run the **show dot11 ratelimit user** command to display the STA-based rate limiting information.
- Run the **show dot11 ratelimit wlan** command to display the WLAN-based rate limiting information.

Configuration Example

Configuring AP-based Rate Limiting

Scenario Figure 1-2	Configuration Steps	● In AP configuration mode, configure AP-based, STA-based, and downlink rate limiting.

AC	Ruijie#configure terminal Ruijie(config)# ap-config ap1 Ruijie(config-ap)#ap-based per-user-limit down-streams average-data-rate 100000 burst-data-rate 120000 Ruijie(config-ap)# exit
Verification	Run the **show dot11 ratelimit ap** command to display the configurations.
AC	AC_20_3F#show dot11 ratelimitap AP name :test, ratelimit info(unit :8kbps): Per-user-limit: Upstream : average rate - 0 , burst rate - 0 Downstream : average rate - 100000, burst rate - 120000 Total-user-limit: Upstream : average rate - 0 , burst rate - 0 Downstream : average rate - 0 , burst rate - 0

1.4.2 Configuring Fair Scheduling

Configuration Effect

- The fair scheduling function can prevent low-speed STAs from decreasing the throughput of the entire wireless network, and provide smoother network experience for STAs.

Notes

- In fit AP mode, configure fair scheduling only on an AC.

Configuration Steps

↘ Enabling Fair Scheduling

- Mandatory.
- On an AC, run the **fair-schedule** command in AP configuration mode to enable fair scheduling.
- Enabling fair scheduling can allocate time to STAs in a fair manner.

Command	**fair-schedule**
Parameter Description	N/A
Defaults	By default, fair scheduling is enabled.
Command Mode	AP configuration mode

Usage Guide	N/A

Configuring the Fair Scheduling Priority

- (Optional) Perform this configuration if you need to change the fair scheduling priority of a STA.
- On an AC, run the **sta-fair** command in AC configuration mode to configure the fair scheduling priority.

Command	**sta-fair** *mac-address* **priority** *priority*
Parameter Description	*mac-address*: Indicates the MAC address of a STA. *priority*: Indicates the priority. The value ranges from 1 to 6.
Defaults	By default, the priority is 1 for all STAs. A greater value indicates a higher priority, and a higher priority indicates that a longer time is allocated to the STA.
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Run the **show ap-config run** command to display the configurations.

Configuration Example

Enabling Fair Scheduling and Configuring the Priority

Scenario Figure 1-3	Configuration Steps	● In AP configuration mode, enable fair scheduling. ● In AC configuration mode, configure the fair scheduling priority of a STA.

AC	Ruijie#configure terminal Ruijie(config)# ap-config ap1 Ruijie(config-ap)#fair-schedule Ruijie(config-ap)# exit Ruijie(config)#ac-controller Ruijie(config-ac)#sta-fair 1111.1111.1111 priority 6 Ruijie(config-ac)# end
Verification	Run the **show ap-config running** and **show running-config** commands to display the configurations.
AC	Ruijie# show ap-config running ! ap-configap1 ! Ruijie# show running-config ! ac-controller sta-fair 1111.1111.1111 priority 6 !

1.5 Monitoring

Displaying

Description	Command
Displays the WQoS rate limiting information.	**show dot11 ratelimit** {**wlan** | **ap** | **user** }

2 Configuring WMM

2.1 Overview

WMM is a wireless QoS protocol, and this protocol is a subset of the 802.11e protocol.

WMM is used to ensure that high-priority packets are preferentially sent, thereby assuring the quality of the voice and video applications in a wireless network.

This document consists of two parts, that is, WMM service and QoS packet priority mapping.

- WMM service: The WMM service is used to differentiate the capabilities of the access channels with different priorities, thereby ensuring that channel resources are allocated based on data flow priorities. Users can adjust the values of the EDCA parameters for the client or AP based on actual requirements to make the AC with a higher priority to start the backoff process earlier than other ACs and preferentially access the channel.
- QoS packet priority mapping: Wireless-to-Wired QoS mapping and wired-to-wireless QoS mapping help to implement end-to-end QoS in the entire network, thereby assuring the quality of high-priority service flows.

Protocols and Standards

- IEEE 802.11e-2005: Amendment 8: Medium Access Control (MAC) Quality of Service Enhancements, IEEE Computer Society
- RFC5416: Control and Provisioning of Wireless Access Points (CAPWAP) Protocol Binding for IEEE802.11

2.2 Applications

Application	Scenario
WMM Service Scenario	Competition process of channels with different priorities.
Wireless-to-Wired Priority Mapping Scenario	Wireless-to-wired QoS packet priority mapping process.
Wired-to-Wireless Priority Mapping Scenario	Wired-to-wireless QoS packet priority mapping process.

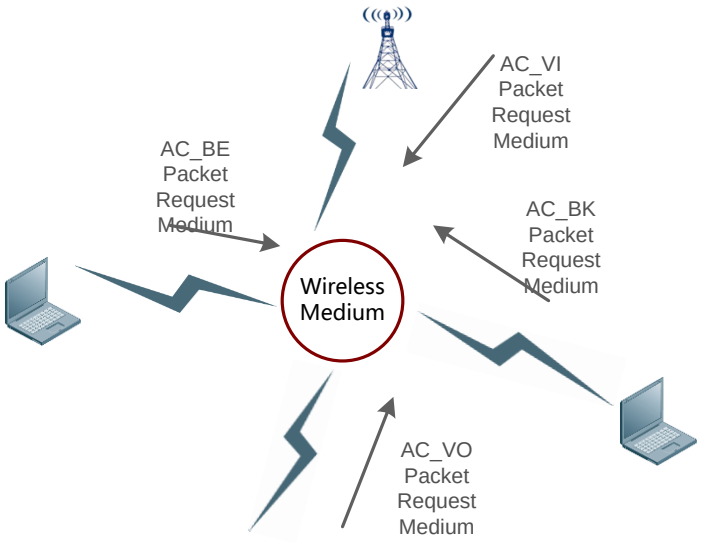
2.2.1 WMM Service

Scenario

The medium for wireless communication is radio. In a specified frequency band, channels are shared during wireless network communication. In the same RF environment, the uplink and downlink traffic of different sites conflicts. Therefore, the problem how communication participants compete for shared channels needs to be solved to ensure wireless QoS. As shown in Figure 2-1, there are packets of four different priorities in the same wireless network environment (the packets from high priority to low are as follows: AC_VO > AC_VI > AC_BE > AC_BK). When multiple supplicants request the medium to

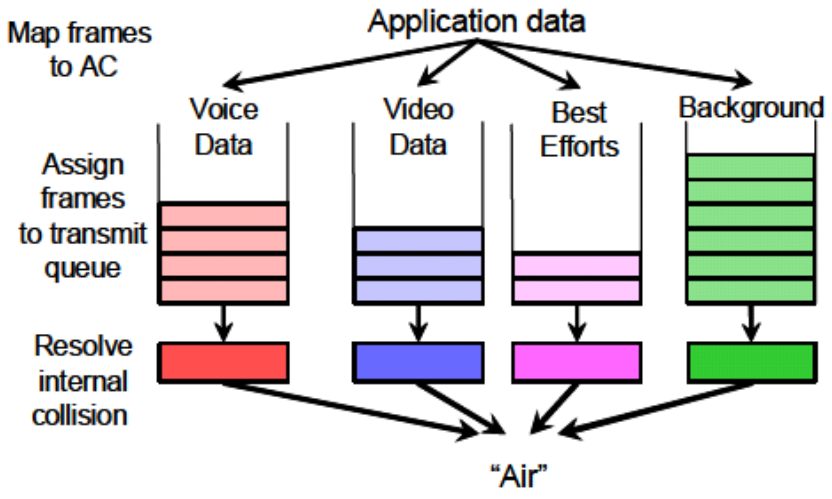
send packets and compete for channels, the competition and coordination mechanism is enabled to determine which supplicant's packet can access the medium. The higher the packet's priority is, the more likely the packet is to access the channel.

Figure 2-1 Channel competition



In a wireless network, since the medium is special, packet damage caused by packet loss and signal interference occurring during transmission over the network is quite serious. Different wireless transmission parameters of the mechanism need to be retransmitted to ensure arrival of packets. However, it is unpractical that preferable parameters are adopted for all packets. In this case, to provide services having high reliability and timeliness requirements, you can classify packets. In short, provide network services of different quality based on various requirements. That is, process key data packets having high timeliness requirement preferentially, and assign a low processing priority to general packets not having high timeliness requirement. To make a network carry different services, you must ensure that the network not only provides single service with the best QoS, but also provides different service with different QoS. Therefore, the QoS of a wireless AP requires the classification/identification of packets for identifying different data flows and providing service of different quality.

Figure 2-2 Wireless QoS multi-priority queue



Deployment

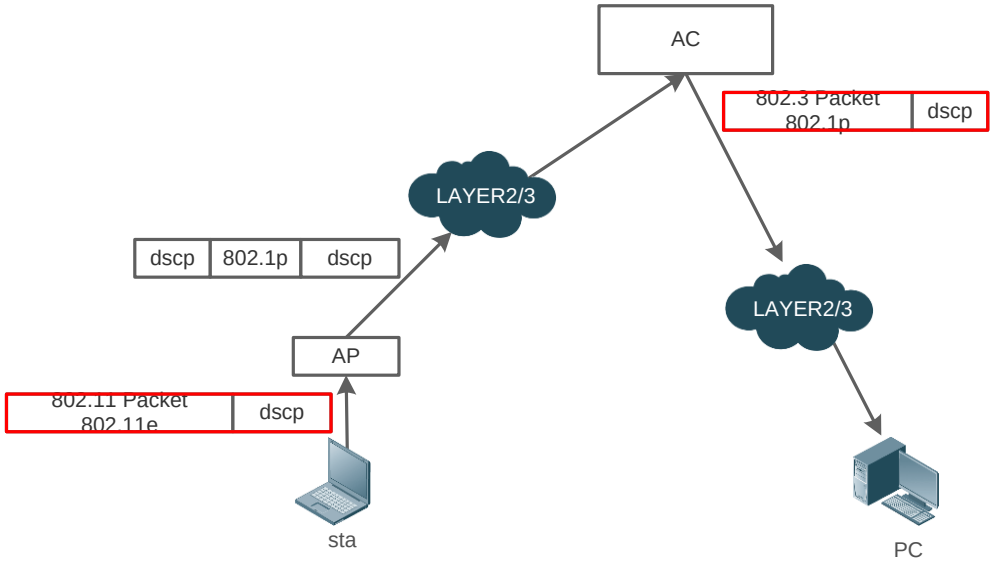
The device should be configured with the following key points:

- Enable the WMM.
- Set WMM EDCA competition parameters. Generally, default values are adopted.

2.2.2 Wireless-to-Wired Priority Mapping

Scenario

Figure 2-3 Wireless-to-wired packet priority mapping



STA-to-PC priority mapping process:

- STA sends an 802.11 packet carrying 802.11e and DSCP information to the AP.

- The AP sets the internal priority of the packet based on the trust mode of the wireless port (configured on the ESS of the AC based on the BSSID). If the trusted packet is with an 802.11e priority, the AP converts the packet with the 802.11e priority into a wired packet with the 802.1p and DSCP priorities and a CAPWAP encapsulated packet with the 802.1p and DSCP priorities. If the trust mode is DSCP priority, the preceding setting shall be performed based on the DSCP priority of the incoming wireless packet. Currently, the default ETH trust mode is DSCP, and the wireless end always maps to the dot11e.
- When passing layer 2/3 network, the CAPWAP packet is processed according to the wired QoS method.
- After receiving the CAPWAP packet, the AC decapsulates the packet and then forwards the wired packet generated after the decapsulation to the layer 2/3 network.
- When passing layer 2/3 network, the wired packet is processed according to the wired QoS method.

Deployment

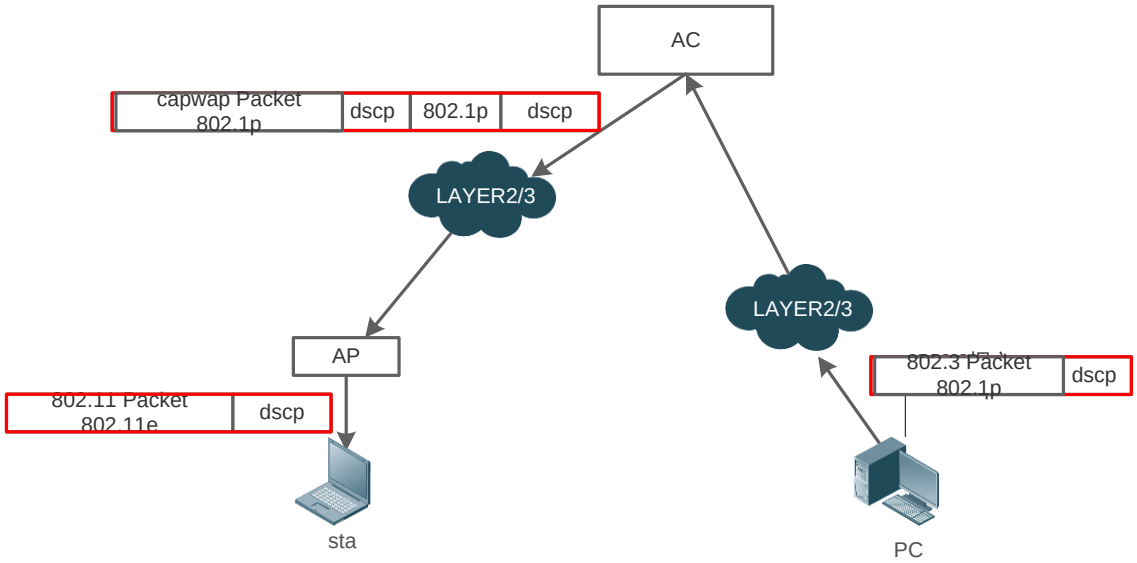
The device should be configured with the following key points:

- Enable the WMM.
- Set the wireless-to-wired priority mapping table. Generally, default values are adopted.

2.2.3 Wired-to-Wireless Priority Mapping

Scenario

Figure 2-4 Wired-to-wireless packet priority mapping



PC-to-station QoS mapping process:

- The AC receives an 802.3Mac packet from the PC.

- Set the internal COS priority of the packet based on the trust mode of the physical port. If the trusted packet has the 802.1p priority and carries tag, set the internal COS priority of the packet based on the 802.1p priority. Otherwise, set the default priority of the packet based on the default priority of the port. If the trust mode is DSCP priority, the preceding setting shall be performed based on the DSCP priority of the incoming wireless packet. Currently, the default ETH trust mode is DSCP, and the wireless end always maps to the dot11e.
- The AC encapsulates the 802.3 packet into a CAPWAP packet.
- After receiving the CAPWAP packet, the AP decapsulates the packet and performs QoS priority mapping for the wired-to-wireless packet generated after decapsulation based on the trust mode of QoS priority. If the trust mode is DSCP, the AP configures 802.11e and DSCP filed of the wireless packet based on the DSCP field value of the 802.3 packet. If the trust mode is 802.1p, the AP performs relevant settings based on the COS field of the 802.3 packet.
- Based on the 802.11e priority of the wireless packet, the AP participates in the competition for wireless channels and sends the wireless packet to the STA.

Deployment

The device should be configured with the following key points:

- Enable the WMM.
- Set the wired-to-wireless priority mapping table. Generally, default values are adopted.

2.3 Features

Basic Concepts

Access Class

According to the WMM standard, access data flows have four priorities. Each priority can be regarded as a class. From the lowest priority to the highest priority, the sequence is as follows: AC_BK, Background <AC_BE, Best Efforts<AC_VI, Video Data <AC_VO, Voice Data.

EDCA Competitive Mechanism

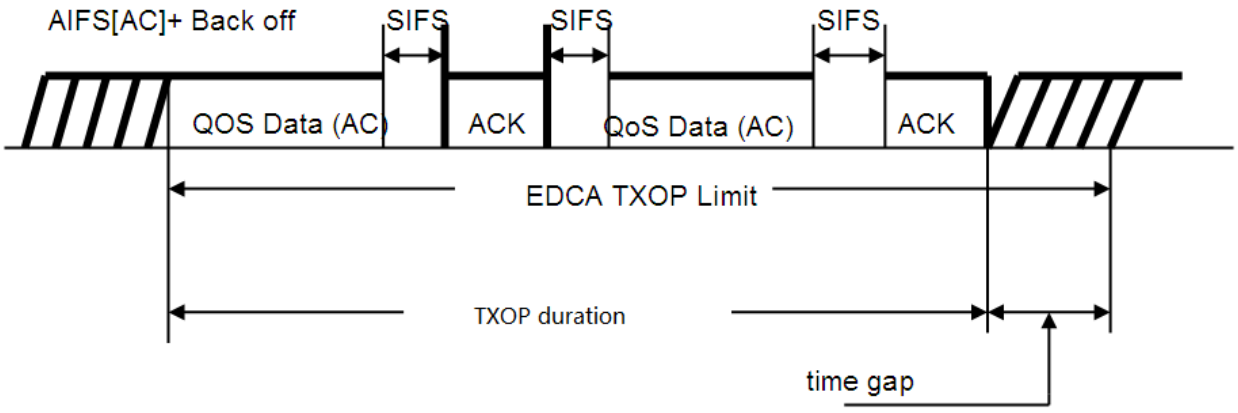
The EDCA competitive mechanism is the core of the IEEE 802.11e. The EDCA differentiates the access capabilities of AC channels with different priorities, ensuring that air interface resources are allocated based on data flow priorities. Enhanced distributed channel access (EDCA) not only retains distributed channel competition between the AP and STA, but also introduces internal competition of four internal priority classes of QAP/QSTA. In this way, EDCA introduces the channel competition mechanism for differentiating the priority classes between different QAPs and QSTAs through the wireless air interface. Competition for channels is implemented by configuring EDCA competition parameters of different priority classes. The QAP pushes the configuration to the QSTA and controls the access capability of the QSTA. Competition parameters include AIFS, TXOP Limit, CWmin, and CWmax.

EDCA Parameters

The EDCA competition parameters are listed as follows:

- AIFSN (Arbitration Inter Frame Spacing Number): In the 802.11 protocol, the Distributed Inter-frame Spacing (DIFS) is a fixed value. However, the DIFS for different ACs of the WMM can be set to different values. A larger AIFSN value means a longer DIFS. A shorter DIFS means a bigger probability of preempting channels.
- ECWmin (Exponent form of CWmin) and ECWmax (Exponent form of CWmax) determine the average backoff time. Larger ECWmin and ECWmax mean a longer backoff time.
- TXOP (Transmission Opportunity): maximum duration for preempting channels after successful competition by a user at one time. A larger TXOP means a longer duration for a user to preempt channels. If the TXOP value is 0, only one packet is sent after channel preemption each time. If a frame is too large to be completely sent within the TXOP, this frame must be segmented.

Figure 2-5 TXOP successive frame transmission



ACK Policy

Two ACK policies are available, that is, Normal ACK and No ACK.

- Normal ACK: After receiving a unicast packet successfully, the recipient returns an ACK response.
- No ACK: In the environment with high communication quality and little interference, you can configure the mechanism of not returning an ACK packet for the flow of a certain priority for confirmation, saving the channel resource. During wireless packet interaction, it is not necessary that an ACK packet is used for confirmation. The No ACK policy helps to improve the transmission efficiency effectively. However, it may cause packet loss.

According to the IEEE 802.11 standard, no ACK is returned for multicast or broadcast frames.

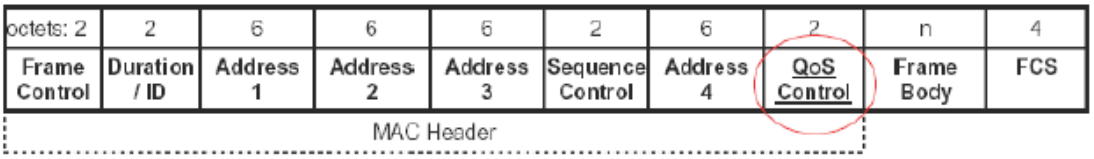
AC Queue Depth

If the queue depth of packets of a certain priority is greater than the preset AC queue depth, subsequent packets are discarded. Otherwise, subsequent packets are added to the queue for processing according to normal logics.

802.11e Priority

802.11e extends the MAC header of 802.11, with the QoS Control domain added, as shown in Figure 2-6.

Figure 2-6 802.11e MAC Header



The QoS Control domain has two bytes. Among them, the first three bits are the TID field, indicating the data form identification code. TID values 0-7 are used for QoS with priorities, indicating the priorities (UP) of users; TID values 8-15 are used for parameter-based QoS, indicating the data flow ID (TSID).

The WMM maps UP to corresponding AC. The following table lists the mapping between the 802.11e priority and AC.

Priority	UP (User Priority)	AC (Access Category)
Lowest ↓ **Highest**	1	Back-ground
	2	Back-ground
	0	Best-effort
	3	Best-effort
	4	Video
	5	Video
	6	Voice
	7	Voice

↘ Priority Mapping Table

After a packet enters a device, the device judges the packet trust mode of the current interface, that is, judges which part of priority information in the received packet is valid. In addition, the device judges the work mode (fat AP or fit AP) of the current AP. Then, the device selects a mapping table based on the preset information to perform the priority mapping operation.

Overview

Feature	Description
WMM Service	Configure WMM service, including EDCA competition parameters, AC queue depth, and ACK policy.
QoS Packet Priority Mapping	Configure QoS packet priority mapping, including the QoS packet priority mapping table and priority mapping policy.

2.3.1 WMM Service

Configure WMM service, including EDCA competition parameters, AC queue depth, and ACK policy.

Working Principle

Provide network services of different quality based on various requirements. That is, provide high-quality services for key data packets having high timeliness requirement and process them preferentially, and assign a low processing priority to

common packets not having high timeliness requirement. According to the WMM standard, access data flows have four priorities. Each priority can be regarded as a class. The EDCA differentiates the access capabilities of AC channels with different priorities, ensuring that air interface resources are allocated based on data flow priorities.

Enabling WMM

Enable/disable the WMM service. When the WMM service is enabled, the four-level priority queue is used for reception and mapping. When the WMM service is disabled, the default priority queue is used for reception and mapping.

EDCA Competitive Mechanism, AC Queue Depth, and NO ACK Policy

- EDCA competitive mechanism:

EDCA parameters differentiate the channel access capabilities of different priorities. Each AC has its own EDCA channel competition parameters. Users can adjust the values of the EDCA parameters on the client or AP based on actual requirements to make the AC with a higher priority to start the backoff process earlier than other ACs and preferentially access the channel. The channel competition should be completed automatically by the hardware. The hardware would be engaged in the channel competition after parameters such as CWmin, CWmax, AIFSN, TXOP of each hardware queue are set on the software.

During actual configuration, you can choose to configure the EDCA parameters on the client side or AP side based on application requirements. The configuration of edca-client mainly affects the wmm competition parameters of sta, and the configuration of edca-radio mainly affects the wmm competition parameters of AP.

The QSTA configuration is managed and pushed by the QAP in a centralized manner. The channel competition parameters of QAP and QSTA are mutually independent. Generally, the channel competition parameters of QAP would be slightly increased to ensure competent channel control capability for QAP. QAP would notify the EDCA parameter setting of QAP through the EDCA Parameter Set IE of the frame of beacon or Probe Response, and push the negotiated EDCA configuration to QSTA through EDCA Parameter Set IE of the (Re)Association Response frame.

- AC queue depth:

Set the AC queue depth. If the queue depth of packets of a certain priority is greater than the preset AC queue depth, subsequent packets are discarded. Otherwise, subsequent packets are added to the queue for processing according to normal logics.

- NO ACK policy:

Enable/disable the NO ACK (No Acknowledgement) policy. The NO ACK policy should be supported by the recipient and the sender at the same time. When the NO ACK policy frame transmission chip does not support NO ACK policy for a queue, the NO ACK policy should be set in the DMA descriptor of each frame sent at each frame sent.

The NO ACK policy is used as an alternative for the method of receiving confirmation (during wireless packet exchange) by using ACK packets in the environment with high communication quality and little interference. The NO ACK policy helps to effectively improve the transmission efficiency. However, if ACK packet for confirmation is not used and the communication quality is poor, the sender would not retransmit the packets even if the recipient has not received the packets, resulting in increasing packet loss rate.

2.3.2 QoS Packet Priority Mapping

Configure QoS packet priority mapping, including the QoS packet priority mapping table and priority mapping policy.

Working Principle

The priority mapping tables provided by the device correspond to relevant priority mapping respectively. Then, a mapping table is selected based on the preset information to perform the priority mapping operation, thereby implementing end-to-end QoS for the entire network.

Packet Priority Mapping

In the IP network, IPv4 packets carry QoS priority tags in three modes, that is, layer 2-based CoS field (IEEE802.1p) priority, IP layer-based IP priority field ToS priority, and IP layer-based DSCP (Differentiated Services Codepoint) field priority.

For the three QoS priority tags of wired packets, it is sufficient to support the two kinds of QoS (DSCP and dot1P) because DSCP is compatible with ToS. In addition to the preceding three modes, the QoS priority tag mode of dot11e is also available for wireless packets.

As for the determination and execution of packet priority mapping, the device judges the packet trust mode or tag policy of the current interface, that is, judges which part of priority information in the received packet is valid. In addition, the device judges the work mode (centralized forwarding or local forwarding) of the current AP. Then, the device selects a mapping table based on the preset information to perform the priority mapping operation.

2.4 Configuration

Configuration	Description and Command	
Configuring the WMM Service	(Mandatory). It is used to enable the WMM service.	
	wmm enable	Enables the WMM service.
	(Optional). It is used to configure competition parameters.	
	wmm edca-client	Configures the EDCA parameters for the client.
	wmm edca-radio	Configures the EDCA parameters for the AP.
Configuring the QoS Packet Priority Mapping	(Optional). It is used to configure the priority mapping. Mapping command for non-interworking versions.	
	wlan-qos map-table	Configures packet priority mapping of the current WLAN.
	(Optional). It is used to configure the 802.11p QoS mapping policy mechanism. Mapping command for interworking versions.	

Configuration	Description and Command	
	wmm dot1p enable	Enables 802.11p QoS mapping policy mechanism.
	wmm dot1p policy 1q	Configures how to apply the 802.11p QoS mapping policy mechanism for the AP.
	wmm dot1p tag	Configures 802.1p priority.
	(Optional) . It is used to configure the DSCP QoS mapping policy mechanism. Mapping command for interworking versions.	
	wmm dscp enable	Enables DSCP QoS mapping policy mechanism.
	wmm dscp policy **outer-tunnel** **inner-tunnel**	Configures how to apply the DSCP QoS mapping policy mechanism for the AP.
	wmm dscp tag	Configures DSCP identifications.

2.4.1 Configuring the WMM Service

Configuration Effect

- Configure the EDCA competition parameters for the client.
- Configure the EDCA competition parameters for the AP.
- Configure the ACK policy.
- Configure the length of the priority queue.

Notes

- The parameter configuration takes effect after the WMM service is enabled.
- When the WMM service is enabled and the BE queue adopts the default configuration, the Xspeed function dynamically adjusts the parameters of the BE queue.

Configuration Steps

Enabling the WMM Service

- Mandatory configuration.
- Run the **wmm enable radio** *radio-id* command in AP configuration mode to enable the WMM for the fit AP.
- When the WMM service is enabled, the four-level priority queue is used for reception and mapping. When the WMM service is disabled, the default priority queue is used for reception and mapping.

Command	**wmm enable radio** *radio-id*
Parameter Description	**radio** *radio-id*: Indicates that radio of the enabled/disabled WMM service is selected. Value range: 1-48.

Defaults	WMM is enabled by default
Command Mode	AP configuration mode
Usage Guide	When the WMM service is disabled, the default priority queue is used for reception and mapping.

Configuring the EDCA Parameters for the Client

- Optional configuration.
- By default, the EDCA parameters on the client side are as follows:

AC	aifs	cwmin	cwmax	txop
back-ground	7	4	10	0
best-effort	3	4	10	0
video	2	3	4	94
voice	2	2	3	47

- After the EDCA parameters on the client side and AC queue depth are set, relevant processing is conducted based on the settings. Otherwise, processing is conducted based on the default settings.

Command	**wmm edca-client** { **back-ground** | **best-effort** | **video** | **voice** } { **aifsn** [*aifsn-value*] **cwmin** [*cwmin-value*] **cwmax** [*cwmax-value*] **txop** [*txop-value*] | **length** [*queue-length*] } **radio** *radio-id*
Parameter Description	**back-ground**: Sets the back-ground queue. **best-effort**: Sets the best-effort queue. **video**: Sets the video queue. **voice**: Sets the voice queue. **aifsn** *aifsn-value*: Sets the aifsn value. Value range: 1-15. **cwmin** *cwmin-value*: Sets the cwmin value. Value range: 0-15. **cwmax** *cwmax-value*: Sets the cwmax value. Value range: 0-15. **txop** *txop-value*: Sets the txop value. Value range: 0-255, unit: 32 μs. **length** *queue-length*: Sets the AC queue length. Value range: 1-255. The default is 255. **radio** *radio-id*: Sets radio of the EDCA parameters on the client. Value range: 1-96. **no**: Restores the default settings.
Command Mode	AP configuration mode
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. The cwmax value must be greater than the cwmin value. Otherwise, a configuration error message is displayed.

Configuring the EDCA Parameters for the AP

- Optional configuration.
- By default, the EDCA parameters on the AP side are as follows:

AC	aifs	cwmin	cwmax	txop

back-ground	7	4	10	0
best-effort	3	4	6	0
video	1	3	4	94
voice	1	2	3	47

- After the EDCA parameters on the AP side and NO ACK policy are set to non-default settings, relevant processing is conducted based on the settings. Otherwise, processing is conducted based on the default settings.
- Smaller AIFS of a high-priority AC means earlier backoff process. Smaller CWmin and CWmax values mean shorter backoff time. TXOP limit allows an AC to transmit multi-frame packets on it continuously within the SIFS interval after preempting a transmission opportunity. A larger TXOP limit means a lower packet conflict rate and a lower waste of air interface resources.

Command	**wmm edca-radio** { **back-ground** | **best-effort** | **video** | **voice** } { **aifsn** [*aifsn-value*] **cwmin** [*cwmin-value*] **cwmax** [*cwmax-value*] **txop** [*txop-value*] | **noack** } **radio** *radio-id*
Parameter Description	**back-ground**: Sets the back-ground queue. **best-effort**: Sets the best-effort queue. **video**: Sets the video queue. **voice**: Sets the voice queue. **aifsn** *aifsn-value*: Sets the aifsn value. Value range: 1-15. **cwmin** *cwmin-value*: Sets the cwmin value. Value range: 0-15. **cwmax** *cwmax-value*: Sets the cwmax value. Value range: 0-15. **txop** *txop-value*: Sets the txop value. Value range: 0-255, unit: 32 μs. **noack**: Indicates that the no ack policy is enabled. The no ack policy is disabled by default. **radio** *radio-id*: Sets radio of the EDCA parameters on the client. Value range: 1-96. **no**: Restores the default settings.
Command Mode	AP configuration mode
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. The cwmax value must be greater than the cwmin value. Otherwise, a configuration error message is displayed.

Verification

- You can run the **show run/show ap-config run** command on the fit AP to display the WMM service status. The EDCA parameters of the client that already take effect and the EDCA parameters used for the AP are not displayed when they adopt default settings.
- Capture packets to display the EDCA parameters of the client.

Configuration Example

Configuring WMM Service Parameters

Configuration Steps	• Enable/disable the WMM service on the AP. • Configure the EDCA parameters for the client.

	• Configure the EDCA parameters for the AP.
	Ruijie # configure terminal Ruijie(config)# ap-config AP001 Ruijie(config-ap)# wmm enable radio 1 Ruijie(config-ap)# wmm edca-client voice aifsn 2 cwmin 2 cwmax 3 txop 50 radio 1 Ruijie(config-ap)# wmm edca-radio voice aifsn 1 cwmin 1 cwmax 3 txop 50 radio 1
Verification	Run the **show run**/**show ap-config run** command on the fit AP to display the EDCA parameters of the client that already take effect and the EDCA parameters used for the AP. These parameters are not displayed when they adopt default settings.

Common Errors

- If no radio exists, an error message is displayed.
- The performance is affected if EDCA parameters are improperly configured. For example, if the value of a low-priority parameter is higher than that of a high-priority parameter, the performance of the high priority is affected.

2.4.2 Configuring the QoS Packet Priority Mapping

Configuration Effect

- Configure packet priority mapping for the current WLAN.
- Configure 802.11p QoS mapping policy mechanism.
- Configure DSCP QoS mapping policy mechanism.

Notes

- QoS packet priority mapping takes effect after the WMM service is enabled.

Configuration Steps

By default, the mapping from DSCP to 802.11e is as follows:

DSCP	802.11e
0-7	0
16-23	1
24-31	2
8-15	3
32-39	4
40-47	5
48-55	6
56-63	7

By default, the mapping from 802.11e to DSCP is as follows:

802.11e	DSCP
0	0
3	8
1	16
2	24
4	32
5	40
6	48
7	56

Configuring Packet Priority Mapping for the Current WLAN

- Optional configuration.
- Unless otherwise specified, packet priority mapping of the current WLAN shall be configured on all APs.

After the priority mapping and the value corresponding to the mapping table are set, relevant processing is conducted based on the settings. Otherwise, processing is conducted based on the default settings.

Command	**wlan-qos map-table** { **dot11e-inner-dscp** | **dot11e-tunnel-dscp** | **dscp-dot11e** } **import** *import-tag-value* **export** *export-tag-value*
Parameter Description	**dot11e-inner-dscp**: Sets priority mapping from dot11e to internal DSCP. **dot11e-tunnel-dscp**: Sets priority mapping from dot11e to CAPWAP DSCP. **dscp-dot11e**: Sets priority mapping from dscp to dot11e. **import** *import-tag-value*: Sets priority of the incoming original packet. **export** *export-tag-value*: Sets priority of the outgoing packet. **no**: Restores the default setting.
Command Mode	WLAN configuration mode
Usage Guide	This command is a mapping command for non-interworking versions. The parameter configuration takes effect only when the WMM service is enabled.

Enabling 802.11p QoS Mapping Policy Mechanism

- Optional configuration.
- Unless otherwise specified, DSCP QoS mapping policy mechanism shall be disabled on all APs.

When the 802.11p QoS policy mechanism is enabled, the mapping table related to 802.11p QoS is used. When the 802.11p QoS policy mechanism is disabled, the default mapping policy is adopted.

Command	**wmm dot1p enable radio** *radio-id*
Parameter	**radio** *radio-id*: Indicates that radio of the enabled/disabled 802.11p QoS mapping policy mechanism is

Description	selected. Value range: 1-96. **no**: Restores the default settings.
Command Mode	AP configuration mode
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled.

Configuring How to Apply the 802.11p QoS Mapping Policy Mechanism for the AP

- Optional configuration.
- Unless otherwise specified, the 802.11p QoS mapping policy mechanism application shall be performed on all APs.

Determine where shall the 802.1Q priority be obtained based on the configuration determining how the AP applies the 802.11p QoS mapping policy mechanism.

Command	**wmm dot1p policy 1q** [*1q-policy-value*] **radio** *radio-id*
Parameter Description	**1q** *1q-policy-value*: Indicates setting for applying the 802.11p QoS mapping policy mechanism. Value range: 0-1. The default is **0**. **radio** *radio-id*: Indicates how the AP applies radio of 802.11p QoS mapping policy mechanism. Value range: 1-96. **no**: Restores the default settings.
Command Mode	AP configuration mode
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. The configuration for applying the 802.11p QoS mapping policy mechanism takes effect only when the 802.11p QoS mechanism is enabled.

Configuring 802.1p Priority

- Optional configuration.
- Unless otherwise specified, 802.1p priority shall be configured on all APs.

Determine the priority of 802.1p based on the configuration of 802.1p priority.

Command	**wmm dot1p tag** [*tag-value*] { **back-ground** | **best-effort** | **video** | **voice** } **radio** *radio-id*
Parameter Description	**tag** *tag-value*: Sets the 802.1p priority. Value range: 0-7. The default **best-effort** is **0**; the default ;**back-ground** is **2**; the default **video** is **4**; the default **voice** is **6**. **back-ground**: Sets the back-ground queue. **best-effort**: Sets the best-effort queue. **video**: Sets the video queue. **voice**: Sets the voice queue. **radio** *radio-id*: Indicates that radio of the enabled/disabled 802.11p QoS mapping policy mechanism is selected. Value range: 1-96. **no**: Restores the default settings.
Command	AP configuration mode

Mode	
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. The 802.1p priority configuration takes effect only when the 802.11p QoS mechanism is enabled.

Enabling DSCP QoS Mapping Policy Mechanism

- Optional configuration.
- Unless otherwise specified, DSCP QoS mapping policy mechanism shall be disabled on all APs.

When the DSCP QoS policy mechanism is enabled, the mapping table related to DSCP QoS is used. When the DSCP QoS policy mechanism is disabled, the default mode is adopted for mapping.

Command	**wmm dscp enable radio** *radio-id*
Parameter Description	**radio** *radio-id*: Indicates that radio of the enabled/disabled DSCP QoS mapping policy mechanism is selected. Value range: 1-96. **no**: Restores the default settings.
Defaults	
Command Mode	AP configuration mode
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled.

Configuring How to Apply the DSCP QoS Mapping Policy Mechanism for the AP

- Optional configuration.
- Unless otherwise specified, the DSCP QoS mapping policy mechanism application shall be performed on all APs.

Determine where shall the DSCP domain priority be obtained based on the configuration determining how the AP applies the DSCP QoS mapping policy mechanism.

Command	**wmm dscp policy outer-tunnel** [*outer-tunnel-value*] **inner-tunnel** [*inner-tunnel-value*] **radio** *radio-id*
Parameter Description	**outer-tunnel** *outer-tunnel-value*: Sets how to apply the DSCP QoS mapping policy mechanism for the outer tunnel header. Value range: 0-1. The default is **0**. **Inner-tunnel** *inner-tunnel-value*: Sets how to apply the DSCP QoS mapping policy mechanism for the inner tunnel header. Value range: 0-1. The default is **0**. **radio** *radio-id*: Indicates how the AP applies radio of DSCP QoS mapping policy mechanism. Value range: 1-96. **no**: Restores the default settings.
Command Mode	AP configuration mode
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. The configuration for applying the DSCP QoS mapping policy mechanism takes effect only when the DSCP QoS mechanism is enabled.

Configuring DSCP Identification

- Optional configuration.
- Unless otherwise specified, DSCP identifications shall be configured on all APs.

Determine the DSCP priority based on the configured DSCP identifications.

Command	**wmm dscp tag** [*tag-value*] { **back-ground** | **best-effort** | **video** | **voice** } **radio** *radio-id*
Parameter Description	**tag** *tag-value*: Sets the DSCP priority. Value range: 0-63. The default **best-effort** is **0**; the default **back-ground** is **16**; the default **video** is **32**; the default **voice** is **48**. **back-ground**: Sets the back-ground queue. **best-effort**: Sets the best-effort queue. **video**: Sets the video queue. **voice**: Sets the voice queue. **radio** *radio-id*: Sets radio of the DSCP identifications. Value range: 1-96. **no**: Restores the default settings.
Command Mode	AP configuration mode
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. DSCP identification configuration takes effect only when the DSCP mechanism is enabled.

Verification

- You can run the **show run**/**show ap-config run** command on the fit AP to display the mapping configuration information. When the default configuration is adopted, no configuration information is displayed in the command output.
- Capture packets to check whether the priority mapping is correct.

Configuration Example

Configuring the QoS Packet Priority Mapping

Scenario		Connect the AC to the L2 switch, and connect AP001 to the AC through the L2 switch. Configure WLAN1 on AP001. Connect STA to AP001 in wireless mode, and connect the PC to the AC in wired mode.

Configuration Steps	Perform the following configuration on the AC: ● Enter the specified WLAN configuration mode. ● Configure the packet priority mapping.
	Ruijie# configure terminal Ruijie(config)# wlan-config 1 Ruijie(config-wlan)#wlan-qos map-table dot11e-tunnel-dscp import 7 export 50 Ruijie(config-wlan)# end
Verification	Import AC_VO priority traffic in the direction from the STA to PC by using IxChariot, capture packets on the air interface, and display the priority at the wireless end. Then, capture packets from the AC to PC using a packet capturing tool to display the priority at the wired end.

Common Errors

- The WMM service is disabled.

2.5 Monitoring

Debugging

⚠ Outputting debugging information consumes system resources. Disable the debugging function immediately after using it.

Command	Function
debug wlan-qos-vsp	Debugs WMM VSP.
debug wlan-qos-cli	Debugs WMM CLI.
debug wlan-qos-map	Debugs WMM mapping.

3 Configuring VIP-FIRST

3.1 Overview

VIP-FIRST is a function used to improve the wireless user experience, which covers preferred access and independent rate limiting for VIP users.

Preferred access for VIP users ensures that VIP users can access the network at any time without being affected by the STA-LIMIT function.

Independent rate limiting for VIP users indicates that an independent rate limit can be configured for VIP users to prevent them being affected by the global rate limit.

3.2 Applications

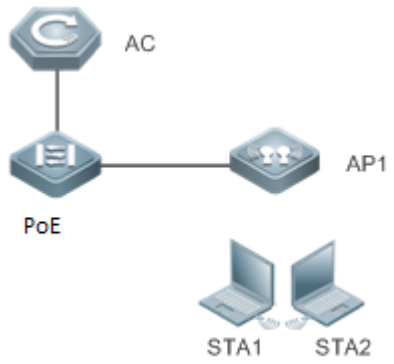
Application	Description
VIP-FIRST in fit AP networking	Fit AP networking is adopted, including at least one AC and one AP.

3.2.1 VIP-FIRST in Fit AP Networking

Scenarios

On the wireless network, an AC is deployed with preferred access and independent rate limit enabled for VIP users. The VIP user list is uploaded to a specific directory on the AC, and the **import** command is run to advertise for the AC to parse the VIP user list, as shown in the following figure.

Figure 3-1



Remarks	AC: wireless access controller PoE: switch, used as the gateway of the AP. AP: wireless access point STA1 and STA2: wireless stations

Deployment

- Enable the VIP-FIRST function on the AC.

3.3 Features

Basic Concepts

Preferred Access for VIP Users

When there are a large number of STAs, the network experience of some STAs may be affected. If the number of STAs connected to the AC, WLAN, AP, or radio exceeds the limit specified by the STA-LIMIT function, preferred access for VIP users ensures that a non-VIP user with poor communication quality is kicked off to ensure that a VIP user can access the network.

Independent Rate Limiting for VIP Users

When there are a large number of STAs, the network experience of some users may be affected. In addition to the global rate limit, an independent rate limit is configured for VIP users to ensure that the bandwidth of VIP users is higher than that of common users.

Overview

Feature	Description
Preferred Access for VIP Users	Ensures that VIP users can access the network at anytime.
Independent Rate Limiting for VIP Users	Ensures that the bandwidth of VIP users is higher than that of common users.

3.3.1 Preferred Access for VIP Users

Preferred access for VIP users ensures that VIP users can access the network anytime without being affected by the STA-LIMIT function.

Working Principle

If the number of STAs connected to the AC, WLAN, AP, or radio exceeds the limit specified by the STA-LIMIT function, a non-VIP user with poor communication quality will be kicked offline to ensure that a VIP user can access the network.

3.3.2 Independent Rate Limiting for VIP Users

In addition to the global rate limit, an independent rate limit is configured for VIP users to ensure that the bandwidth of VIP users is higher than that of common users.

Working Principle

When the global rate limit is configured, a higher independent rate limit is configured for VIP users.

3.4 Configuration

Configuration	Description and Command	
Configuring VIP user parsing or deletion	(Mandatory) It is used to advertise for the AC to parse the VIP user list.	
	vip-first import	Advertises for the AC to parse the VIP user list.
	(Optional) It is used to advertise for the AC to delete the VIP user list.	
	vip-first clear	Clears the VIP user list from the AC.
Configuring Preferred Access for VIP Users	(Mandatory) It is used to enable preferred access for VIP users.	
	vip-first prior-assoc	Enables preferred access for VIP users on the AC.
Configuring Independent Rate Limiting for VIP Users	(Mandatory) It is used to enable independent rate limiting for VIP users.	
	vip-first rate-limit	Configures the uplink and downlink rate limits for VIP users on the AC.

3.4.1 Configuring VIP User Parsing or Deletion

Configuration Effect

- Advertise for the AC to parse or delete the VIP user list.

Notes

- Upload the VIP user list file to the **flash** directory and then run the **import** command to advertise for the AC to parse the VIP user list. It takes several to dozens of seconds for the AC to parse the VIP user list.
- The VIP user list file is named **vip_user_list.txt**.
- The **clear** command will delete VIP users and the VIP user list file cached on the AC.
- The VIP user parsing or deletion command is not saved.

Configuration Steps

Advertising for the AC to Parse the VIP User List

- Mandatory.
- Run the **vip-first import** command in global configuration mode on the AC.

Command	vip-first import
Parameter	N/A

Description	
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show vip-first user [mac]** command to check whether a user is a VIP user.

Advertising for the AC to Delete the VIP User List

- Optional.
- Run the **vip-first clear** command in global configuration mode on the AC.

Command	**vip-first clear**
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **dir** command to check whether the vip_user_list.txt file exists.

Configuration Example

Advertising for the AC to Parse the VIP User List

Scenario Figure 3-2	Configuration Steps	● Advertise for the AC to parse the VIP user list in global configuration mode.
AC	`Ruijie#configure terminal`

	Ruijie(config)# vip-first import Ruijie(config-ap)# exit
Verification	Run the **show vip-first user [mac]** command to display configuration.
AC	AC_20_3F#show vip-first user 0000.0000.0001 STA_MAC YES/NO ------------ ------ 0000.0000.0001 YES

Configuration Example

Deleting the VIP User List

Scenario Figure 3-3	Configuration Steps	● Advertise for the AC to delete the VIP user list in global configuration mode.
AC	Ruijie#configure terminal Ruijie(config)# vip-first clear Ruijie(config-ap)# exit
Verification	Check whether the **vip_user_list.txt** file exists in the **flash** directory.
AC	AC_20_3F# dir Number Properties Size Time Name ------ ---------- ------ ------------------------ -------------------- 1 drwx 160B Tue Apr 25 08:39:38 2017 dev 2 drwx 160B Thu Nov 24 18:06:41 2016 rep 3 drwx 224B Thu Nov 24 18:06:42 2016 var

Common Errors

- The **vip-first import** command is run to advertise for the AC to parse the VIP user list before the **vip_user_list.txt** file is uploaded to the AC.

3.4.2 Configuring Preferred Access for VIP Users

Configuration Effect

- Enable VIP users to access the network anytime without being affected by the STA-LIMIT function.

Notes

- The function can be configured only in global configuration mode on the AC.

Configuration Steps

↘ Enabling Preferred Access for VIP Users

- Mandatory.
- Run the **vip-first prior-assoc** command in global configuration mode on the AC.
- Enable preferred access for VIP users to ensure that VIP users can access the network anytime without being affected by the STA-LIMIT function.

Command	**vip-first prior-assoc**
Parameter Description	N/A
Defaults	Preferred access for VIP users is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running-config** command to display configuration.

Configuration Example

↘ Enabling Preferred Access for VIP Users

Scenario **Figure 3-4**	Configuration Steps	● Enable preferred access for VIP users in global configuration mode on the AC.
AC	`Ruijie#configure terminal` `Ruijie(config)# vip-first prior-assoc` `Ruijie(config-ap)# exit`
Verification	Run the **show running-config** command to display configuration.
AC	`Ruijie# show ap-config running` `!` `vip-first prior-assoc!`

3.4.3 Configuring Independent Rate Limiting for VIP Users

Configuration Effect

- Ensure that the bandwidth of VIP users is higher than that of common users.

Notes

- An independent rate limit can be configured for VIP users only after a global rate limit is configured, and the VIP user rate limit must be greater than the global rate limit. The global rate limit takes effect to all STAs under the AC.

Configuration Steps

↘ Enabling Independent Rate Limiting for VIP Users

- Mandatory.
- Global configuration mode
- Enable independent rate limiting for VIP users to increase the bandwidth of VIP users.

Command	**vip-first rate-limit** { **down-stream** | **up-stream** } **average-rate** *average-rate* **burst-rate** *burst-rate*
Parameter	**down-streams**: Sets the downlink rate limit of an AP.

Description	**up-streams**: Sets the uplink rate limit of an AP. *average-rate*: Sets the average rate limit by a step of 8 kbit/s. The value range is **8** to **261120**. *burst-rate*: Sets the burst rate limit by a step of 8 kbit/s. The value range is **8** to **261120**.
Defaults	Independent rate limiting for VIP users is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running-config** command to display configuration.

Configuration Example

Enabling Independent Rate Limiting for VIP Users

Scenario Figure 3-5	Configuration Steps	● Enable independent rate limiting for VIP users in global configuration mode on the AC.
AC	`Ruijie#configure terminal` `Ruijie(config)# vip-first rate-limit up-stream average-rate 8 burst-rate 8` `Ruijie(config)# vip-first rate-limit down-stream average-rate 8 burst-rate 8` `Ruijie(config-ap)#end`
Verification	Run the **show ap-config running** command to display configuration.
AC	`Ruijie# showap-config running` `!` `vip-first rate-limit up-stream average-rate 8 burst-rate 8` `vip-first rate-limit down-stream average-rate 8 burst-rate 8` `!`

3.5 Monitoring

Displaying

Description	Command
Checks whether a user is a VIP user.	**show vip-first user [mac]**

WLAN Networking Configuration

1. Configuring WLAN Hot Backup
2. Configuring WDS
3. Configuring RIPT
4. Configuring Virtual AC
5. Configuring Bonjour Gateway

1 Configuring WLAN Hot Backup

1.1 Overview

Wireless LAN (LAN) hot backup is a wireless dual-host hot backup function.

The WLAN hot backup function enables switchover of the Control and Provisioning of Wireless Access Points (CAPWAP) tunnels between access controllers (ACs) and access points (APs) within several milliseconds when an AC is unreachable or faulty, thus ensuring uninterrupted services for associated stations (STAs) to the maximum extent.

Working modes of WLAN hot backup include the Active/Standby (A/S) mode and the Active/Active (A/A) mode.

WLAN hot backup is applicable to a reliability-sensitive wireless network.

Protocols and Standards

- N/A

1.2 Applications

Application	Description
1+1 A/S Networking	Two ACs are deployed. AC-1 and AC-2 are configured as hot backup ACs working in A/S mode.
1+1 A/A Networking	Two ACs are deployed. AC-1 and AC-2 are configured as hot backup ACs working in A/A mode.
N+1 A/S Networking	N+1 ACs are deployed and configured as hot backup ACs working in A/S mode.
Hierarchical AC Networking	A special N+1 networking mode, which is adopted in hierarchical AC scenarios.

1.2.1 1+1 A/S Networking

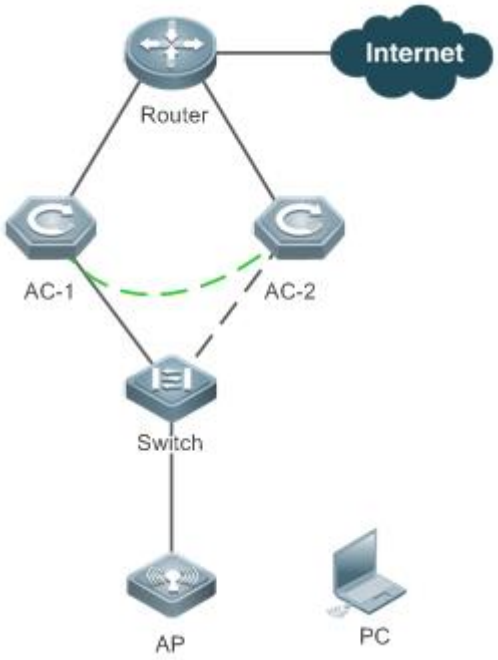
Scenario

On a wireless network, two ACs are deployed. One AC works as the active AC and provides services to external entities. The other AC works as the standby AC and receives data synchronized from the active AC.

When the active AC is unreachable due to some reasons (for example, because the AC is upgraded and restarted or the power supply of the equipment room is interrupted), the standby AC can take over services from the active AC to ensure that the wireless network is not affected.

As shown in Figure 1-1, when AC-1 is unreachable but the switch and other devices work normally, AC-2 takes over services from AC-1. The wireless network is not affected and can still provide wireless services normally.

Figure 1-1



Remarks	Router is a routing device that functions as the gateway of STAs. AC-1 and AC-2 are wireless access controllers. Switch is a convergence device that functions as the gateway of APs. AP is a wireless access device. PC is a user device that functions as a STA.

Deployment

- Enable the WLAN hot backup function on AC-1 and AC-2, and configure a hot backup context.
- Add the AP group to which the AP belongs to the WLAN hot backup context.

1.2.2 1+1 A/A Networking

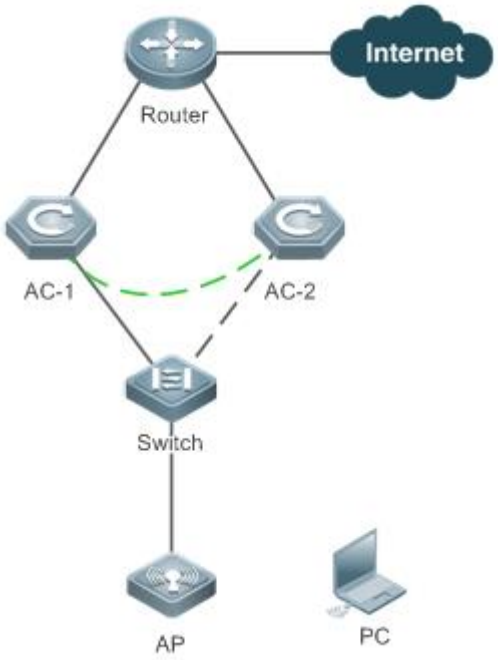
Scenario

On a wireless network, two ACs are deployed. Both ACs work as the active ACs and provide services to external entities. Both ACs work as the standby AC of the peer AC and receive data synchronized from the peer AC.

When one AC is unreachable due to some reasons (for example, because the AC is upgraded and restarted or the power supply of the equipment room is interrupted), the other AC can take over services from the unreachable AC to ensure that the wireless network is not affected.

As shown in Figure 1-2, when AC-1 is unreachable but the switch and other devices work normally, AC-2 takes over services from AC-1. The wireless network is not affected and can still provide wireless services normally.

Figure 1-2



Remarks	Router is a routing device that functions as the gateway of STAs. AC-1 and AC-2 are wireless access controllers. Switch is a convergence device that functions as the gateway of APs. AP is a wireless access device. PC is a user device that functions as a STA.

Deployment

- Enable the WLAN hot backup function on AC-1 and AC-2, and configure two hot backup contexts.
- Add the AP group to which the AP belongs evenly to the two WLAN hot backup contexts.

1.2.3 N+1 A/S Networking

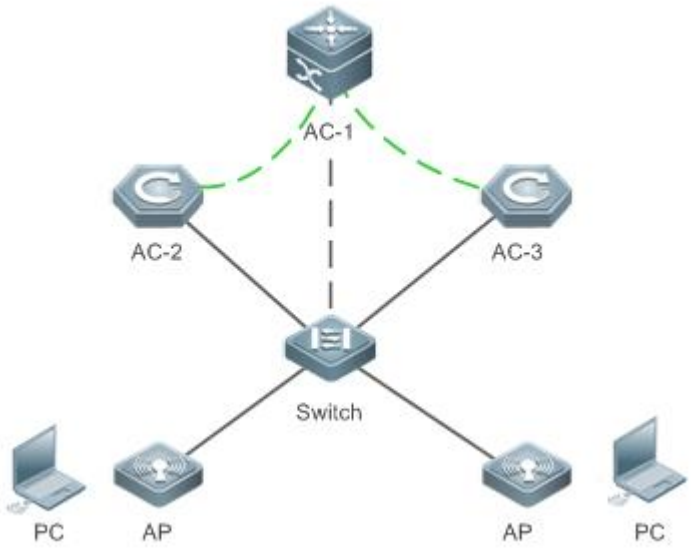
Scenario

On the wireless network, N+1 ACs are deployed. *N* ACs work as the active ACs and provide services to external entities. The other AC works as the standby AC and receives data synchronized from the active ACs.

When one active AC is unreachable (for example, when the AC is upgraded and restarted or the power supply of the equipment room is interrupted), the standby AC can take over services from the active AC to ensure that the wireless network is not affected.

As shown in Figure 1-3, when AC-2 is unreachable but the switch, APs, and other devices work normally, AC-1 takes over services from AC-2. The wireless network is not affected and can still provide wireless services normally.

Figure 1-3



Remarks	Router is a routing device that functions as the gateway of STAs. AC-1, AC-2, and AC-3 are the wireless access controllers. Switch is a convergence device that functions as the gateway of APs. AP is a wireless access device. PC is a user device that functions as a STA.

The N+1 A/S networking mode is not compatible with the 1+1 A/A networking mode.

Deployment

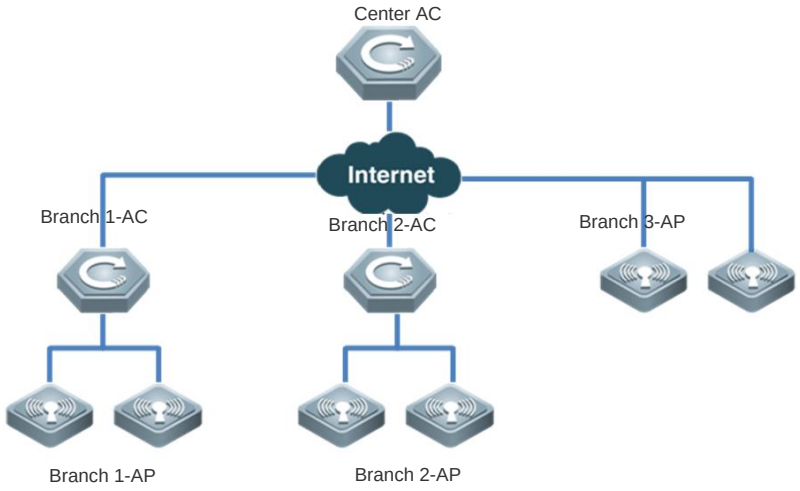
- Enable the WLAN hot backup function on AC-1, and configure two hot backup contexts. Enable the WLAN hot backup function on AC-2 and AC-3, and configure a hot backup context respectively on AC-2 and AC-3.
- Add the AP group to which the AP belongs to the WLAN hot backup context.

1.2.4 Hierarchical AC Networking

Scenario

Hierarchical AC is a centralized management and distributed forwarding model. In this model, ACs are classified into the center AC and branch ACs. A high-performance AC is deployed at the center, and low-end ACs are deployed at braches. The following figure shows the model.

Figure 1-1



Deployment

- Enable the WLAN hot backup function and configure two hot backup instances on the center AC. Enable the WLAN hot backup function and configure one hot backup instance on Branch 1-AC and Branch 2-AC.
- Configure hierarchical AC roles on the center AC, Branch-1 AC, and Branch-2 AC.
- Add the AP groups to which the APs belong to the corresponding WLAN hot backup instances.

1.3 Features

Basic Concepts

AC Keepalive Channel

After the hot backup function is enabled, the active AC periodically sends a keepalive packet to the standby AC, and the standby AC determines whether the active AC works normally based on the received keepalive packet. If the standby AC does not receive the packet in5 consecutive keepalive periods, the standby AC determines that the active AC is faulty, and then notifies APs to activate the standby CAPWAP tunnels.

The keepalive period between ACs is 10s by default and is configurable.

Active CAPWAP Tunnel

To support the hot backup function, an AP must set up CAPWAP tunnels with two ACs that are configured with the hot backup relationship. The CAPWAP tunnel between the AP and the active AC is activated, and is called active CAPWAP tunnel.

Standby CAPWAP Tunnel

The CAPWAP tunnel between an AP and the standby AC is called standby CAPWAP tunnel. The standby CAPWAP tunnel is not used for communication between the AP and the AC.

Hot Backup Context

In A/A mode, the role taken by the same AC varies according to APs. An AC that sets up an active CAPWAP tunnel with an AP serves as the active AC of the AP. An AC that sets up an standby CAPWAP tunnel with an AP serves as the standby AC of the AP. The AC must perform different backup operations when taking different roles. Therefore, on the same AC, different hot backup contexts must be configured so that the AC can perform different backup operations.

Overview

Feature	Description
Configuring the Hot Backup Function	Enable the hot backup function to synchronize the data.

1.3.1 Configuring Hot Backup

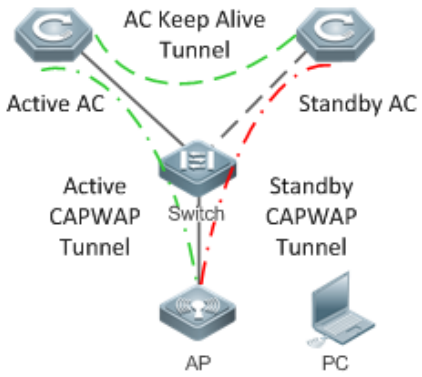
Configure the addresses of hot backup neighbors and contexts, and bind the AP groups, DHCP address pool, and VRRP groups with the corresponding contexts so that the hot backup function is enabled on the AP groups, DHCP address pool, and VRRP groups to support data synchronization and switchover.

Working Principle

The WLAN hot backup detection packet is a UDP packet, and the port ID is 7425. The control channel packet is a TCP packet, and the port ID is 6435. The data channel packet is a TCP packet, and the port ID is 6425. The heartbeat keepalive packet is an IP packet by default and can be configured as the UDP packet, the protocol field is 0, and the port ID is 7435.

WLAN hot backup enables switchover of the CAPWAP tunnels between ACs and APs within several milliseconds when an AC is unreachable or faulty, thus ensuring uninterrupted services for associated STAs to the maximum extent. Figure 1-4 shows the working principle of the WLAN hot backup function.

Figure 1-4 WLAN hot backup



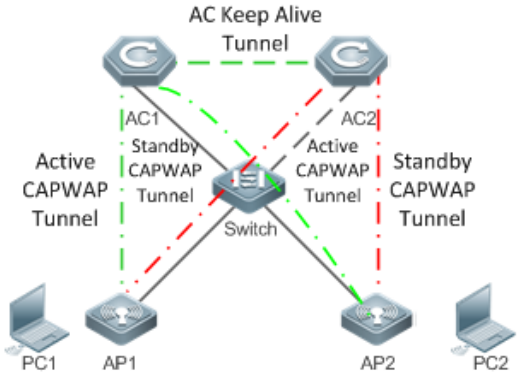
- Two ACs determine the active and standby ACs through negotiation, and the keepalive mechanism is used between ACs.
- The AP sets up an active CAPWAP tunnel with the active AC, and a standby CAPWAP tunnel with the standby AC.

- The user uses a wireless client to associate with the AP.
- The user communicates with entities on the network through the active CAPWAP tunnel.
- When the active AC is faulty, the standby AC detects the keepalive timeout event, and immediately notifies the AP.
- The standby CAPWAP tunnel is activated, and the standby AC becomes the active AC.
- The user's services are recovered after the standby CAPWAP tunnel is activated.
- When the original active AC is recovered, it sets up a hot backup relationship with the new active AC again. Then, the original active AC becomes the standby AC and sets up a standby CAPWAP tunnel with the AP. In this way, the user's services are not interrupted.

Working modes of WLAN hot backup include the A/S mode and the A/A mode.

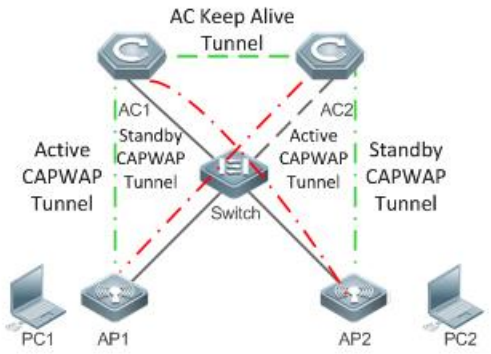
In A/S mode, one AC is the active AC, and the other AC is the standby AC. The active AC processes all services and transfers the service status information to the standby AC for backup purpose. The standby AC does not process services, and only backs up the service data. In A/S mode, all the APs set up active CAPWAP tunnels with the active AC, and standby CAPWAP tunnels with the standby AC. When both ACs work normally, all services are processed by the active AC. When the active AC is faulty, the standby AC takes over all services.

Figure 1-5 WLAN hot backup in A/S mode



In A/A mode, both ACs are active ACs and process services, and meanwhile serve as the standby AC of the other AC and back up the service status information of the other AC. Assume that the two ACs are AC1 and AC2. In A/A mode, some APs set up active CAPWAP tunnels with AC1, and standby CAPWAP tunnels with AC2. Other APs set up active CAPWAP tunnels with AC2, and standby CAPWAP tunnels with AC1. When both ACs work normally, the two ACs process services of APs with which active CAPWAP tunnels are set up. When AC1 is faulty, APs that set up active CAPWAP tunnels with AC1 switch over services to standby CAPWAP tunnels, and then AC2 processes services of all APs.

Figure 1-6 WLAN hot backup in A/A mode



1.3.2 Configuring Hierarchical AC

Working Principle

Hierarchical AC is a special N+1 networking mode. In normal cases, the center AC is a high-performance AC and deployed at the center and branch ACs are deployed at branches. Hierarchical AC ensures unified upgrade, disaster recovery, unified management, and license sharing.

In hierarchical AC scenarios, a new work mode, cold is added, which indicates lightweight data backup. In cold mode, most data backup with the peer is forbidden and only little data transmission is reserved. When traffic of the center AC is heavy, configure the work mode as cold to reduce the load of the center AC. In cold mode, when a branch AC is faulty, STAs need to be re-associated and STAs' IP addresses need to be obtained again for authentication. In cold mode, the unified upgrade, unified management, and license sharing functions are reserved.

1.4 Configuration

Configuration	Description and Command	
Configuring Hot Backup	(Mandatory) It is used to enable the hot backup function.	
	wlan hot-backup	Configures a hot backup neighbor.
	context	Configures a hot backup context.
	wlan hot-backup enable	Enables the hot backup function.
	(Optional) It is used to adjust the hot backup connection parameters.	
	local-ip	Configures the IP address of the local AC for the hot backup function.
	work-mode	Configures the hot backup working mode.
	hello-interval	Configures the heartbeat keepalive period for the hot backup function.

	kplv-pkt	Configures the format of the heartbeat keepalive packet for hot backup.
	priority level	Configures the priorities of contexts.
	ap-group	Binds an AP group with a context.
	dhcp-pool	Binds a DHCP address pool with a context.
	dhcpv6-pool	Binds a DHCPv6 address pool with a context.
	vrrp interface group	Binds a VRRP group with a context.
	description	Describes the hot backup peer.
Configuring Hierarchical AC	⚠ (Mandatory) It is used to enable the hierarchical AC function.	
	wlan hot-backup [center | branch]	**wlan hot-backup [center | branch]**
	⚠ (Optional) It is used to set the lightweight backup mode.	
	work-mode cold	**work-mode cold**

1.4.1 Configuring the Hot Backup Function

Configuration Effect

- Configure a hot backup connection to provide the hot backup service for other modules.

Notes

- After the hot backup function is enabled, the hot backup related configurations cannot be modified.

Configuration Steps

↘ Configuring the Basic Information about Hot Backup

- (Mandatory) The configuration is performed on the AC.
- Run the **wlan hot-backup** command to configure a hot backup neighbor. Unless otherwise specified, you must configure a hot backup neighbor on both ACs. Enter the hot backup configuration mode, and configure the working mode and context for the hot backup function.
- In the hot backup configurations, the peer IP address is the loopback IP address of the peer AC. Ensure that the loopback IP address has been correctly configured; otherwise, hot backup may fail. In addition, configure the related routes to ensure that the local and peer loopback IP addresses can be pinged successfully from each other.
- Run the **context** command to configure a context. Unless otherwise specified, you must configure the same context on both ACs.

Command	**wlan hot-backup** *ip-address*
Parameter Description	*ip-address*: indicates the IP address of the peer AC.
Defaults	No hot backup neighbor is configured.
Command	Global configuration mode

Mode	
Usage Guide	N/A

Command	**context** *context-id*
Parameter Description	*context-id*: indicates the ID of the context.
Defaults	N/A
Command Mode	Hot backup configuration mode
Usage Guide	The value range is 0 to 65,535. In hierarchical AC scenarios, the value is 0-0.

Adjusting the Hot Backup Parameters

- (Optional) The configuration is performed on the AC.
- Run the **local-ip** command to configure the IP address of the local AC for hot backup. By default, the IP address of the Loopback 0 interface on the AC is used. You can configure another IP address of the AC for setting up a hot backup relationship with the peer AC.
- Run the **work-mode** command to configure the hot backup working mode. Hot backup is switched to the quick switchover mode only in an environment that requires quick switchover, for example, in the onsite test environment. Two hot backup working modes are available: (1) Quick switchover mode: It is used in performance switchover scenarios that require sensitive detection and quick switchover, such as system demonstration and performance test. The purpose is to realize quick switchover. The default detection period is 10 ms. (2) Normal switchover mode: It is used in real-life application scenarios that require stable running and avoid hot backup flapping. The purpose is to realize normal running of the network. The default detection period is 2s.
- Run the **hello-interval** command to configure the heartbeat keepalive period for the hot backup function. If quick switchover is required, you can set this parameter to a smaller value to increase the speed of hot backup detection and switchover. A smaller value of **hello-interval** indicates that a disconnection can be detected faster and it is easier to trigger a switchover. A larger value of **hello-interval** indicates that the hot backup relationship is more stable.
- Run the **kplv-pkt** command to configure the format of the heartbeat keepalive packet. If the NAT deployed between ACs, IP packets are not allowed to be routed to the NAT device due to the restriction of the intermediate NAT device. You can run this command to change the format of the heartbeat keepalive packet to the UDP packet to ensure that the heartbeat channel is set up for hot backup.
- Run the **priority level** command to configure the priority of a context. If an AC must be preferentially selected as the active AC, the hot backup priority of this AC must be increased. If an AC is required to support the switchback function, the hot backup priority of this AC must be set to 7.
- If the priority of an AC is high, the AC will be preferentially selected as the active AC when the hot backup connection is set up for the first time. If the AC with the priority set to 7 is selected as the standby AC and completes batch backup of data, a hot backup switchback will be performed and this AC will be changed to the active AC again. A precondition for hot backup switchback is that all APs that are connected with the peer AC also set up connections with the local AC. If the precondition is met and the AC with the priority set to 7 is selected as the standby AC, a hot backup switchback will

be performed within the minimum switchover time (configurable, 10 min by default) after batch backup is completed. Otherwise, a switchback will be performed forcibly 45 minutes after batch backup is completed. Some STAs may go offline due to the forced switchback.

Command	**local-ip** *ip-address*
Parameter Description	*ip-address*: indicates the IP address of the local AC.
Defaults	The IP address of the Loopback 0 interface is used by default.
Command Mode	Hot backup configuration mode
Usage Guide	When the IP address of the local AC changes, the hot backup connection will be interrupted, and then the new IP address of the local AC will be used to set up a hot backup connection.

Command	**work-mode** [**normal** | **quick-switch | cold**]
Parameter Description	**normal**: indicates the normal switchover mode. **quick-switch**: indicates the quick switchover mode.
Defaults	normal
Command Mode	Hot backup configuration mode
Usage Guide	N/A

Command	**hello-interval** *hellointerval*
Parameter Description	*hellointerval*: indicates the heartbeat keepalive period. The unit is ms. The value ranges from 10 to 600,000.
Defaults	The default value is related to the current work mode. When the work mode is normal, the default value is 2s (2000 ms). When the work mode is quick-switch, the default value is 10 ms. After the hierarchical AC function is configured, the default value is 30s (30,000 ms).
Command Mode	Hot backup configuration mode
Usage Guide	The value range is 10 to 600,000. In hierarchical AC scenarios, the value range is 30,000 to 600,000.

Command	**kplv-pkt** [**ip** | **udp**]
Parameter Description	**ip**: indicates that the heartbeat keepalive packet is an IP packet. **udp**: indicates that the heartbeat keepalive packet is a UDP packet.
Defaults	IP packet
Command Mode	Hot backup configuration mode
Usage Guide	N/A

Command	**description** *name*
Parameter Description	*name*: Indicates the name of the hot backup peer.
Defaults	No name is configured.
Command Mode	Hot backup configuration mode
Usage Guide	N/A

Command	**priority level** *priority*
Parameter Description	*priority*: indicates the hot backup priority.
Defaults	The hot backup priority is 4 by default. In hierarchical AC scenarios, the hot backup priority is 7 for a branch AC.
Command Mode	Hot backup context mode
Usage Guide	The priority ranges from 0 to 7. The default priority is 4, and the highest priority is 7. In hierarchical AC scenarios, the hot backup priority is 7 for a branch AC.

Binding the Hot Backup Function with a Context

- (Optional) The configuration is performed on the AC.
- Run the **ap-group** command to bind an AP group with a hot backup context. After the AP group is bound with the hot backup context, data of STAs associated with APs in the AP group can be synchronized from the active AC to the standby AC.
- Run the **dhcp-pool** command to bind a DHCP address pool with a hot backup context. If the IP addresses of STAs are on the hot backup AC, you need to bind the DHCP address pool to realize synchronization of DHCP entries between the active and standby ACs. After the DHCP address pool is bound with the context, allocated IP addresses in this DHCP address pool can be synchronized from the active AC to the standby AC.
- Run the **dhcpv6-pool** command to bind a DHCPv6 address pool with a hot backup context. If the IP addresses of STAs are on the hot backup AC, you need to bind the DHCPv6 address pool to realize synchronization of DHCPv6 entries between the active and standby ACs. After the DHCPv6 address pool is bound with the context, allocated IP addresses in this DHCPv6 address pool can be synchronized from the active AC to the standby AC.
- Run the **vrrp interface** command to bind a VRRP group with a context if 802.1x or Web authentication must support the hot backup function. After a VRRP group is bound with a context, the virtual IP addresses in this VRRP group will determine the active/standby relationship based on the hot standby status.

Command	**ap-group** *ap-group*
Parameter Description	*ap-group*: indicates the name of an AP group.
Defaults	No AP group is bound.
Command	Hot backup context mode

Mode	
Usage Guide	N/A

Command	**dhcp-pool** *pool-name*
Parameter Description	*pool-name*: indicates the name of a DHCP address pool.
Defaults	No DHCP address pool is bound.
Command Mode	Hot backup context mode
Usage Guide	You can run the **show wlan hot-backup dhcp-pool config** command to check the binding configurations of a DHCP address pool.

Command	**dhcpv6-pool** *pool-name*
Parameter Description	*pool-name*: indicates the name of a DHCPv6 address pool.
Defaults	No DHCPv6 address pool is bound.
Command Mode	Hot backup context mode
Usage Guide	You can run the **show wlan hot-backup dhcpv6-pool config** command to check the binding configurations of a DHCPv6 address pool.

Command	**vrrp interface** *interface-name* **group** *vrrp-group*
Parameter Description	*interface-name*: indicates the interface corresponding to the VRRP group. *vrrp-group***:** indicates the ID of the VRRP group.
Defaults	No VRRP group is bound.
Command Mode	Hot backup context mode
Usage Guide	You can run the **show wlan hot-backup vrrp config** command to check the binding configurations of a VRRP group.

Enabling Hot Backup

- (Mandatory) The configuration is performed on the AC.
- Unless otherwise specified, the hot backup function must be enabled on both ACs; otherwise, the hot backup function cannot take effect.
- You must ensure the consistency in configurations of the two ACs with the hot backup relationship. In particular, the configuration sequence of interface-mapping configured in AP group configuration mode must be the same on both ACs.

Command	**wlan hot-backup enable**

Parameter Description	-
Defaults	The hot backup function is disabled by default.
Command Mode	Hot backup configuration mode
Usage Guide	N/A

Verification

- On the two ACs, check whether the hot backup connection is set up normally, and whether the hot backup status is normal.

Configuration Example

1+1 A/S Networking

Scenario **Figure 1-7**	Configuration Steps	● Configure the peer IP addresses, including the IP address of AC-1 192.168.1.100 and the IP address of AC-2 192.168.1.200. ● Configure a hot backup context. In the 1+1 A/S networking mode, configure only one context on the two ACs, respectively. Note that the context IDs configured on both ACs must be the same. ● Configure the priority of AC-1 for the hot backup context. ● Configure the associated AP group. Configure the associated AP group "apg-a" in context 10 on both ACs. ● Configure the VRRP group. In the 1+1 A/S networking mode, both ACs have only one context, and the two contexts are in pairs. Therefore, you only need to configure one VRRP group, for example, VRRP

	group 1. Configure VRRP group 1 on the Vlan2 interface of two ACs, respectively. ● Enable the hot backup function.
AC-1	AC-1# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC-1(config)# wlan hot-backup 192.168.1.200 AC-1(config-hotbackup)# context 10 AC-1(config-hotbackup-ctx)# priority level 7 AC-1(config-hotbackup-ctx)# ap-group apg-a AC-1(config-hotbackup-ctx)# vrrp interface vlan 2 group 1 AC-1(config-hotbackup-ctx)# exit AC-1(config-hotbackup)# wlan hot-backup enable
AC-2	AC-2# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC-2(config)# wlan hot-backup 192.168.1.100 AC-2(config-hotbackup)# context 10 AC-2(config-hotbackup-ctx)# ap-group apg-a AC-2(config-hotbackup-ctx)# vrrp interface vlan 2 group 1 AC-2(config-hotbackup-ctx)# exit AC-2(config-hotbackup)# wlan hot-backup enable
Verification	After the hot backup relationship is set up between AC-1 and AC-2, check the hot backup configurations.
AC-1	AC-1# show wlan hot-backup wlan hot-backup peer list: ip address hot-backup state description 192.168.1.200 Enable CHANNEL_UP AC-1# show wlan hot-backup 192.168.1.200 wlan hot-backup 192.168.1.200 hot-backup : Enable connect state : CHANNEL_UP hello-interval : 2000 kplv-pkt : ip ! context 10 hot-backup role : PAIR-ACTIVE

	hot-backup rdnd state : REALTIME-SYN hot-backup priority : 7
AC-2	AC-2# show wlan hot-backup wlan hot-backup peer list: ip address hot-backup state description 192.168.1.100 Enable CHANNEL_UP AC-2# show wlan hot-backup 192.168.1.100 wlan hot-backup 192.168.1.100 hot-backup : Enable connect state : CHANNEL_UP hello-interval : 1000 kplv-pkt : ip ! context 10 hot-backup role : PAIR-STANDBY hot-backup rdnd state : REALTIME-SYN hot-backup priority : 4

1+1 A/A Networking

Scenario **Figure 1-8**	Configuration	● Configure the peer IP addresses, including the IP address of AC-1 192.168.1.100 and the IP address

Steps	of AC-2 192.168.1.200. ● Configure the contexts and bind AP groups with contexts. In the 1+1 A/A networking mode, two contexts must be configured and respectively bound with two AP groups on each of the two ACs. ● Configure the VRRP groups. In the 1+1 A/A networking mode, configure two contexts on each of the two ACs. Assume that VRRP group 1 is configured on Vlan1 interfaces of AC-1 and AC-2, and VRRP group 2 is configured on Vlan2 interfaces of AC-1 and of AC-2. Bind VRRP group 1 with context 10, and VRRP group 2 with context 20. ● Configure the hot backup priorities. For context 10, AC-1 is the active AC and therefore should be configured with the highest priority. For context 20, AC-2 is the active AC and therefore should be configured with the highest priority. ● Enable the hot backup function.
AC-1	AC-1# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC-1(config)# wlan hot-backup 192.168.1.200 AC-1(config-hotbackup)# context 10 AC-1(config-hotbackup-ctx)# ap-group apg-a AC-1(config-hotbackup-ctx)# vrrp interface vlan 1 group 1 AC-1(config-hotbackup-ctx)# priority level 7 AC-1(config-hotbackup-ctx)# exit AC-1(config-hotbackup)# context 20 AC-1(config-hotbackup-ctx)# ap-group apg-b AC-1(config-hotbackup-ctx)# vrrp interface vlan 2 group 2 AC-1(config-hotbackup-ctx)# exit AC-1(config-hotbackup)# wlan hot-backup enable
AC-2	AC-2# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC-2(config)# wlan hot-backup 192.168.1.100 AC-2(config-hotbackup)# context 10 AC-2(config-hotbackup-ctx)# ap-group apg-a AC-2(config-hotbackup-ctx)# vrrp interface vlan 1 group 1 AC-2(config-hotbackup-ctx)# exit AC-2(config-hotbackup)# context 20 AC-2(config-hotbackup-ctx)# ap-group apg-b AC-2(config-hotbackup-ctx)# vrrp interface vlan 2 group 2

```
AC-2(config-hotbackup-ctx)# priority level 7
AC-2(config-hotbackup-ctx)# exit
AC-2(config-hotbackup)# wlan hot-backup enable
```

Verification After the hot backup relationship is set up between AC-1 and AC-2, check the hot backup configurations.

AC-1

```
AC-1# show wlan hot-backup
wlan hot-backup peer list:
ip address           hot-backup           state                description
-------------------- -------------------- -------------------- ------------
192.168.1.200        Enable               CHANNEL_UP
AC-1# show wlan hot-backup 192.168.1.200
wlan hot-backup 192.168.1.200
  hot-backup     : Enable
  connect state  : CHANNEL_UP
  hello-interval : 2000
  kplv-pkt       : ip
  !
  context 10
    hot-backup role        : PAIR-ACTIVE
    hot-backup rdnd state  : REALTIME-SYN
    hot-backup priority    : 7
  !
  context 20
    hot-backup role        : PAIR-STANDBY
    hot-backup rdnd state  : REALTIME-SYN
    hot-backup priority    : 4
```

AC-2

```
AC-2# show wlan hot-backup
wlan hot-backup peer list:
ip address           hot-backup           state                description
-------------------- -------------------- -------------------- -----------
192.168.1.100        Enable               CHANNEL_UP
AC-2# show wlan hot-backup 192.168.1.100
wlan hot-backup 192.168.1.100
  hot-backup     : Enable
  connect state  : CHANNEL_UP
  hello-interval : 2000
  kplv-pkt       : ip
  !
  context 10
    hot-backup role        : PAIR-STANDBY
```

```
  hot-backup rdnd state  : REALTIME-SYN
  hot-backup priority    : 4
!
context 20
  hot-backup role        : PAIR-ACTIVE
  hot-backup rdnd state  : REALTIME-SYN
  hot-backup priority    : 7
```

N+1 A/S Networking

Scenario **Figure 1-9**	Configuration Steps	● Configure the peer IP addresses, including the IP address of AC-1 192.168.1.100, IP address of AC-2 192.168.1.200, and IP address of AC-3 192.168.1.300. Configure two peer IP address on AC-1, and different peer IP addresses correspond to different contexts. ● Configure the contexts and bind AP groups with the contexts. In the N+1 A/S networking mode, one context is configured on each of the *N* ACs, and bound with the corresponding AP group. On the standby AC (AC-1 in this example), *N* contexts must be configured and bound with AP groups on the corresponding active ACs. The AP groups configured on the *N* active ACs cannot conflict with each other. ● Configure the VRRP groups. In the N+1 A/S networking mode, one VRRP group must be configured on each of the *N* active ACs, and *N* VRRP groups must be configured on the standby AC. ● Configure the hot backup priorities. In the N+1 A/S networking mode, the priorities of contexts on the *N* active ACs must be set to the highest priority, and the priorities of contexts on the standby AC can be set to the default value 4.
AC-1	`AC-1# configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.`

	AC-1(config)# wlan hot-backup 192.168.1.200 AC-1(config-hotbackup)# context 10 AC-1(config-hotbackup-ctx)# ap-group apg-a AC-1(config-hotbackup-ctx)# vrrp interface vlan 1 group 1 AC-1(config-hotbackup-ctx)# exit AC-1(config-hotbackup)# wlan hot-backup enable AC-1(config-hotbackup)# exit AC-1(config)# wlan hot-backup 192.168.1.300 AC-1(config-hotbackup)# context 20 AC-1(config-hotbackup-ctx)# ap-group apg-b AC-1(config-hotbackup-ctx)# ap-group apg-c AC-1(config-hotbackup-ctx)# vrrp interface vlan 2 group 2 AC-1(config-hotbackup-ctx)# exit AC-1(config-hotbackup)# wlan hot-backup enable
AC-2	AC-2# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC-2(config)# wlan hot-backup 192.168.1.100 AC-2(config-hotbackup)# context 10 AC-2(config-hotbackup-ctx)# ap-group apg-a AC-2(config-hotbackup-ctx)# vrrp interface vlan 1 group 1 AC-2(config-hotbackup-ctx)# priority level 7 AC-2(config-hotbackup-ctx)# exit AC-2(config-hotbackup)# wlan hot-backup enable
AC-3	AC-3# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC-3(config)# wlan hot-backup 192.168.1.100 AC-3(config-hotbackup)# context 20 AC-3(config-hotbackup-ctx)# ap-group apg-b AC-3(config-hotbackup-ctx)# ap-group apg-c AC-3(config-hotbackup-ctx)# vrrp interface vlan 2 group 2 AC-3(config-hotbackup-ctx)# priority level 7

```
AC-3(config-hotbackup-ctx)# exit
AC-3(config-hotbackup)# wlan hot-backup enable
```

Verification

After the hot backup relationship is set up between AC-1 and AC-2 and between AC-1 and AC-3, check the hot backup configurations.

AC-1

```
AC-1# show wlan hot-backup
wlan hot-backup peer list:
ip address           hot-backup           state                description
-------------------- -------------------- -------------------- -----------

Common Errors

- N/A

1.4.2 Configuring Hierarchical AC

Configuration Effect

- Establish hot backup connections in hierarchical AC scenarios.

Notes

- The hierarchical AC roles (center AC and branch ACs) must be configured.
- After the hot backup function is enabled for a branch, the hierarchical AC role and work mode cannot be changed.
- In hierarchical AC scenarios, changing forwarding mode may lead to disconnection and reconnection of the hot backup channel. Hot backup channel cannot be established in central forwarding mode.
- In hierarchical AC scenarios, the quick-switch mode is not supported and the minimum value of **hello-interval** is 30s.

Configuration Steps

Configuring Hierarchical AC Roles

- Hierarchical AC roles must be configured in hierarchical AC scenarios.

Command	**wlan hot-backup [center | branch]**
Parameter Description	**center**: Indicates the center AC. **branch**: Indicates the branch AC.
Defaults	No hierarchical AC role is configured by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the cold Work Mode in Hierarchical AC Scenarios

- Configure the cold work mode on branch ACs that require lightweight backup.
- In cold mode, most data backup with the peer is forbidden and only little data transmission is reserved. When traffic of the center AC is heavy, configure the work mode as cold to reduce the load of the center AC. In cold mode, when a branch AC is faulty, STAs need to be re-associated and STAs' IP addresses need to be obtained again for authentication.

Command	**work-mode cold**
Parameter Description	N/A
Defaults	The work mode is normal by default.
Command Mode	Hot backup configuration mode
Usage Guide	N/A

Verification

- On the center AC and branch ACs, check whether the hot backup connection is normally established and the hot backup status is normal.

Configuration Example

Hierarchical AC Networking

Scenario **Figure 1-2**	Configuration Steps	● Configure hierarchical AC roles. Configure AC-1 as the center AC and AC-2 and AC-3 as branch ACs. ● Configure peer IP addresses. (The IP address of center AC-1 is 192.168.1.100, the IP address of branch AC-2 is 192.168.1.200, and the IP address of branch AC-3 is 192.168.1.300.) Two peer IP addresses need to be configured on AC-1. Different peer IP addresses correspond to different configuration space. ● Configure description of AC-2 as RD-Office and that of AC-3 as HR-Office. ● Configure the work mode on AC-3 as cold. ● Configure hot backup priorities. In N+1 A/S mode, the highest priority needs to be configured for hot backup instances on branch ACs, and the default priority 4 is configured for the hot backup instances on the center AC.
AC-1	AC-1# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC-1(config)# wlan hot-backup center AC-1(config)# wlan hot-backup 192.168.1.200 AC-1(config-hotbackup)# description RD_Office AC-1(config-hotbackup)# context 10 AC-1(config-hotbackup-ctx)# exit AC-1(config-hotbackup)# wlan hot-backup enable AC-1(config-hotbackup)# exit AC-1(config)# wlan hot-backup 192.168.1.300 AC-1(config-hotbackup)# description HR_Office AC-1(config-hotbackup)# work-mode cold AC-1(config-hotbackup)# context 20 AC-1(config-hotbackup-ctx)# exit AC-1(config-hotbackup)# wlan hot-backup enable
AC-2	AC-2# configure terminal

	Enter configuration commands, one per line. End with CNTL/Z. AC-2(config)# wlan hot-backup branch AC-2(config)# wlan hot-backup 192.168.1.100 AC-2(config-hotbackup)# context 10 AC-2(config-hotbackup-ctx)# priority level 7 AC-2(config-hotbackup-ctx)# exit AC-2(config-hotbackup)# wlan hot-backup enable
AC-3	AC-3# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC-3(config)# wlan hot-backup branch AC-3(config)# wlan hot-backup 192.168.1.100 AC-3(config-hotbackup)# context 20 AC-3(config-hotbackup-ctx)# priority level 7 AC-3(config-hotbackup-ctx)# exit AC-3(config-hotbackup)# wlan hot-backup enable
Verification	After the hot backup relationship is established between AC-1 and AC-2 or AC-1 and AC-3, display the hot backup configurations.

1.5 Monitoring

Displaying

Description	Command
Displays the global AC hot backup configurations.	**show wlan hot-backup** [*ip-address*]
Displays the context binding configurations of the DCHP address pool and the neighbor address.	**show wlan hot-backup dhcp-pool config** *ip-address*
Displays the context binding configurations of the DCHPv6 address pool and the neighbor address.	**show wlan hot-backup dhcpv6-pool config** *ip-address*

Description	Command
Displays the binding configurations between VRRP groups and contexts under the neighbor addresses.	**show wlan hot-backup vrrp config** *ip-address*

2 Configuring WDS

2.1 Overview

Wireless Distribution System (WDS) is a system enabling interconnection of multiple access points (APs) in wireless bridging or relay mode to interconnect distributed networks and spread wireless signals.

WDS has two working modes: Root Bridge and Non-root Bridge.

- In Root Bridge mode, the wired interfaces connect to wired networks, and the wireless interfaces are used as wireless bridges to connect to those in Non-root Bridge mode.
- In Non-root Bridge mode, the wired interfaces connect to wired networks, and the wireless interfaces are used as wireless bridges to connect to those in Root Bridge mode.

2.2 Applications

Application	Description
Static WDS Bridging	Two separate networks are interconnected via bridging.
Mobile WDS Bridging	A mobile network is interconnected to a static network via WDS bridging.
Automatic Bridging of AP Partners	Wireless signals are spread via bridging between the AP partner and common APs.

2.2.1 Static WDS Bridging

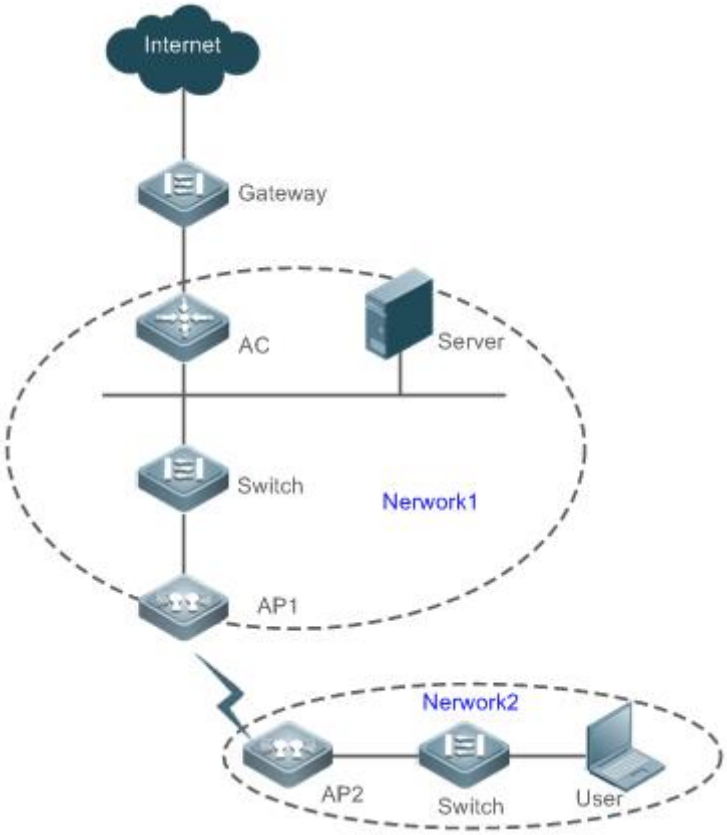
Scenario

Two separate networks are interconnected via bridging.

As shown in the following figure, Network 1 and Network 2 are interconnected via WDS bridging by AP 1 and AP 2.

- WDS bridging enables users in Network 2 to access the server in Network 1.
- WDS bridging also enables users in Network 2 to access the Internet.

Figure 2-1



Remarks	AP 1 is a root bridge. AP 2 is a non-root bridge.

Deployment

- WDS bridging is layer-2 bridging.
- WDS bridging bridges multiple VLANs transparently.

2.2.2 Mobile WDS Bridging

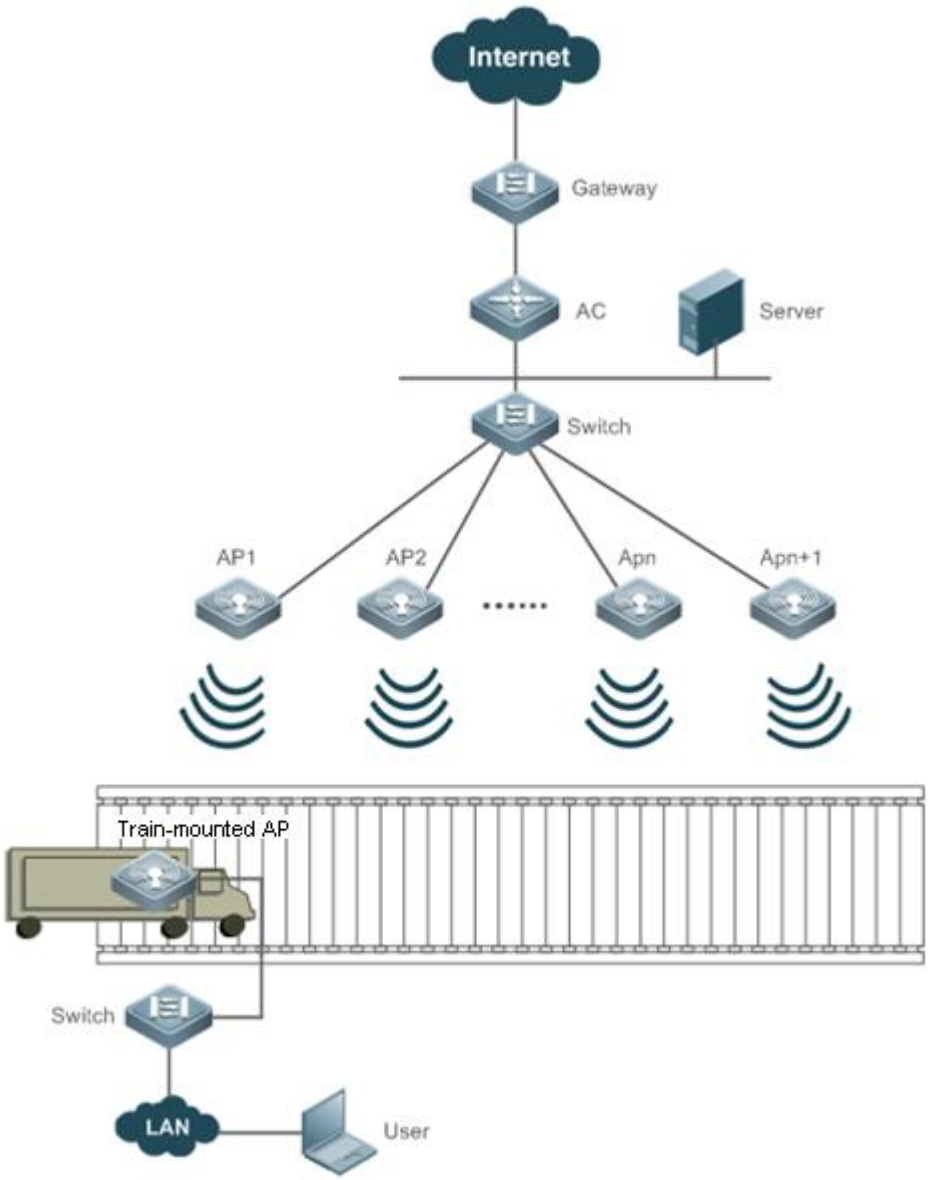
Scenario

A mobile network is interconnected to a static network via WDS bridging.

As shown in the following figure, networks are interconnected via WDS bridging between the train-mounted AP and the APs outside the train (AP 1 to AP n+1).

- When the train is advancing, users in the train can access the Server via bridging.
- When the train is advancing, users in the train can access the Internet via bridging.

Figure 2-2



Remarks	AP 1 to AP n+1 are root bridges. The train-mounted AP is a non-root bridge.

Deployment

- When the train is advancing, the non-root bridge of WDS bridging can roam and switch to a root bridge.
- WDS bridging is layer-2 bridging.
- WDS bridging bridges multiple VLANs transparently.

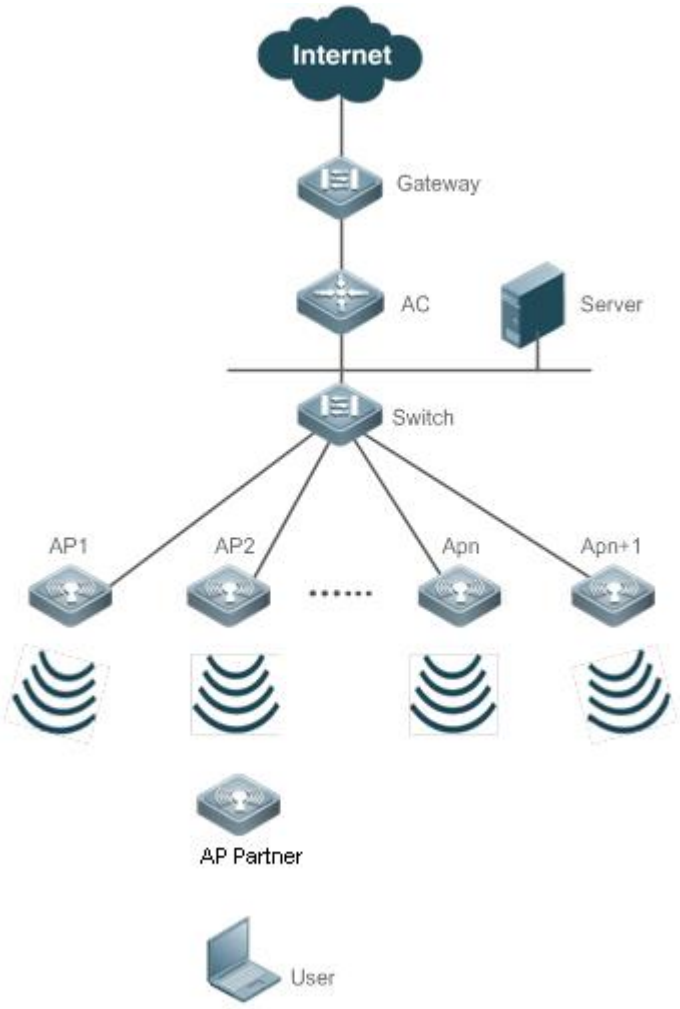
2.2.3 Automatic Bridging of AP Partners

Scenario

An AP partner is used for wireless signal spreading.

As shown in the following figure, wireless signals are spread via bridging between the AP partner and common APs.

Figure 2-3



Deployment

- The AP partner is used to achieve a large coverage of wireless signals.
- The AP partner enjoys zero-configuration.
- When automatic bridging is configured, the AP partner automatically accesses the network.

2.3 Features

Basic Concepts

Root Bridge

A root bridge is the root node in WDS bridging. It allows the access of a non-root bridge to establish WDS bridging.

Non-root Bridge

A non-root bridge is a non-root node in WDS bridging. It actively accesses the root bridge to establish WDS bridging based on user configuration.

Features

Feature	Description
Establishing WDS Bridging	Establishes WDS bridging.
Address Format of MAC Frames in WDS	Describes the address format of MAC frames exchanged between the root and non-root bridges in WDS.

2.3.1 Establishing WDS Bridging

Establish WDS bridging.

Working Principle

Each AP is a Basic Service Set (BSS). Each has a BSSID (which is usually the MAC address of an AP). An AP regularly broadcasts Beacon frames with the SSID (name of the WLAN) and BSSID, and wireless stations (STAs) listen to the Beacon frames by scanning. If the SSID of a Beacon frame is the same as the network name preset by an STA, the STA accesses the network of the AP. If multiple APs are eligible with their Beacon frames listened, the STA selects one of the APs for access. The access process is that the STA connects and associates the selected AP by recognizing the BSSID of the AP.

In WDS, the root bridge will specify a BSS used for the access of non-root bridges to establish bridging. Common STAs are not allowed to access this BSS. Only when such BSS exists will the root bridge accept the access request of a non-root bridge. During access, the root bridge will provide a mechanism to determine whether to admit a non-root bridge into its network.

For a non-root bridge, accessible root bridges are searched based on the configured BSSIDs or SSIDs. A mechanism will be provided in the searching process to determine whether a root bridge with a specified BSSID or SSID is accessible. The root bridge will be connected if accessible. In this way, WDS bridging is established.

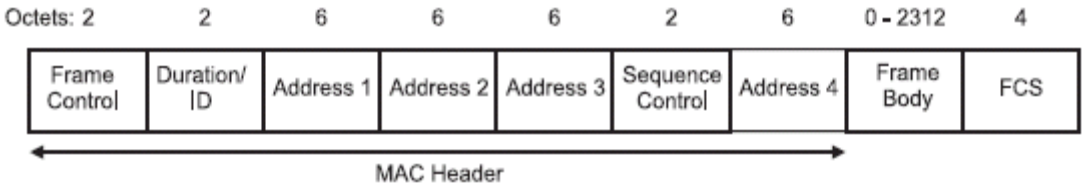
2.3.2 Address Format of MAC Frames in WDS

This section describes the address format of MAC frames exchanged between a root bridge and a non-root bridge in WDS bridging.

Working Principle

In IEEE 802.11 standards, the format of MAC frames is defined for the wireless technology which consists of a MAC header with four address fields, as shown below:

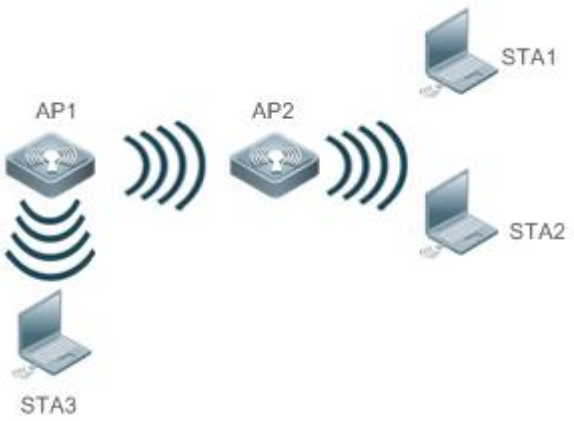
Figure 2-4



Based on the transmission modes, 802.11 MAC frames can be in three-address format or four-address format. The MAC frames in three-address format are transmitted between APs and STAs; while the MAC frames in four-address format are transmitted between APs.

As shown in the following figure, when STA 1 communicates with STA 2, STA 1 sends a MAC frame with three address fields of AP 2, STA 1 and STA 2 to AP 2 (See STA 1->AP 2 in the table). After receiving the MAC frame, AP 2 forwards it to STA 2, with three address fields changed into the MAC addresses of STA 2, AP 2 and STA 1 (see AP 2->STA 2 in the table). When STA 1 communicates with STA 3, after receiving a MAC frame from STA 1, AP 2 needs to forward it to AP 1, so the three-address format is changed to a four-address format, with the MAC addresses of AP 2, AP 1, STA 3 and STA 1 filled (see Figure 2-5). After receiving the frame, AP 1 forwards it to STA 3 and changes the four-address format back to a three-address format.

Figure 2-5



Transmission Mode	Address 1	Address 2	Address 3	Address 4
STA 1 -> AP 2	RA = AP 2	TA = STA 1	DA = STA 2	N/A
AP 2 -> STA 2	RA = STA 2	TA = AP 2	SA = STA 1	N/A
AP 2 -> AP 1	RA = AP 1	TA = AP 2	DA = STA 3	SA = STA 1

2.4 Configuration

Configuration	Description and Command
Configuring WDS Basic	(Mandatory) It is used to establish WDS bridging.

Functions	**station-role root-bridge bridge-wlan**	Configures a root bridge.
	station-role non-root-bridge	Configures a non-root bridge.
	parent	Specifies a root bridge for a non-root bridge.
	⚠ Mandatory if a non-root bridge works in fit AP mode. It is used for WDS pre-configuration.	
	wds pre-config	Pre-configures a fit non-root bridge.
	⚠ Mandatory if non-root configuration is to be modified on the AC. It is used to submit or delete the inactive WDS's commands.	
	wds config	Submits or clears inactive configuration of non-root bridges.
	⚠ (Optional) It is used to configure WDS parameters or enable the bridge coverage.	
	bridge roam-threshold	Configures the roaming thresholds of a non-root bridge.
	bridge with-client	Configures bridge coverage.
	bridge vlan	Creates a bridge VLAN.
	bridge security	Configures bridge encryption on a non-root bridge.
	wds security enable	Enables bridge encryption.
	wds-mode enable	Enables WDS bridge mode.
	autowds	Enables automatic bridging of AP partners.

2.4.1 Configuring WDS Basic Functions

Configuration Effect

- Configure WDS bridging.

Notes

- In WDS application environments, the Multiple Spanning Tree Protocol (MSTP) function must be enabled to prevent potential network loops.
- Meanwhile, the Address Resolution Protocol (ARP) agent must be disabled.
- The WDS configuration commands can be used for bridging establishment only. They must collaborate with other commands to build a test environment, such as the commands for BBS creation or wireless interface configuration.
- In WDS, the fit APs need to support Control and Provisioning of Wireless Access Points (CAPWAP) by Bridge-Group Virtual Interface (BVI) by default.

Configuration Steps

↘ **Configuring the WDS Mode**

- Mandatory.
- Configure the WDS bridge mode on ACs for fit APs.
- Run the **wds-mode enable** command to configure an AP to work in WDS bridge mode.

Command	**wds-mode {enable | disable}**
Parameter Description	**enable**: Enables the WDS bridge mode. **disable**: Disables the WDS bridge mode.
Defaults	The WDS bridge mode is disabled by default.
Command Mode	AP configuration mode on the AC
Usage Guide	Run the **show ap-config wds-mode summary** command on the AC to check whether the WDS mode is enabled for the corresponding AP. Run the **show wds-mode** command on the AP to check whether the WDS mode is enabled for the corresponding AP. AP will restart after the command is executed.

Configuring a Root Bridge

- Mandatory.
- Configure bridge coverage on ACs for fit APs.
- Run the **station-role root-bridge bridge-wlan** *wlan-id* command to configure an AP working in the mode of WDS bridging.
- Specify a WLAN to bridge BSSs. If the WLAN has not been created, WDS bridging cannot work.

Command	**station-role root-bridge bridge-wlan** *wlan-id* [**radio** *radio-id*]
Parameter Description	**bridge-wlan** *wlan-id*: Specifies a bridge WLAN. **radio** *radio-id*: Specifies a radio.
Defaults	root-ap configuration mode
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring a Non-Root Bridge

- Mandatory.
- Configure bridge coverage on ACs for fit APs.
- On a non-root bridge, you must specify a radio to work in the Non-root Bridge mode.
- Run the **station-role non-root-bridge** command to configure an AP working in the Non-root Bridge mode of WDS bridging.
- A non-root bridge starts to establish and process WDS bridging only after a destination root bridge is specified.

Command	**station-role non-root-bridge** [**radio** *radio-id*]
Parameter Description	**radio** *radio-id*: Specifies a radio.

Defaults	root-ap configuration mode
Command Mode	AP configuration mode
Usage Guide	The configurable VLAN number varies with the product model.

Specifying a Root Bridge for a Non-root Bridge

- Mandatory.
- Configure bridge coverage on ACs for fit APs.
- Two ways are available for specifying a root bridge to access: specifying its BSSID or SSID.
- Specifying the BSSID of a root bridge: This is applicable to a static root bridge.
- Specifying the SSID of a root bridge: This will enable the non-root roaming function to select the root bridge with the best signals for access.
- Run the **parent** { **mac-address** *HHHH.HHHH.HHHH* | **ssid** *ssid* } [**channel** *channel* **chan-width** *chan-width*] command to specify the BSSID or SSID of a root bridge to be accessed by a non-root bridge.

Command	**parent** { **mac-address** *HHHH.HHHH.HHHH*	**ssid** *ssid* } [**radio** *radio-id*]
Parameter Description	**mac-address** *HHHH.HHHH.HHHH*: Specifies the BSSID of a root bridge for static bridging. **ssid** *ssid*: Specifies the SSID of a root bridge optimal for roaming. **radio** *radio-id*: Specifies a radio.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	Non-root bridges start searching root bridges after this command is executed. If WDS bridging is required, this command must be configured on the non-root bridges.

Configuring the Roaming Thresholds of a Non-Root Bridge

- Optional.
- Configure bridge coverage on ACs for fit APs and on APs for fat APs.
- This command is configured to adjust roaming parameters.
- Generally, the configuration of these thresholds is not required unless in special environments (where the roaming parameters need to be adjusted).
- This command requires professionals to propose suitable configuration after measuring and analyzing the application environments. It is not recommended to configure this command without the assistance of professionals; otherwise, the WDS's roaming effect and even the use of WDS bridging will be affected.

Command	**bridge roam-threshold** *num1 num2 num3 num4* [**radio** *radio-id*]
Parameter Description	*num1*: Roaming start threshold, 40 by default. *num2*: Scanning start threshold, 15 by default. *num3*: Roaming switch threshold, 5 by default.

	num4: Roaming switch time threshold, 5 by default. **radio** *radio-id*: Specifies a radio.
Defaults	Enabled.
Command Mode	AP configuration mode
Usage Guide	Generally, the configuration of these thresholds is not required unless in special environments (where the roaming parameters need to be adjusted).

Configuring Bridge Encryption on a Non-Root Bridge

- Optional.
- Configure bridge coverage on ACs for fit APs.
- This command is configured to adjust encryption parameters.
- This configuration is required only when bridging is required for accessing an encrypted network.
- The encryption parameters must be configured the same as those of the encrypted network to be accessed; otherwise, the bridging may fail.

Command	**bridge security** [**radio** *num*] { **wpa** | **rsn** } **ciphers** { **aes** } **akm psk key** { **ascii** | **hex** } *key*
Parameter Description	**radio** *num*: Indicates a configured RF port. **wpa | rsn**: Configures WPA or RSN authentication. **aes**: Configures AES encryption. **psk**: Configures PSK access authentication. **ascii**: Specifies ASCII as PSK format. **hex**: Specifies Hex as PSK format. *key*: When the ASCII form is selected, the key has a length ranging from 8 to 63 ASCII characters. When the Hex form is selected, the key has a length with 64 hexadecimal characters.
Defaults	No encryption parameter is configured.
Command Mode	Fat AP: AP configuration mode
Usage Guide	The encryption parameters must be configured the same as those of the encrypted network to be accessed; otherwise, the bridging may fail.

Creating or Creating a Bridge VLAN

- Optional.
- This is configured only on ACs in fit AP mode.
- If you need to create a VLAN independently on an AP, you must conduct this configuration on the AC.

Command	**bridge vlan** *vid*
Parameter Description	*vid*: ID of the VLAN to be created
Defaults	N/A

Command Mode	AP configuration mode
Usage Guide	Use this command to create a WDS VLAN in coordination with other VLAN creation commands.

Configuring Bridge Coverage

- Optional.
- In Root Bridge mode: Configure bridge coverage on ACs for fit APs. In Non-root Bridge mode: Configure bridge coverage on APs for fit APs by pre-configuration.
- This command is optional if the WDS does not need the bridge coverage function. This command is mandatory if the bridge coverage function is required.
- This command is not recommended so that the coverage function is disabled during bridging.

Command	**bridge with-client{ enable** | **disable** } [**radio** *radio-id*]
Parameter Description	**enable**: Enables bridge coverage. **disable**: Disables bridge coverage. **radio** *radio-id*: Specifies a radio.
Defaults	Bridge coverage is disabled by default.
Command Mode	AP configuration mode
Usage Guide	It is recommended to disable bridge coverage.

Configuring the Front and Back Channels of a Non-root Bridge

- Optional.
- This function is configured on non-root bridge scenarios like subway trains where the front and back of AP channels may be changed.
- After this commanded is configured, the channel of a non-root bridge changes based on the working status.

Command	**wds head-chan** *num1* **tail-chan** *num2* [**radio** *radio-id*]
Parameter Description	*num1*: Front channel *num2*: Back channel **radio** *radio-id*: Specifies a radio.
Defaults	Disabled.
Command Mode	Fit AP: Interface configuration mode Fat AP: AP configuration mode
Usage Guide	This is configured only on the non-root bridges. Configure this function on a non-root fat AP directly in fat AP mode and on the in fit AP mode. Only after being committed will the configuration take effect.

Enabling Bridge Encryption

- Optional.

- This is configured when the non-root and root bridges need encrypted communication in WDS.
- This command must be consistently configured on the root and non-root bridges, otherwise, the communication fails.

Command	**wds security enable**[**radio** *radio-id*]
Parameter Description	**radio** *radio-id*: Specifies a radio.
Defaults	Bridge encryption is disabled by default.
Command Mode	Fat AP: AP configuration mode
Usage Guide	On the AC, configuration is directly pushed for root bridges and pushed only after being committed for non-root bridges.

Pre-configuring a Fit Non-root Bridge

- Optional.
- When a non-root bridge needs to work in fit AP mode, the pre-configuration must be conducted on fat APs.
- First of all, conduct required non-root configuration (including configuring the working mode as NONROOT-BRIDGE and specifying information on the root bridges to be accessed).

Command	**wds pre-config**[**delete**] [**radio** *radio-id*]
Parameter Description	**delete**: Deletes pre-configuration. **radio** *radio-id*: Specifies a radio.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	In turn, to exit the bridging mode, run the **wds pre-config delete** command to delete the non-root pre-configuration.

Clearing or Submitting Inactive WDS Configuration

- Optional.
- Use this command to submit inactive commands.
- Changes in the configuration of non-root bridges on the AC cannot take effect immediately. To issue the changes, you must run the **wds config commit** command.

Command	**wds config**[**clear | commit**] **radio** *radio-id*
Parameter Description	**clear**: Clears inactive WDS configuration. **commit**: Submits inactive WDS configuration. After submitting, the bridging will be re-established. **radio** *radio-id*: Specifies a radio.
Defaults	N/A
Command Mode	AP configuration mode

Enabling Automatic Bridging of AP Partners

- Optional.
- This command can be configured in all/standalone AP configuration mode (single AP), or AP group configuration mode, with the priority order: standalone AP configuration mode > AP group configuration mode > all AP configuration mode.
- After this command is configured and a root AP receives a request from the AP partner (non-root), WDS is created automatically.

Command	**autowds**
Parameter Description	N/A
Defaults	Automatic bridging is disabled by default.
Command Mode	All/standalone AP configuration mode or AP group configuration mode
Usage Guide	This function is required not for normal non-root bridges but for AP partners.

Verification

run the **show** command to display WDS configuration.

Configuration Example

WDS Roaming Scenario in Fit AP Mode

In this scenario, APs are required to establish a CAPWAP link through BVI by default.

Scenario **Figure 2-6**	Configuration Steps	● Configure the WLAN, VLAN, and channels for AP 1 to AP n+1. (This scenario needs a unified channel.) ● The above configuration is the same as that in common AP application scenarios. ● Configure the WDS's root bridges and specify a WLAN used for bridging. ● Configure the WDS's non-root bridge. Pre-configuration is used for the non-root bridge. (Assuming that the bridge WLAN is **ruijie-root** and the channel is 149 with the bandwidth of 40 MB)
ROOT **(AP1 - APn+1)**	Ruijie#configure terminal Ruijie(config)#ap-config ap1 Ruijie(config-ap)# station-role root-bridge bridge-wlan 1 radio 2

NONROOT (In-vehicle AP)	Ruijie#configure terminal Ruijie(config)#interface dot 2/0 Ruijie(config-if-Dot11radio 2/0)# station-role non-root-bridge Ruijie(config-if-Dot11radio 2/0)# parent ssid ruijie-root Ruijie(config-if-Dot11radio 1/0)# wds pre-config create Ruijie(config-if-Dot11radio 1/0)# exit Ruijie(config)#ap-mode fit
Verification	Run the following command to display WDS bridging information.
In-vehicle AP	Ruijie#show dot11 wds-bridge-info 1/0 WDS-MODE: NONROOT-BRIDGE MAC:00d0.f822.3304 WBI 1/0 ROOT 32d0.f822.3303
On the AC	Display WDS bridging information on the interface. Ruijie#show ap-config wds-bridge-info summary Ap Name Mac Address Radio Station Role ---------- ---------- ----- ---------- Ap-001 00d0.f822.3301 2 ROOT-BRIDGE Ap-002 00d0.f822.3304 2 NON-ROOT-BRIDGE Ruijie# show ap-config wds-bridge-info Ap-001 radio 2 WDS-MODE: ROOT-BRIDGE BRIDGE-WLAN: Status OK WlanID 1, SSID ruijie_root, BSSID 32d0.f822.3303 WBI 1/0 NONROOT 00d0.f822.3304

Common Errors

N/A

2.5 Monitoring

Displaying

Description	Command
Displays the WDS bridge configuration on an AP.	**show wds-mode**
Displays the WDS bridge configuration on an AC.	**show ap-config wds-mode summary**
Displays WDS links on an AC.	**show ap-config wds-bridge-info** { **summary** |*ap-name* **radio** *radio-id* }
Displays WDS configuration on an AC.	**show ap-config wds-config** [*ap-name*]

3 Configuring RIPT

3.1 Overview

The Remote Intelligent Perceptive Technology (RIPT) is also known as the smart AP technology. As a wireless network edge device (as compared with an AC), the smart AP can perceive its connection with the AC and take over external provision of wireless networks seamlessly once connection fails. The wireless RIPT solution can be deployed in enterprise branch networks for the availability and sustainability of inter-WAN networks between the AC and APs in case of faults. It can also be deployed in a Wireless Local Area Network (WLAN) network to reduce reliance on ACs and improve its availability.

Protocols and Standards

N/A

3.2 Applications

Application	Description
Deploying RIPT in a WLAN network	Both the AC and APs are deployed in a Local Area Network (LAN) network.
Deploying RIPT in enterprise branch networks	The AC is deployed in the enterprise headquarters, while APs are deployed in various branches and connected to the AC through a WAN network.

3.2.1 Deploying RIPT in a WLAN Network

Scenario

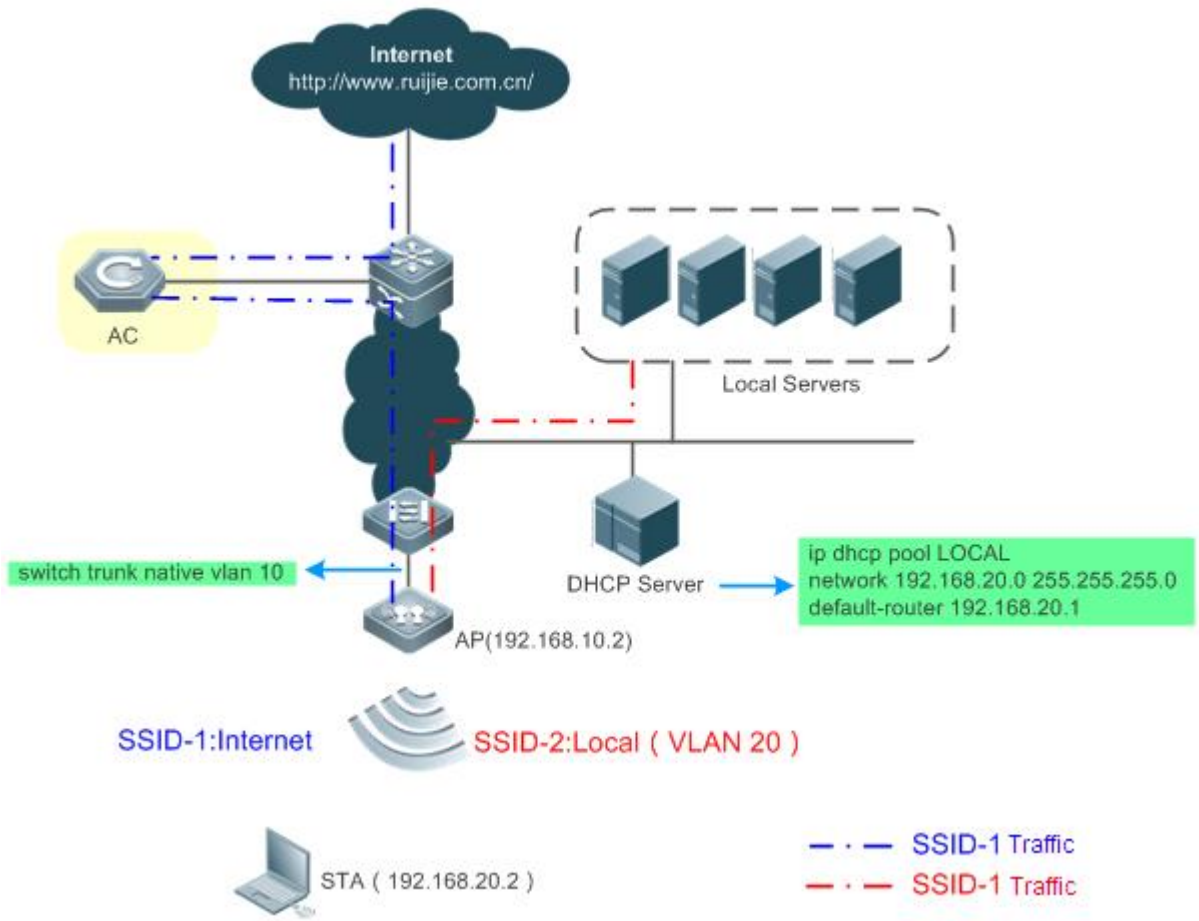
The following are two types of RIPT WLANs to meet service requirements:

- WLAN for operators' Internet services: applies centralized forwarding and 802.1x/Web authentication mode. There is potential demand for accounting.
- WLAN for LAN resource services: applies local forwarding and WAP\WAP2-PSK authentication mode.

When the AC is unreachable (such as restart or outage), the wireless network can still access local resources.

For example, as shown in Figure 3-1, the AC is unreachable while the other devices such as switches and APs are normal. The WLAN service is not affected and continues to be available.

Figure 3-1



Remarks	The DHCP server for allocating an IP address to the STA cannot be configured on the AC. The AC cannot forward data traffic for SSID-2 that uses local forwarding.

Corresponding Protocols

- Create a WLAN, and configure the forwarding mode and the security policy.
- Enable RIPT on the APs.

3.2.2 Deploying RIPT in Enterprise Branch Networks

Scenario

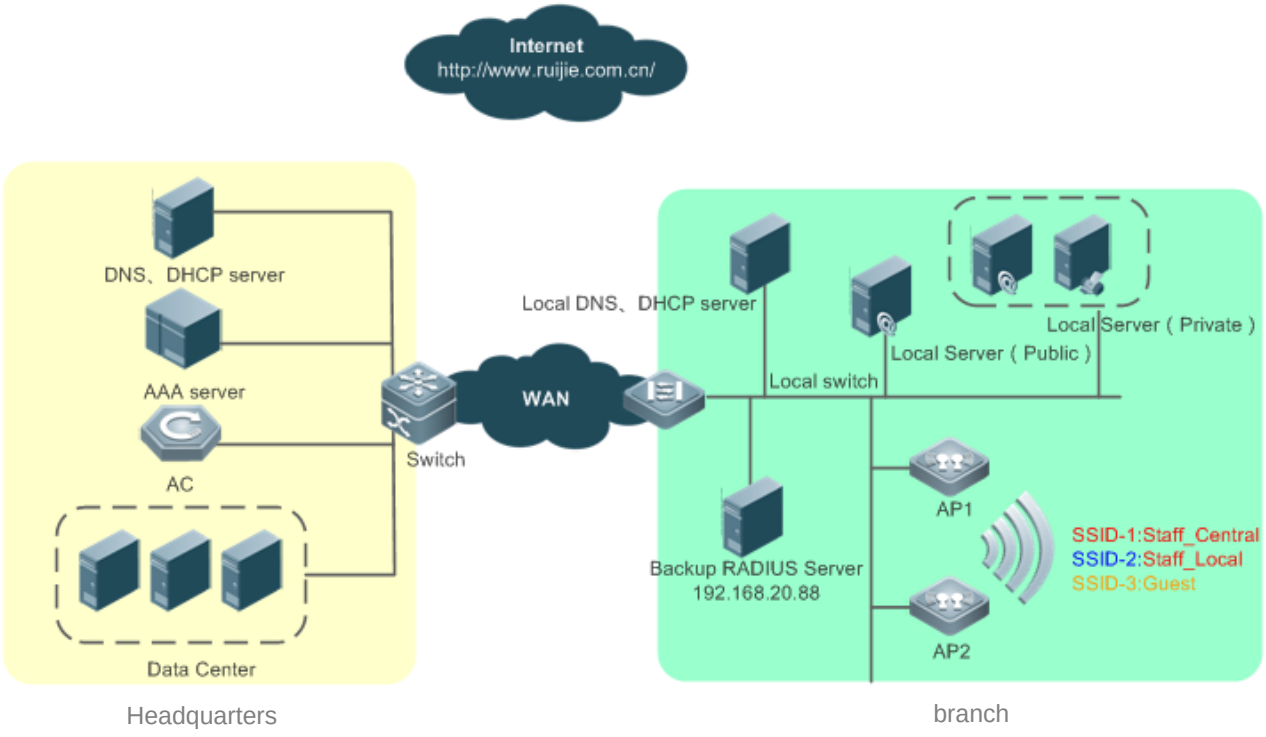
The following are requirements for the enterprise branch networks:

- An AC is deployed in the headquarters data center, while some APs and a DHCP server are deployed in the branches to serve STAs.
- A RADIUS server is deployed in the headquarters to perform access authentication for STAs in both the headquarters and all branches. If a backup RADIUS server is not deployed in the branch, access authentication for STAs in the branch fails when the APs in the branch are disconnected from the headquarters AC (for example, when the WAN fails).

- Traffic for accessing the headquarters data center will pass the WAN between the branch and the headquarters, whereas traffic for accessing local resources and Internet resources of the branch is forwarded in the branch instead of passing the WAN.

As shown in Figure 3-2, when the route from a branch AP to the headquarters AC is unreachable, the branch AP can still provide network for local resource access or the like.

Figure 3-2



Remarks	The AC is deployed in the headquarters and connected with APs through the WAN. A DHCP server for IP address allocation is deployed in the branch. If there is no backup RADIUS server in the branch, STA access authentication will stop when the WAN link fails. If 802.1X authentication is adopted, another WLAN can be deployed and the function of SSID enabling after connection interruption can be enabled, so that the WLAN can provide network services for new STAs when the AP connection is interrupted. Free Web authentication after connection interruption can be enabled to ensure that Web-authenticated STAs can access the network after the AP connection is interrupted.

Deployment

- Deploy a WLAN for employees in the branch to access the headquarters data center. Enable the centralized forwarding mode. The STA access authentication runs in the headquarters.
- Deploy a WLAN for employees in the branch to access Internet resources and local resources. Enable the local forwarding mode and the 802.1x local authentication. When an AP works in connected mode, the headquarters RADIUS server performs the authentication. When the AP works in standalone mode, another WLAN can be deployed

and the function of SSID enabling after connection interruption can be enabled, so that the WLAN can provide network services for new STAs; or the 802.1X authentication is prohibited for the new STAs for the security purpose.

- Deploy a WLAN for guest access on Internet resources and public resources of the branch. Enable the local forwarding mode and the Web local authentication. When an AP works in connected mode, the headquarters RADIUS server performs the authentication. When the AP works in standalone mode, free Web authentication can be enabled to ensure that new STAs can access the network.
- Create an AP group, and configure WLAN to VLAN mapping.
- Configure the APs, add them to the AP group, and enable the RIPT function.

3.3 Features

Basic Concepts

Connected Mode and Standalone Mode

When a CAPWAP tunnel has been established between an AP and an AC, the working environment of the AP is referred to as connected mode.

When the CAPWAP tunnel between the AP and the AC is broken, the working environment of the AP is referred to as standalone mode.

RIPT AP

An RIPT-enabled AP is called an RIPT AP. It is also known as a smart AP.

AC Configuration Change Monitoring

After re-establishing a CAPWAP tunnel in standalone mode with the AC, an RIPT AP should check the AC configuration change, so as to determine whether to maintain the online status of online STAs accordingly. Therefore, AC configuration should be monitored, so as to determine whether it has changed when the RIPT AP is offline.

A configuration change is considered as having taken place when one of the following operations is performed:

- The AC enters the configuration mode with CLI commands, or a CLI command has been executed in the configuration mode.
- A SET operation has been performed on the AC through SNMP.

If either of the above two cases occurs on the AC when the AP is offline, the configuration of the AC is considered as having changes. Then online STAs will be brought offline when the AP is reconnected to the AC.

In case all configuration of the AC has been stored in its Flash memory, when the AC is restarted (or powered on following powered off) and the configuration file in the Flash memory does not change, the configuration of the AC is considered as having no change.

Overview

Feature	Description

Enabling the RIPT Function	The AP automatically detects its connection to the AC. When the connection to the AC is broken, the AP continues to provide services by smoothly switching to the standalone mode.
Enabling SSID After Connection Interruption	After the AP connection is interrupted, the WLAN provides SSID signals for STAs to access the network. In normal cases, this function is used together with 802.1X authentication.
Enabling Free Web Authentication After Connection Interruption	After the AP connection is interrupted, STAs can access WLANs adopting Web or MAB authentication without performing Web or MAB authentication.

3.3.1 Enabling the RIPT Function

An AP becomes an RIPT AP only after the RIPT function is enabled. When the AP detects that its connection to the AC is broken, the AP automatically switches to the standalone mode. After a connection to the AC is re-established, the AP switches back to the connected mode.

Working Principle

When the WLAN is set to the local forwarding mode, an RIPT AP has the same the working mechanism with a common fit AP in connected mode. The AC performs STA association and authentication. After a new STA gets online, the AC backs up its information in real time to the associated RIPT AP. Then the RIPT AP creates STA information and a backup entry. When detecting that its CAPWAP connection to the AC is broken, the RIPT AP automatically switches to the standalone mode. After that, online STAs will maintain their online status while new STAs can get online. If the WLAN works in centralized forwarding mode, online STAs will be brought offline and SSID broadcast is automatically disabled.

In standalone mode, the RIPT AP will first detect whether the AC configuration changes after re-establishing a CAPWAP tunnel with the AC. If the configuration of the AC does not change, the RIPT AP synchronies information about all online STAs to the AC, so that the AC re-establishes STA information. After that, STA association and authentication is switched back to the AC while the RIPT AP enters the connected mode. If the configuration of the AC has changed, the RIPT AP brings offline all online STAs, receives the new configuration, and then enters the connected mode.

3.3.2 Enabling SSID After Connection Interruption

When the AP connects to the AC, STAs cannot discover SSID or access the network. When the connection between the AP and AC is interrupted, SSID is enabled for STAs to access the network. After the connection between the AP and AC recovers, the SSID becomes unavailable.

This function is used as a supplementary solution for RIPT APs adopting 802.1X authentication. After the RIPT AP connection is interrupted, network access requests from STAs using 802.1X authentication cannot be processed. To enable STAs to access the network, configure another WLAN and enable this function.

Working Principle

If the function of SSID enabling after connection interruption is enabled STAs can access the network after the AP is disconnected. After the AP connection is recovered, if the function of SSID enabling after connection interruption is enabled for the WLAN, the WLAN stops working, STAs are not allowed to access the network and online STAs become offline.

3.3.3 Enabling Free Web Authentication After Connection Interruption

When the AP connects to the AC, STAs can access the network only after Web or MAB authentication. When the connection between the AP and AC is interrupted, STAs can access the network without Web or MAB authentication. After the connection between the AP and AC is recovered, STAs can access the network after Web or MAB authentication.

Working Principle

An RIPT AP determines whether free Web authentication is enabled for the WLAN after the AP connection is interrupted. If this function is enabled for the WLAN, STAs can directly access the network. After the AP connection is recovered, STAs can access the network only after authentication.

3.4 Configuration

Configuration	Description and Command	
Configuring the RIPT Function	⚠ Mandatory configuration. Enable the RIPT function.	
	ript enable	Enables the RIPT function.
	⚠ Optional configuration. Enable SSID after connection interruption.	
	enable-ssid at-capwap-down	Enables SSID after connection interruption.
	⚠ Optional configuration. Enable free Web authentication after connection interruption.	
	free-webauth at-capwap-down	Enables free Web authentication after connection interruption.

3.4.1 Configuring the RIPT Function

Networking Requirements

- An RIPT AP can independently work when its connection to the AC is broken.
- The moment that the RIPT function is enabled or disabled, the AP actively breaks its CAPWAP connection to the AC and then re-establishes a new connection. This also happens when the AP gets online for the first time.
- After SSID is enabled after connection interruption, the WLAN works only after the AP connection is interrupted.
- After free Web authentication is enabled for a WLAN, STAs can access the network without Web or MAB authentication after the AP connection is interrupted.

Notes

- Save the configuration before restarting the AC. If the configuration is not yet saved before the AC is restarted, the restarted AC will use the configuration stored in its Flash memory. In this case, the configuration used on the RIPT AP is different from that being used on the AC after the restart and the situation is handled the same as when the AC configuration has changed. Therefore, make sure to save the configuration before restarting the AC in the RIPT scenario.

- In 802.1X authentication scenarios, STAs are not allowed to access WLANs adopting 802.1X authentication after the AP connection is interrupted.
- Configure the keep-alive time of APs. For an RIPT-enabled AP, you need to configure its keep-alive time according to the status of the previous network communications between the AP and the AC. For details, see the configuration command **echo-interval** to be executed in AP configuration mode. The purpose of doing so is to avoid instability of the CAPWAP tunnel between the AP and the AC, which may occur as a result of poor network communications between the AP and the AC.
- Certain requirements must be met during the deployment of the DHCP server. If an RIPT AP or STA acquires its IP address through DHCP and the RIPT AP works in standalone mode, the DHCP server must be reachable for the RIPT AP and STA.

Configuration Steps

Creating a WLAN and Setting It to the Local Forwarding Mode

- Mandatory configuration. If the WLAN works in centralized forwarding mode, STAs will be brought offline after the RIPT AP switches to the standalone mode.
- Create the WLAN in global configuration mode on the AC.
- By default, the WLAN works in centralized forwarding mode.
- Run the **tunnel local** command in WLAN configuration mode to set the WLAN to the local forwarding mode.

Enabling the RIPT Function

- Mandatory configuration.
- Run the **ript enable** command to enable RIPT in AP/AP group configuration mode.
- Enabling the RIPT function on an AP does not affect existing services when the AP is normally connected to the AC.

Command	**ript enable**
Parameter Description	N/A
Defaults	The RIPT function is disabled.
Command Mode	AP configuration mode/ AP group configuration mode
Configuration Usage	N/A

Enabling or Disabling the AC Configuration Change Monitoring Function

- Optional configuration.

Command	**ript-monitor** { **enable** | **disable** }
Parameter Description	**enable**: Enables the AC configuration change monitoring function. **disable**: Disables the AC configuration change monitoring function.
Defaults	The AC configuration change monitoring function is enabled.
Command Mode	Privileged EXEC mode or global configuration mode
Configuration Usage	N/A

Enabling SSID After Connection Interruption

- Optional
- Perform this operation in WLAN configuration mode.
- If the RIPT function is not enabled for the AP, this function does not take effect. After the AP connection is interrupted, SSID signals are not provided.
- Run the **enable-ssid at-capwap-down** command in WLAN configuration mode to enable SSID after connection interruption.

Command	enable-ssid at-capwap-down
Parameter Description	N/A
Defaults	By default, the function of SSID enabling after connection interruption is disabled.
Command Mode	WLAN configuration mode
Usage Guide	This function needs to be enabled only if 802.1X authentication is used.

Enabling Free Web Authentication After Connection Interruption

- Optional
- Perform this operation in WLAN configuration mode.
- Free Web authentication after connection interruption is performed only after this function is enabled on WLANs adopting web or MAB authentication.

Command	free-webauth at-capwap-down
Parameter Description	N/A
Defaults	By default, free web authentication after connection interruption is disabled.
Command Mode	WLAN configuration mode
Usage Guide	This function needs to be enabled only on WLANs adopting Web or MAB authentication.

Verification

- Run the **show ap-config summary ript-enable** command to check whether the RIPT function is enabled on the AP.
- Run the **show running-config** command to check whether the functions of SSID enabling after connection interruption and free Web authentication after connection interruption are enabled.
- When the AC is normally connected, STAs can normally get online. When the AC is restarted or disconnected, online STAs can maintain normal communications and new STAs can normally access the network.
- For WLANs with the function of SSID enabling after connection interruption enabled, SSID signals are provided only after the AP connection is interrupted.
- For WLANs enabling web authentication and free Web authentication after connection interruption, STAs can access the network without web authentication only after the AP connection is interrupted.

Configuration Steps

Configuring the RIPT Function

Scenario **Figure 3-3**	Configuration Steps	● Create a WLAN, and set it to the local forwarding mode and. ● Configure an AP group, specify WLAN mapping for the AP group. ● Configure the APs, add them to the AP group, and enable the RIPT function on the APs. ● For 802.1X authentication, enable the function of SSID enabling after connection interruption. ● For Web authentication, enable free Web authentication after connection interruption.

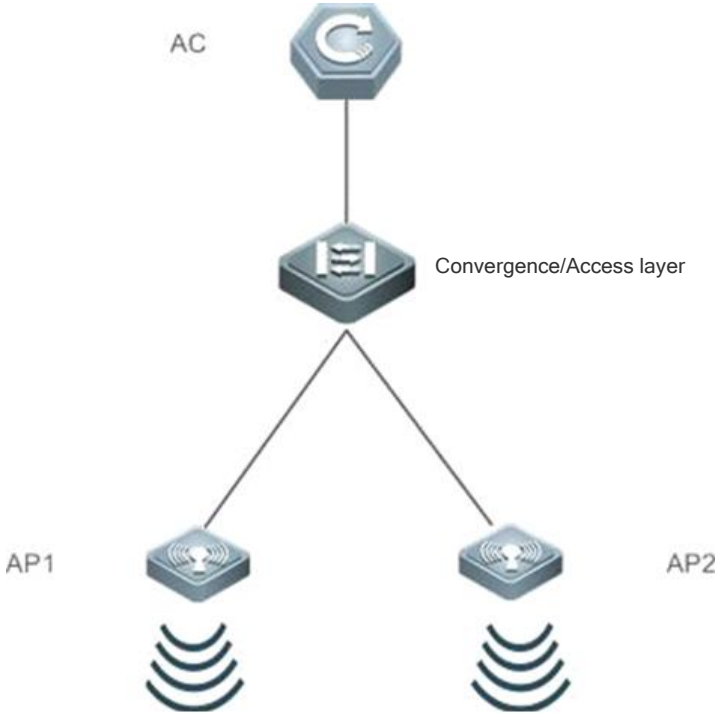
4 Configuring Virtual AC

4.1 Overview

In an AC+fit AP distributed network, there are thousands of and even tens of thousands of APs. How to guarantee reliability of wireless access is essential in a large-scale network.

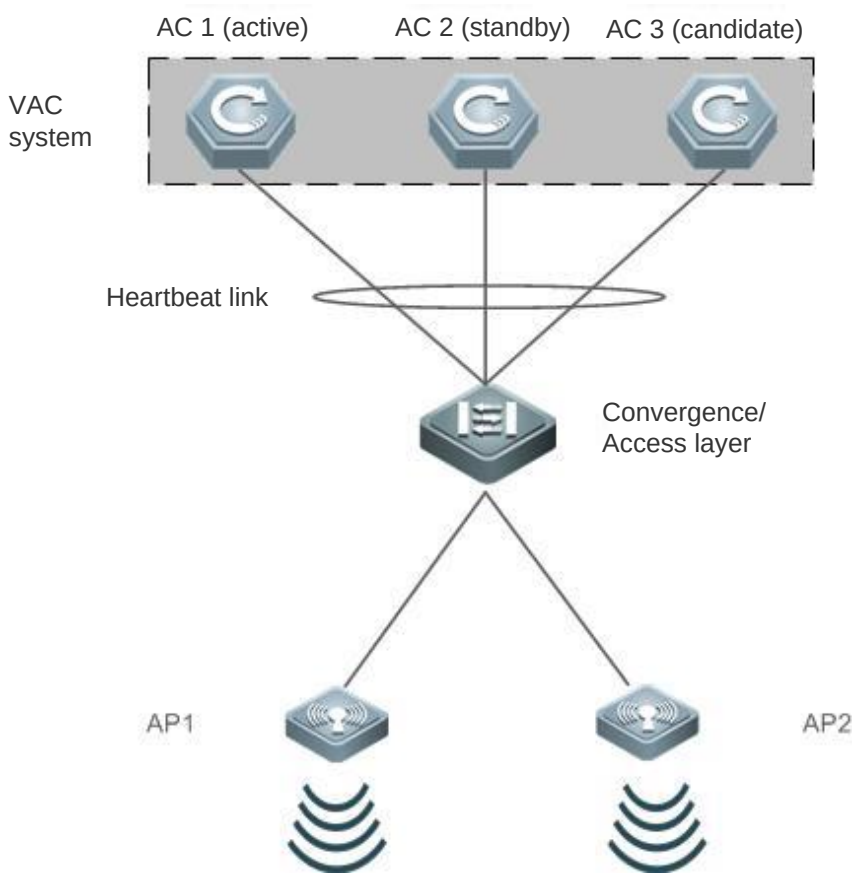
In existing AC+fit AP networking mode, an AP discovers the AC via the Control and Provisioning of Wireless Access Points (CAPWAP) protocol. The AP can receive services from the AC only after being successfully registered and associated with the AC. As a result, the process in which an AP detects whether the AC is faulty via CAPWAP keepalive packets is very time-consuming. If an AC malfunctions, all APs need to re-register with another AC. The incurred network interruption duration imposes great impact on enterprises. How to shorten the switch time to reduce impact on the network is an issue to be urgently resolved.

Figure 4-1 Conventional Network Structure



Virtual AC (VAC) is a network system virtualization technology capable of combining multiple ACs into one virtual device. As shown in Figure 4-2, multiple ACs of the same model can form a VAC system. In comparison with the conventional networking mode, this networking simplifies the network topology, reduces network management and maintenance costs, shortens the application recovery time and service interruption time, and improves network resource utilization.

Figure 4-2 VAC Networking Mode



4.2 Applications

Application	Description
Managing Multiple Devices in Unified Manner	Multiple physical devices compose one logical device for unified management.
Improving the Reliability	Multiple devices are available for fast switching, thereby improving the reliability.

4.2.1 Managing Multiple Devices in Unified Manner

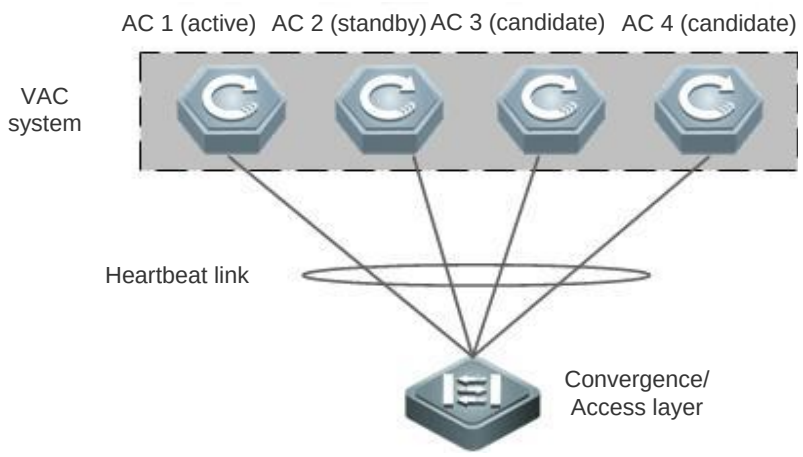
Scenario

When multiple physical devices compose a VAC system, the VAC system can be considered as one logical device. All configurations are managed on the global active device.

As shown in Figure 4-3, four devices (numbered 1, 2, 3, and 4 from left to right in sequence) compose a VAC system. Device 1 is the global active device, Device 2 is the global standby device, and Device 3 and Device 4 are global candidate devices.

- Configurations only need to be performed on the active device for device management.

Figure 4-3



Remarks	The devices are numbered 1, 2, 3, and 4 from left to right in the figure above. For the heartbeat link, see descriptions in section 1.3.1. Device 1 serves as the global active device. Device 2 serves as the global standby device. Device 3 and Device 4 serve as the global candidate devices.

Deployment

- The active device is responsible for controlling the entire VAC system, running the management plane protocols, running the control plane protocols of the active device, and participating in data forwarding.
- The standby device is responsible for running the control plane protocols of the standby device, participating in data forwarding, and taking over the work of the active device when the active device malfunctions.
- Global candidate devices are responsible for running the control plane protocols of the candidate devices and participating in data forwarding. When the global standby device malfunctions, a global candidate device can take over the work of the global standby device and serves as the global standby device. A global candidate device cannot take over the work of the global active device. Therefore, when the global active device and the global standby device malfunction at the same time, the VAC system restarts.
- Control plane protocols are mutually backed up among the devices.

4.2.2 Improving the Reliability

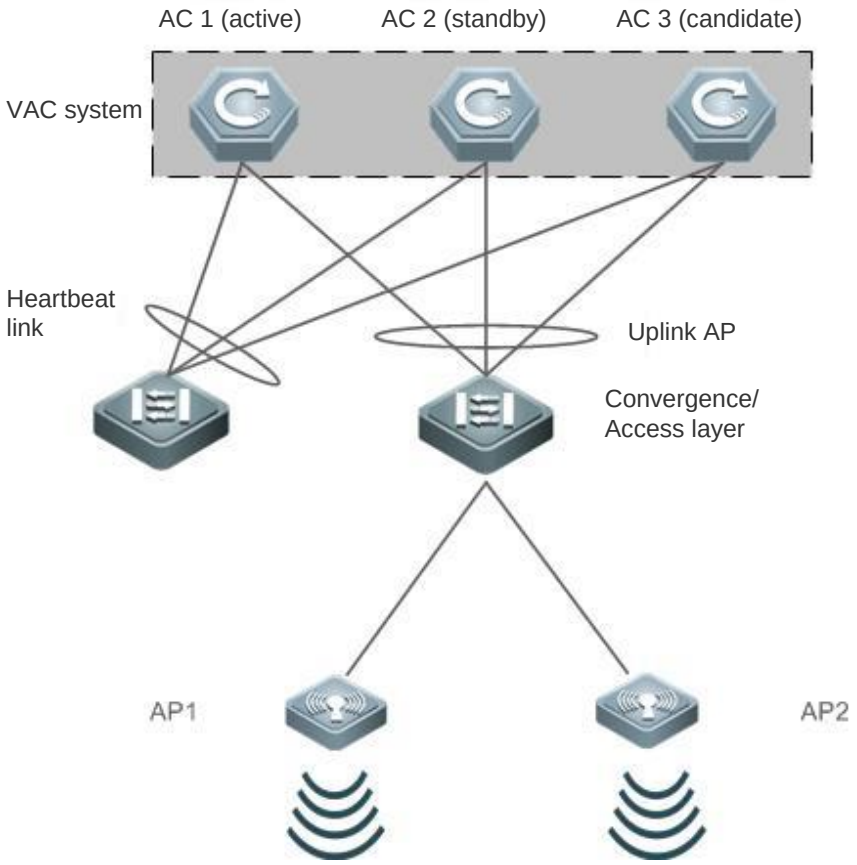
Scenario

As shown in Figure 4-4, when the AC malfunctions, all APs registered with the AC drop out of the network. The APs need to rediscover another AC and complete the registration so as to reconnect to the network. All devices in a VAC system are considered as one logical device. A device in the VAC system mutually serves as a backup of other devices. When one device malfunctions, services and data can be rapidly migrated to another device.

- Multiple ACs form a VAC system and the ACs provide mutual redundancy. System management is conducted on the active device.

- A heartbeat link is configured between ACs to provide a data channel and exchange data. ACs are connected to the access/convergence layer through the uplink AP.
- When one device in a VAC system malfunctions, other devices work properly.

Figure 4-4



Deployment

- The active device is responsible for managing the entire VAC system, running the management plane protocols, running the control plane protocols of the active device, and participating in data forwarding.
- The global standby device is responsible for participating in data forwarding, running the control plane protocols but not the management plane protocols, and taking over the work of the global active device when the global active device malfunctions.
- The heartbeat link occupies an independent port on the AC, and services are not configured on the port.

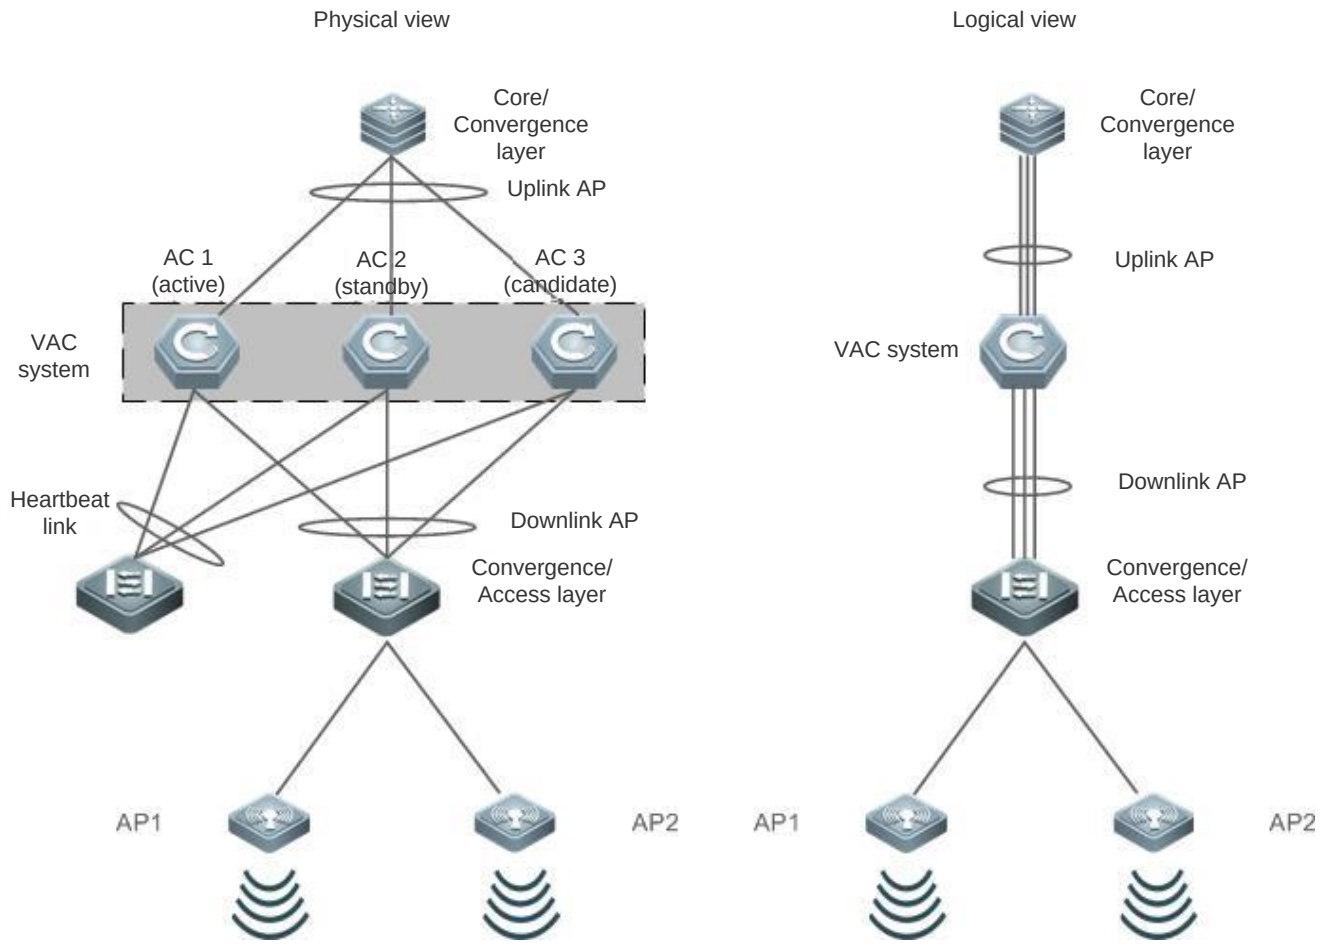
4.3 Features

Basic Concepts

VAC System

A VAC system is a single logical entity composed of multiple independent ACs in the conventional network structure that are connected through internal heartbeat links. A VAC system can be considered as an independent AC for management.

Figure 4-5 VAC System



Domain ID

A VAC system has a unique domain ID. Only devices with the same domain ID can form a VAC system.

Device ID

Each member device in a VAC system has a unique device ID. This device ID facilitates management on member devices. When adding a device to a VAC system, you need to configure a device ID for the device and ensure that the device ID is unique in the VAC system. If device IDs of member devices conflict in a VAC system, one member device is retained according to the priority.

Device Role

When a VAC system is built, one device is elected as the active device, and another device is elected as the standby device according to the election protocol mechanism, the standby device and the rest devices serve as candidate devices. The

active device is responsible for controlling the entire VAC system, running the management plane protocols of the VAC system, running the control plane protocols of the active device, and participating in data forwarding. The standby device and candidate devices do not run management plane protocols, but run their respective control plane protocols and participate in data forwarding. When the active device fails, the standby device serves as the active device to manage the VAC system.

The active device of a VAC system is elected as follows:

1. The rules for active device election are as follows (if the active device cannot be elected according to the previous rule, the system goes on with the next rule for judgment): (a) The current running device is elected as the active device preferentially (No device is the active device during startup). (b) A member device with the highest priority is elected as the active device. (c) A member device with a smaller device ID is elected as the active device. (d) A member device with a smaller MAC address is elected as the active device.
2. The VAC system supports the joining of a device in hot mode. The system does not perform active/standby switching even if a device that joins the VAC system in hot mode has a higher priority than the active device in the VAC system.
3. The startup sequence of member devices may affect election of the active device. Some member devices may not join the VAC system in time due to slow startup (currently, the VAC system directly conducts convergence if it does not discover a neighbor within 5 minutes). In this case, the member device will join the VAC system in hot mode. Even if its priority is higher than the current running active device in the VAC system, the system does not perform active/standby switching.

Overview

Feature	Description
Heartbeat Link	Describes relevant features of the heartbeat link of the VAC system.
Topology	Describes the topology structure of the VAC system.
Dual-Active Detection	Prevents the coexistence of dual active devices in the same VAC system domain.
External Connections of Devices in the VAC System	Describes the connections between external devices and devices in the VAC system.
System Management	Manages devices in the VAC system.

4.3.1 Heartbeat Link

Working Principle

Heartbeat Link

The active and standby devices in a VAC system are network entities and they need to transmit management information to each other. Heartbeat links are special links for transmitting management information (including role election information and configuration backup information) and data streams between devices in the VAC system. Users can configure one or more heartbeat links between two member devices of a VAC system. Two heartbeat links are recommended for scenarios with high reliability requirements.

After the VAC system is established, if one heartbeat link fails, the VAC system automatically adjusts the configuration so that the backup traffic is not transmitted via the failed link.

If all heartbeat links are disconnected, the topology of the VAC system is split, and the standby device automatically becomes the active device. The configurations of the two devices are the same, which will trigger dual-active detection. One of the two active devices will enter the recovery state and the service port on the device is disabled, so as avoid impact on services in the user network.

If the active device malfunctions, the standby device can detect the fault of the active device via the heartbeat link, automatically becomes the active device, and takes over services.

Heartbeat links can be directly connected or connected through a Layer-2 switch.

Heartbeat Link Traffic

Data streams transmitted by heartbeat links between devices are classified into the following:

- Flooding data streams in a VLAN
- Data streams to be forwarded between devices, which need to be transmitted via heartbeat links.

In addition, heartbeat links also transmit internal management packets of the VAC system, for example, hot backup control plane protocol information, and packets that carry the configuration to be delivered from the active device to other member devices.

4.3.2 Topology

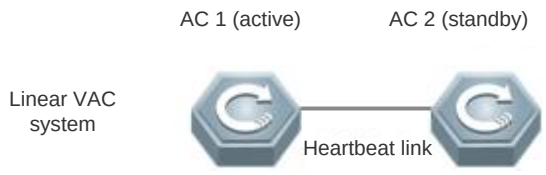
The VAC system supports the linear topology structure and star topology structure. Devices are connected through a heartbeat link, which can be considered as a line and this topology is called linear topology. Multiple ACs are connected through a Layer-2 switch and the topology in this structure is called star topology.

Working Principle

Topology Structure

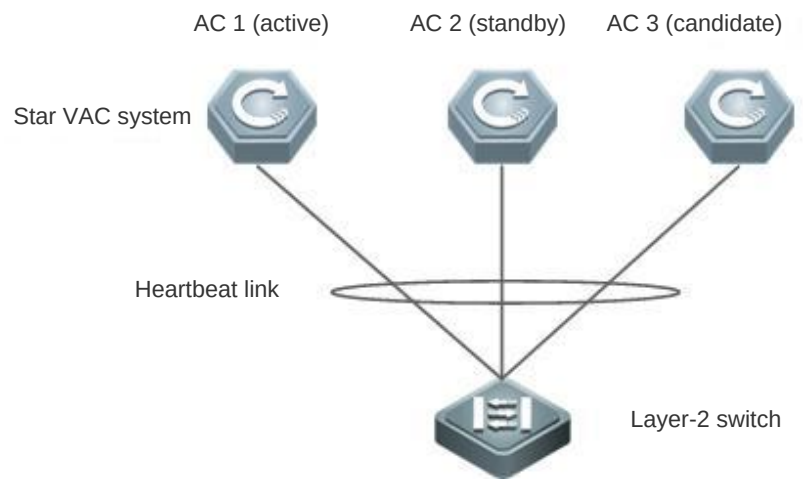
In the linear topology, ACs are directly connected via a heartbeat link. Currently, a linear VAC system can be composed of only two devices. A VAC system consisting of three or more devices must use the star topology.

Figure 4-6 Linear Topology



As shown in Figure 4-7, ACs can be connected through a Layer-2 switch to form a star topology. This topology reduces the number of the ports occupied by heartbeat links.

Figure 4-7 Star Topology



Topology Election

Before a VAC system is established, member devices discover their neighbors via the topology discovery protocol, to determine the devices that compose the VAC system, so as to determine the scope of the management domain. Then, one active device is elected to manage the VAC system and one standby device is elected as the backup of the active device. At this point, the topology of the VAC system is converged. The topology discovery protocol information is transmitted via heartbeat links. The startup time of different devices is different. Therefore, the first convergence time of the topology is different.

The rules for active device election are as follows (active device election starts from the first rule; if the active device is not elected according to the current rule, the system goes on with the next rule for judgment):

- Topology convergence status. The device whose topology is converged is elected as the active device preferentially.
- Priority. The device with a higher priority is elected as the active device.
- If the active device cannot be determined according to the preceding rules, the device with a smaller device ID will prevail.
- If the active device cannot be determined according to the preceding rules, the device with a smaller MAC address will prevail.

The rules for standby device election are as follows (standby device election starts from the first rule; if the standby device is not elected according to the current rule, the system goes on with the next rule for judgment):

- Compare with the ID of the switch connected to the active device. The device that does not reside on the same switch as the active device is preferentially elected as the standby device. If multiple devices are not on the same switch as the active device, go on with the next rule for judgment.
- Priority. The device with a higher priority is elected as the standby device.
- If the standby device cannot be determined according to the preceding rules, the device with a smaller device ID will prevail.

- If the standby device cannot be determined according to the preceding rules, the device with a smaller MAC address will prevail.

Topology Combination

When two or more ACs with the same domain ID are connected via heartbeat links, the topologies will be combined. One device will restart and join the VAC system in hot mode during topology combination.

The topology combination rules are as follows (the topology combination starts from the first rule. If the optimal topology is not selected according to the first rule, the system goes on with the next rule for judgment):

- The user configuration is prior to other configuration. The device configured with the highest priority will prevail.
- If the active device cannot be determined according to the preceding rule, the device with a smaller device ID will prevail.
- If the active device cannot be determined according to the preceding rule, the device with a smaller MAC address will prevail.

Heartbeat Link Passing Through a Layer-2 Network

In a star topology environment, heartbeat links are not directly connected, and a Layer-2 switch is used to forward management packets carried over the heartbeat links. In a VAC system, management packets of devices cannot be forwarded across VLANs. Therefore, on the Layer-2 switch, heartbeat link ports of multiple ACs must be configured to be in the same VLAN. It is recommended to configure a separate VLAN for AC heartbeat link ports on the switch, so as to prevent other ports in the same VLAN from interfering with management packet forwarding.

4.3.3 Dual-Active Detection

Working Principle

When the heartbeat link is disconnected, the standby device becomes the active device. If the original active device is still running, there are two active devices and IP address conflict and other problems will be incurred in the LAN because they have the same configuration. In this case, the VAC system must detect whether dual active devices coexist, and take recovery measures.

Rules of Dual-Active Detection

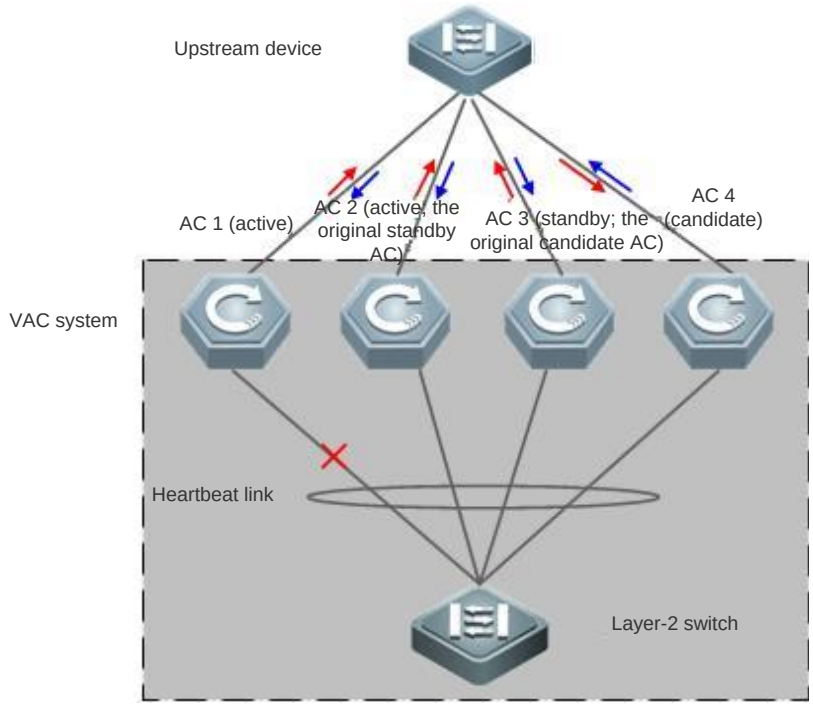
1. The device with a higher priority will prevail.
2. If the active device cannot be determined according to the preceding rule, the device with a smaller device ID will prevail.
3. If the active device cannot be determined according to the preceding rules, the device with a smaller MAC address will be retained.
4. If the active device cannot be determined according to the preceding rules, the device with longer startup time will be retained.

If dual-active detection is not configured, the network will be interrupted after the topology is split.

Dual-Active Detection Mode

The VAC system supports the dual-active detection mechanism by using an aggregate port. Figure 4-8 shows the connection topology. Both the VAC system and upstream device need to support the dual-active detection function of the aggregate port. When a heartbeat link is disconnected and dual active devices coexist, both active devices send inspection packets to each member port of the aggregate port. The inspection packets are transferred by the upstream device to the other active device. As shown in Figure 4-8, the aggregate port contains four member ports, each of which is connected to one device in the VAC system. When the topology is split, the four member ports send and receive inspection packets to detect the coexistence of dual active devices. Then, according to certain rules (same as topology combination rules), the VAC system where one active device resides will be shut down to enter the recovery state, so as to prevent network abnormalities.

Figure 4-8 Dual-Active Detection



4.3.4 Traffic Forwarding

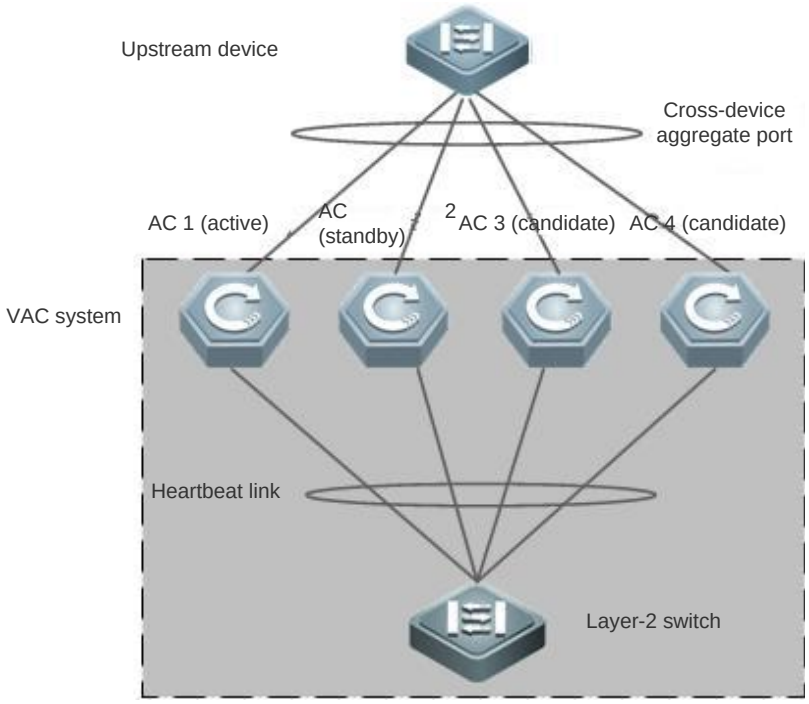
Working Principle

Cross-device Aggregate Port Group

An AP binds multiple physical connections to form a logical connection. The VAC system supports the AP across member devices.

As shown in Figure 4-9, four ACs compose the VAC system and the upstream device is connected to the VAC system as an AP. For the upstream device, the AP connections are equivalent to a common aggregate port group.

Figure 4-9 Cross-device Aggregate Port



Troubleshooting

It is recommended that a peripheral device be physically connected to each device in the VAC system when a cross-device AP is configured for the VAC system. This can ensure the bandwidth of heartbeat links on one hand (the cross-device AP preferentially selects the AP member port as the traffic outlet, to prevent transmission of unnecessary traffic via heartbeat links), and improve the network reliability on the other hand (if a device malfunctions, member ports on the normal devices can work properly).

The possible cross-device AP failures and incurred impact are described as follows:

- A single link fails.

If a single link of the cross-device AP fails but other links function properly, the cross-device AP re-distributes traffic among the remaining normal links.

- On the global active device, links of all cross-device AP member ports fail.

If links of all cross-device AP member ports on the global active device fail, only member ports on other member devices continue to work properly. If the forwarding egress port of data streams coming from the AP to the VAC system is located on the global active device, the VAC system forwards the data streams to the egress port of the global active device via heartbeat links.

Control plane protocols run on each device. Therefore, protocol packets transmitted to the VAC system are forwarded to each device for protocol computing via the heartbeat links.

- All links to other member devices fail.

If all links between the cross-device AP and Member Device A fail, only member ports on other member devices continue to work properly. If the forwarding egress port of data streams coming from the AP to the VAC system is located on Member Device A, the VAC system forwards the data streams to the egress port of Member Device A via heartbeat links.

- All links fail.

If all links of the cross-device AP fail, the cross-device AP changes the port state to Link-Down, just as a common AP does.

- The global active device malfunctions.

If the active device malfunctions, hot backup switching is triggered and the original standby device becomes the active device. Meanwhile, member ports on other member devices continue to work properly. When the peer device in the VAC system that is connected to the cross-device AP detects a link failure, it adjusts the load balancing algorithm to distribute data streams to normal links.

- A member device malfunctions.

If a member device malfunctions, the AP member ink connected to the member device is disconnected but other member links still work properly. When the peer device in the VAC system that is connected to the cross-device AP detects a link failure, it adjusts the traffic balancing algorithm to distribute data streams to normal links.

Traffic Balancing

There may multiple traffic egresses in a VAC system. The AP and Equal-cost Multi-path Routing (ECMP) have their own traffic balancing algorithms, for example, traffic is balanced based on the source and destination MAC addresses. For details, see the AP and ECMP configuration manuals. In this configuration manual, packets received by the local device can be configured to be preferentially forwarded by the local device. In this way, packets can be forwarded to other devices not through heartbeat links.

4.3.5 System Management

Working Principle

Console Access

The console of the active device in the VAC system is also used to manage multiple devices in the system. On the console of the standby device, CLI commands cannot be executed, but the protocol status of the standby device can be queried and protocol entries can be cleared. On the active device, users can configure services for member devices in a unified manner. Users can also log in to the console of the active device through the serial port of the standby device. In addition, users can redirect to the console of a device by running run the **session** command.

Interface Naming

In VAC system work mode, the same port ID may appear on multiple devices. Therefore, the device ID is introduced to interface naming.

For example, interface gigabitEthernet 1/0/1 indicates the GE Port 1 in Slot 0 of the device with the ID of 1; interface gigabitEthernet 2/0/2 indicates the GE Port 2 in Slot 0 of the device with the ID of 2.

System Upgrade

Usually, the main program versions of member devices in the VAC system need to be consistent. However, there are numerous member devices and the upgrade is time-consuming, laborsome, and error-prone if the devices are upgraded in standalone mode. Currently, a perfect system upgrade solution is available. You can complete the system upgrade by using the two methods below:

- When the VAC system is established, the system automatically checks the main program version of all member devices. If inconsistency is identified, the system synchronizes the main program of the active device to all member devices.
- After the VAC system is established, the system automatically synchronizes the file downloaded over TFTP to all member devices.

System Logs

System logs can be printed on all member ports of the VAC system. System logs generated by the active device are directly printed on the console of the active device, and the format of printed system logs is identical to that of system logs printed in standalone mode. System logs generated by other member devices are also printed on the console of the active device, but the format of printed system logs is different from that of system logs printed in standalone mode because the device ID is printed.

For example, the system log generated in standalone mode is "%DEVICE-6-INSTALL: Install chassis WS5708 on device 1." The system log generated by the member device with the device ID of 2 should be "%DEVICE-6-INSTALL: (2*)Install chassis WS5708 on device 1.

4.3.6 Standby Device Preemption

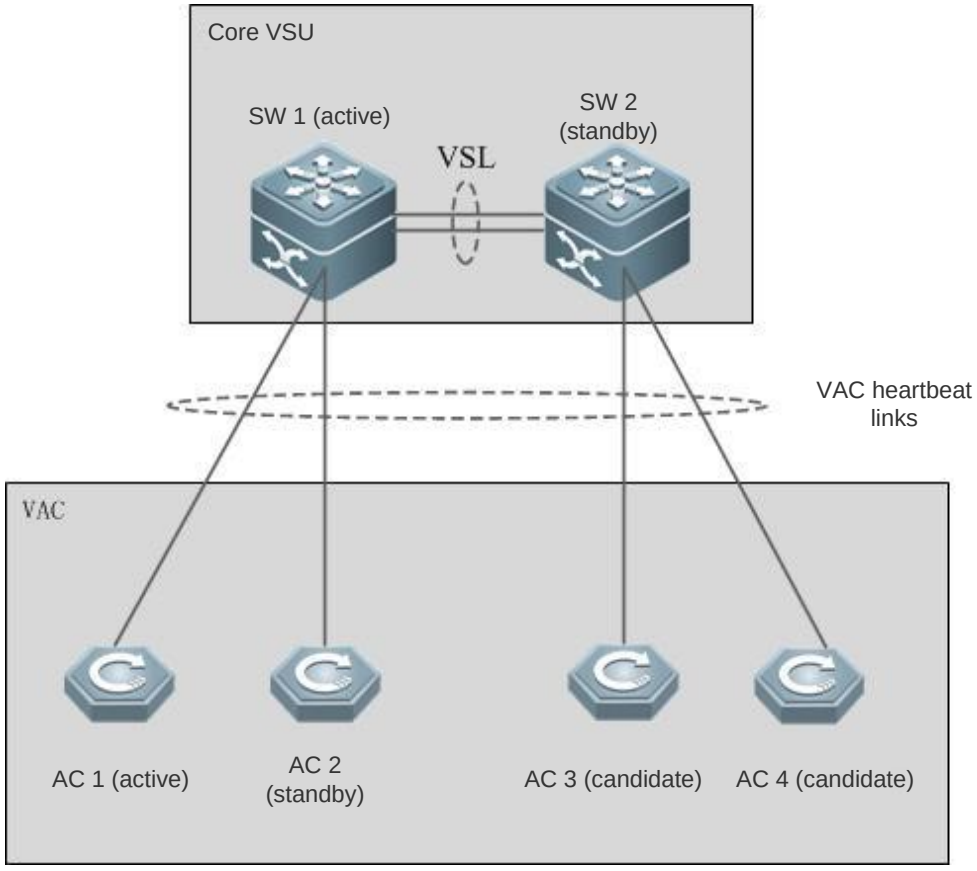
Working Principle

Standby Device Preemption

The VAC system supports the standby device preemption function. If a new device that joins the VAC system has a higher priority than the existing standby device in the VAC system, the new device will preempt the standby device role.

As shown in Figure 4-10, SW 1 and SW 2 compose a VSU, ACs 1-4 are connected to the two switches and form a VAC system. The active and standby devices of the VAC system connect to SW 1 and the candidate ACs are connected to SW 2.

Figure 4-10 VSU+VAC



When the core VSU malfunctions, SW 1 resets, which will result in splitting of the VAC system. AC 1 and AC 2 cannot communicate with external devices, resulting in the AP drop-out. AC 3 and AC 4 have no standby devices and will reset for recovery upon splitting. Therefore, when one switch in the VSU malfunctions, all ACs will become unavailable, which is contradictory to the original intention of the VAC system, and backup cannot be performed correctly.

The standby device preemption function can properly solve this problem. ACs with high priority are connected to different switches. In this way, the active and standby devices in the VAC system are connected to different switches. When the VSU malfunctions, one switch resets, ACs connected to the other switch can take over services properly, preventing unavailability of all ACs.

4.4 Configuration

Configuration	Description and Command	
Configuring Basic VAC System Parameters in Standalone Mode	⚠ (Mandatory) It is used to configure VAC system parameters in standalone mode.	
	virtual-ac domain	Configures the domain ID.
	device	Configures the device ID in the VAC system.

		device priority	Configures the device priority.
		device connect_switch	Configures the ID of the switch connected to the AC.
		vac-port	Enters the heartbeat port configuration mode.
		port-member interface	Adds a common port to the heartbeat link port pool.
		device convert mode vitual	Switches the device from the standalone mode to the VAC mode.
Configuring VAC System Parameters in VAC Mode	Configuring VAC System Attributes	⚠ (Optional) It is used to configure device attributes in VAC mode.	
		device domain	Changes the domain ID of the device.
		device renumber	Changes the device ID.
		device description	Configures the device alias.
	Configuring Heartbeat Links	⚠ (Optional) It is used to configure heartbeat links.	
		vac-port	Enters the heartbeat port configuration mode.
		port-member interface	Adds a common port to the heartbeat link port pool.
	Configuring Dual-Active Detection	⚠ (Mandatory) It is used to configure the dual-active detection function.	
		dual-active detection	Configures the dual-active detection function.
		dual-active bfd interface	Configures a BFD detection port.
		dual-active interface	Configures the aggregate port as the dual-active detection port.
		dual-active exclude interface	Configures an excluded port.
	Configuring Standby Device Preemption	**slave preemtive enable**	Configures standby device preemption.
	Switching the Device from VAC Mode to Standalone Mode	⚠ (Optional) It is used to switch the device from the VAC mode to the standalone mode.	
		device convert mode standalone	Switches the device from the VAC mode to the standalone mode.
Monitoring	Displaying Current Running Status	⚠ Optional.	
		show virtual-ac	Displays information about the currently running VAC system, topology structure, or current VAC system parameters.

		show virtual-ac dual-active	Displays the current dual-active detection configuration.
		show virtual-ac link	Displays the heartbeat link running status in VAC mode.
		session	Redirects to the console of the active device or any device.

4.4.1 Configuring Basic VAC System Parameters in Standalone Mode

Configuration Effect

Configure VAC-relevant basic parameters, so as to build a VAC system.

Configuration Steps

Configuring VAC System Attributes

- Configure the same domain ID for multiple devices that need to compose a VAC system and ensure that the domain ID is unique in the LAN. In addition, configure a device ID for each device in the VAC system.
- Run the **vitrual-ac domain** *domain_id* command to configure the domain ID. This command is mandatory.
- Run the **device** device_*id* command to configure a device ID for each device in the VAC system. This command is mandatory. When devices share the same priority, the device with a smaller device ID is preferentially elected as the primary device.
- Run the **device** *device_id* **priority** *priority_num* command to configure the device priority. This command is optional. The value ranges from 1 to 255. A larger value indicates a higher priority.

Command	**virtual-ac domain** *number*
Parameter Description	*number*: Indicates the virtual domain ID of a VAC system.
Defaults	The default domain ID is 100.
Command Mode	config-vac-domain configuration mode
Usage Guide	Only devices with the same domain ID can compose a VAC system. The domain ID must be unique in the LAN.

Command	**device** *device_id*
Parameter Description	*device_id*: Indicates the ID of a device in the VAC system. The value varies with the product model.
Defaults	The default device ID is 1.
Command Mode	config-vac-domain configuration mode

Usage Guide	The device with a smaller device ID is elected as the active device if two devices are both active devices or if the two devices share the same priority and are just started with their roles not determined. This command can be used to change the ID of an AC only in standalone mode. The changed device ID takes effect only after device restart.

Command	**device** *device_id* **connect_switch** *switch_id*
Parameter Description	*device_id*: Indicates the ID of the device with the priority to be configured. *switch_id*: Indicates the device ID. The value ranges from 1 to 255.
Defaults	The default switch ID is 1.
Command Mode	config-vac-domain configuration mode
Usage Guide	Set the ID of the connected switch. If the specified switch ID is different from that of the active device, the device will be preferentially elected as the standby device. This command is available in both the standalone mode and VAC mode. The changed priority takes effect only after the device restart. In VAC mode, *device_id* indicates the ID of the currently running device. If the device ID does not exist, the priority configuration does not take effect.

Command	**device** *device_id* **priority** *priority_num*
Parameter Description	*device_id*: Indicates the ID of the device with the priority to be configured. priority_num: Indicates the device priority. The value ranges from 1 to 255.
Defaults	The default priority is 100.
Configuration Mode	config-vac-domain configuration mode
Usage Guide	A larger value indicates a higher priority. The device with a higher priority is elected as the active device. This command is available in both the standalone mode and VAC mode. The changed priority takes effect only after device restart. In VAC mode, *device_id* indicates the ID of the currently running device. If the device ID does not exist, the configuration does not take effect.

The priority configuration command is used to change the priority only and will not change the device ID. Therefore, a correct device ID must be entered during configuration. For example, the configured device ID is 1. If you enter the **device 2 priority 100** command, the priority does not take effect.

Configuring Heartbeat Links

- Some ports need to be configured as heartbeat detection ports so as to establish a VAC system.
- Run the **vac-port** command to enter the heartbeat port configuration mode. This command is mandatory.
- Run the **port-member interface** *interface-name* [**copper** | **fiber**] command to add heartbeat ports. This command is mandatory.

- When the device enters the heartbeat port configuration mode, you can configure or delete heartbeat ports.

Command	**vac-port**
Parameter Description	N/A
Defaults	N/A
Command Mode	Configuration mode
Usage Guide	This command is available in both the standalone mode and VAC mode.

Command	**port-member interface** *interface-name* [**copper | fiber**]
Parameter Description	*interface-name*: Indicates a 2D port name, for example, Tengigabitethernet 1/1 and Tengigabitethernet 1/3. **copper**: Indicates the electrical port attribute. **fiber**: Indicates the SFP port attribute.
Defaults	*N/A*
Command Mode	config-vac -port configuration mode
Usage Guide	Add member ports for the heartbeat links. *interface-name* indicates the 2D port name in standalone mode. It can be a 10GE port or a GE port (the GE port can be an SFP combo port. If the medium type is not specified, the GE port is a GE electrical port by default). The optical/electrical attribute must be specified for SFP combo ports. This command is available in both VAC mode and standalone mode.

⚠ In standalone mode, the heartbeat port configuration does not take effect immediately. It can take effect only after the device switches to VAC mode and is restarted.

Verification

Run the **show virtual-ac config** [*device_id*] command to display the VAC system configuration on the current device in standalone mode.

Command	**show virtual-ac config [** *device_id* **]**
Parameter Description	*device_id*: Indicates the device ID. If this parameter is specified, only the VAC system configuration of a specific device is displayed.
Command Mode	Privileged EXEC mode
Usage Guide	Display the VAC system configuration in standalone mode or VAC mode.

⚠ The VAC-relevant configuration is applicable to a single physical device, and the configuration is stored in the special configuration file **config_vac.dat**. Therefore, the **show running config** command cannot display VAC system

configuration. Only the **show virtual-ac** config command can be executed to display the configuration of the current VAC system.

In standalone mode, the running information of the VAC system is blank. When the **show virtual-ac** command is executed, a prompt is displayed, indicating that the current work mode is standalone mode and there is no VAC system running information.

Configuration Example

Configuration Example

Scenario **Figure 4-11**	 AC 1 and AC 2 form a VAC system. The domain ID is 100. The device ID and priority of AC 1 are 1 and 200 respectively. Ports 0/1 and 0/2 are heartbeat ports. The device ID and priority of AC 2 are 2 and 100 respectively. Ports 0/1 and 0/2 are heartbeat ports.
Configuration Steps	1) Complete the following configuration on AC 1: ● Configure the VAC system attributes and heartbeat ports. ● Switch the device from the standalone mode to VAC mode. 2) Complete the following configuration on AC 2: ● Configure the VAC system attributes and heartbeat ports. ● Switch the device from the standalone mode to VAC mode.
Device-1	Ruijie# configure terminal Ruijie(config)# virtual-ac domain 100 Ruijie(config-vac-domain)#device 1 Ruijie(config-vac-domain)#device 1 priority 200 Ruijie(config-vac-domain))#exit Ruijie(config)# vac-port Ruijie(config-vac-port)#port-member interface GigabitEthernet 0/1 Ruijie(config-vac-port)#port-member interface GigabitEthernet 0/2 Ruijie(config)#exit
Device-2	Ruijie# configure terminal Ruijie(config)# virtual-ac domain 100 Ruijie(config-vac-domain)# device 2 Ruijie(config-vac-domain)# device 2 priority 200 Ruijie(config-vac-domain))#exit Ruijie(config)# vac-port

	Ruijie(config-vac-port)#port-member interface GigabitEthernet 0/1 Ruijie(config-vac-port)#port-member interface GigabitEthernet 0/2 Ruijie(config-vac-port)#exit
Verification	● Run the **show virtual-ac config** command to display the VAC system attributes of AC 1 and AC 2.
Device-1	Ruijie#show virtual-ac config device_id: 1 (mac: 1414.4b5b.54f8) ! virtual-ac domain 100 ! device 1 device 1 priority 200 ! device convert mode virtual ! port-member interface GigabitEthernet 0/1 ! port-member interface GigabitEthernet 0/2 !
Device-2	Ruijie#show virtual-ac config device_id: 2 (mac: 00d0.f822.33c0) ! virtual-ac domain 100 ! device 2 device 2 priority 100 ! device convert mode virtual ! port-member interface GigabitEthernet 0/1 ! port-member interface GigabitEthernet 0/2 !

4.4.2 Configuring VAC System Parameters in VAC Mode

4.4.2.1 Configuring VAC System Attributes

Configuration Effect

After devices compose a VAC system or when the VAC system is running, if some parameters need to be modified, you can log in to the console of the active device of the VAC system to modify parameters. You cannot enter global configuration mode from the console of the standby device.

Notes

- Configuration commands take effect only after the switch is restarted except the **device** *device_id* **description** *device*1 command, which takes effect immediately.

Configuration Steps

Entering the Domain Configuration Mode

- Optional.
- Run this command in VAC mode to enter the domain configuration mode. Only ACs with the same domain ID can form a VAC system. In VAC mode, you can change or configure a domain ID, device priority, and switch ID only after entering the domain configuration mode.

Command	**virtual-ac domain** *domain_id*
Parameter Description	*domain_id*: Indicates the virtual domain ID of the VAC system.
Defaults	The default domain ID is 100.
Command Mode	config-vac-domain configuration mode
Usage Guide	Only two devices with the same domain ID can compose a virtual device. The domain ID must be unique in the LAN.

Changing the Domain ID of the VAC System

- Optional.
- To change the domain ID of a device, run this command on the console of the active device in the VAC system.

Command	**device** *device_id* **domain** *new_domain_id*
Parameter Description	*device_id*: Indicates the ID of the currently running device in VAC mode. The value varies with the product model. *new_domain_id*: Indicates the changed domain ID. The value ranges from 1 to 255.
Defaults	The default value is 100.
Command Mode	config-vac-domain configuration mode
Usage Guide	This command is available only in VAC mode and the configuration takes effect only after device restart.

Changing the Device ID

- Optional.
- To change the device ID of a device, run this command on the console of the active device in the VAC system.

Command	**device** *device_id* **renumber** *new_device_id*
Parameter Description	*device_id*: Indicates the ID of the currently running device in VAC mode. The value varies with the product model. *new_device_id*: Indicates the changed device ID.
Defaults	*N/A*
Command Mode	config-vac-domain configuration mode
Usage Guide	This command is available only in VAC mode and the configuration takes effect only after device restart. This command is used only to change the device ID and will not change configuration relevant to the device ID. In VAC mode, many configurations are relevant to the device ID (for example, the type of the device installed by running the **install** command, configuration commands in various interface modes, and configuration commands using the port ID). After the device ID is changed, check whether all configuration is correct.

Changing the Device Priority

- Optional.
- To change the priority of a device, run this command on the console of the active device in the VAC system.
- A larger value indicates a higher priority. The device with a higher priority is elected as the active device.

Command	**device** *device_id* **priority** *priority_num*
Parameter Description	*device_id*: Indicates the ID of the device with the priority to be configured. *priority_num*: Indicates the device priority. The value ranges from 1 to 255.
Defaults	The default priority is 100.
Command Mode	config-vac-domain configuration mode
Usage Guide	A larger value indicates a higher priority. The device with a higher priority is elected as the active device. This command is available in both the standalone mode and VAC mode. The changed priority takes effect only after the device restart. This command will not change the device ID. In standalone mode, if *device_id* is set to 1 but the **device 2 priority 200** command is executed, the command does not take effect unless device_id is changed to 2 and the command is executed again. In VAC mode, *device_id* indicates the ID of the currently running device. If the device ID does not exist, the priority configuration does not take effect.

Configuring the Device Alias

- Optional.
- To configure an alias for a device, run this command on the console of the active device in the VAC system.
- Run the **device** device_*id* **description** *device1* command to configure the device alias. The device alias can contain a maximum of 32 characters.

Command	**device device**_*id* **description** *dev-name*
Parameter	*device_id*: Indicates the ID of the device with the priority to be configured.

Description	*dev_name*: Indicates the device name.
Defaults	*N/A*
Command Mode	config-vac-domain configuration mode
Usage Guide	This command is available in both the standalone mode and VAC mode. The configuration takes effect immediately in VAC mode.

Configuring the ID of the Switch Connected to a Device

- Optional.
- To configure the ID of the switch connected to a device, run this command on the console of the active device in the VAC system.
- Run the **device** *device_id* **connect_switch** *switch_id* command to configure the ID of the switch connected to a device. The value ranges from 1 to 255.

Command	**device** *device_id* **connect_switch** *switch_id*
Parameter Description	*device_id*: Indicates the ID of the device with the priority to be configured. switch_id: Indicates the ID of the switch connected to the device.
Defaults	N/A
Command Mode	config-vac-domain configuration mode
Usage Guide	Set the ID of the connected switch. If the specified switch ID is different from that of the active device, the device will be preferentially elected as the standby device. This command is available in both the standalone mode and VAC mode. The changed switch ID takes effect only after device restart. In VAC mode, *device_id* indicates the ID of the currently running device. If the device ID does not exist, the configuration does not take effect.

Saving the Configuration File

Run the **exit** command to exit the VAC configuration mode and run the **write** command to save the configuration to the **config_vac.dat** file.

Verification

Run the **show virtual-ac** [**topology | config**] command to display information about the currently running VAC system, topology structure, or VAC system parameters.

Command	**show virtual-ac** [**topology	config**]
Parameter Description	Topology: Indicates the topology information, that is, VAC system configuration information.
Command Mode	Privileged EXEC mode
Usage Guide	Check the domain ID and the device ID, status, and role of each device.

Configuration Example

Configuring VAC System Attributes

Scenario **Figure 4-12**	 AC 1 and AC 2 form a VAC system. Change the device ID of AC 2 to 3 and priority to 150. Assume that AC 1 is the global active device. Complete the configuration on the global active device.
Configuration Steps	● Modify the configuration of AC 2.
AC 2	Ruijie#config Ruijie(config)# virtual-ac domain 100 Ruijie(config-vac-domain)# device 2 renumber 3 Ruijie(config-vac-domain)# device 2 priority 150 Ruijie(config-vac-domain)# device 2 description AC3
Verification	● Run the **show virtual-ac config** command to display the configuration.
AC 1	Ruijie#show virtual-ac config device_id: 1 (mac: 0x1201aeda0M) ! virtual-ac domain 100 ! device 1 device 1 priority 100 ! device convert mode virtual ! port-member interface GigabitEthernet 0/1 ! port-member interface GigabitEthernet 0/2 !
	device_id: 3 (mac: 0x1201aeda0E) ! virtual-ac domain 100

	! device 3 device 3 priority 150 ! device convert mode virtual ! port-member interface GigabitEthernet 1/1 ! port-member interface GigabitEthernet 1/2 ! device 3 description AC3 !

4.4.2.2 Configuring Heartbeat Links

Configuration Effect

- After devices compose a VAC system or when the VAC system is running, if common ports need to be switched to heartbeat ports and vice versa, you can log in to the console of the active device in the VAC system for modification. You cannot enter the global configuration mode from the console of the standby device.

Notes

- You can log in to the console of the VAC system via a serial port or in telnet mode, to add or delete heartbeat ports.

Configuration Steps

Entering the Heartbeat Port Mode

- Run the **vac-port** command to enter the heartbeat port configuration mode. This command is optional.
- When the device enters the heartbeat port configuration mode, you can add or delete heartbeat ports.

Command	**vac-port**
Parameter Description	N/A
Defaults	N/A
Command Mode	Configuration mode
Usage Guide	This command is available in both the standalone mode and VAC mode.

Configuring Heartbeat Ports

- Run the **port-member interface** *interface-name* [**copper** | **fiber**] command to configure a heartbeat port. This command is optional.
- Run the **port-member interface** command to add or delete a heartbeat port.

Command	**port-member interface** *interface-name* [**copper | fiber**]
Parameter Description	*interface-name*: Indicates a 2D port name, for example, GigabitEthernet 0/1 and GigabitEthernet 0/3. **copper**: Indicates the electrical port attribute. **fiber**: Indicates the SFP port attribute.
Defaults	N/A
Command Mode	config-vac-port configuration mode
Usage Guide	This command is available in both VAC mode and standalone mode. In standalone mode, the command configuration needs to be saved and the device where the heartbeat member port resides needs to be restarted for the configuration to take effect. In VAC mode, the command configuration takes effect immediately.

The configured heartbeat member links take effect immediately during the running of the VAC system. Heartbeat ports need to be configured on all devices.

To prevent loops from being instantaneously generated when a heartbeat port is switched to a common port, the system automatically sets the port to be in the shutdown state when this command is executed. You can reconnect the link and run the **no shutdown** command to enable the port.

If the VAC system topology is split because a heartbeat port is switched to a common port, the heartbeat port cannot be deleted. You can disconnect the physical port and then delete the heartbeat port.

Verification

Run the **show virtual-ac link** [**port**] command to display the running status of the current heartbeat port.

Command	**show virtual-ac link** [**port**]
Parameter Description	**port**: Displays information about a specific port.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

Configuring Heartbeat Links

Scenario **Figure 4-13**	Configuration Steps	● Add Port 1/0/3 as a heartbeat port and remove the heartbeat port 0/2.
	Ruijie#config Ruijie(config)# vac-port Ruijie(config-vac-port)# port-member interface Gigabitethernet 1/0/3 Ruijie(config-vac-port)# no port-member interface Gigabitethernet 1/0/2
Verification	● Run the **show virtual-ac config** command to display heartbeat links. Assume that device-1 is the active device. Run the command on the active device.
	Ruijie#show virtual-ac config device_id: 1 (mac: 0x1201aeda0M) ! Virtual-ac domain 100 ! device 1 device 1 priority 200 ! device convert mode virtual ! port-member interface Gigabitethernet 0/1 ! port-member interface Gigabitethernet 0/3 !
	device_id: 2 (mac: 0x1201aeda0E) ! virtual-ac domain 100 ! device 2 device 2 priority 100 ! device convert mode virtual !

	port-member interface Gigabitethernet 0/1 ! port-member interface Gigabitethernet 0/2 !

4.4.2.3 Configuring Dual-active Detection

Configuration Effect

Configure the relevant detection mechanism to prevent coexistence of dual active devices.

Notes

- Dual-active detection can be configured only in VAC mode.
- Dual-active detection is configured in global configuration mode and the dual-active detection configuration takes effect immediately on the active device. Run the **show running-config** command to display the configuration.
- BFD-based dual-active detection configuration cannot be displayed by running the BFD display command but by running the dual-active detection display command.

Configuration Steps

Configuring BFD-based Dual-active Detection

- In BFD-based dual-active detection, a direct link needs to be established between two chassis and the ports at both ends of the link must be physical routing ports. The following configuration is required on both devices.
- Enter the interface configuration mode of the detection port and configure the detection port as a routing port.
- Exit the interface configuration mode, and run the **virtual-ac domain** *domain_id* command to enter the config-vac-domain configuration mode.
- In config-vac-domain configuration mode, run the **dual-active detection bfd** command to enable the BFD function. This command is optional. Use this command when you need to configure BFD-based dual-active detection.
- In config-vac-domain mode, run the **dual-active bfd interface** *interface-name* command to configure the BFD detection port. This command is optional. When configuring the BFD-based dual-active detection, use this command to configure the BFD detection port.
- If no BFD detection port is available after a BFD detection port is deleted, the BFD detection will be unavailable.

Command	**virtual-ac domain** *domain_id*
Parameter Description	*domain_id*: Indicates the virtual domain ID of the VAC system.
Defaults	The default domain ID is 100.
Command Mode	config-vac-domain configuration mode
Usage Guide	Only two devices with the same domain ID can compose a virtual device. The domain ID must be unique in the LAN.

Command	**dual-active detection** { **aggregateport	bfd** }
Parameter Description	**aggregateport**: Specifies the aggregate port-based detection. **bfd**: Indicates BFD detection.
Defaults	The dual-active detection function is disabled.
Command Mode	config-vac-domain configuration mode
Usage Guide	This command can be configured only in VAC mode.

Command	**dual-active bfd interface** *interface-name*
Parameter Description	*interface-name*: Indicates the type and ID of the detection port.
Defaults	*N/A*
Command Mode	config-vac-domain configuration mode
Usage Guide	BFD detection ports must be routing ports and reside in different devices.

- BFD detection ports must be direct physical routing ports and must reside in different devices.
- The configured port type is unlimited. Dual-active detection links are used to transmit only BFD packets, and the traffic is light. Therefore, it is recommended to configure a 1000M or 100M port as the dual-active detection port.
- After a Layer-3 routing port configured for dual-active detection is switched into a Layer-2 switching port (by running the **switchport** command on the port), the BFD dual-active detection configuration is automatically cleared.
- It is recommended to adopt direct connection for the BFD link and the BFD link connects only the active and standby devices.
- When a dual-active conflict is detected and one VAC system is enabled to enter the recovery state, users can rectify the fault by eliminating the VSL failure rather than by directly resetting the VAC system in the recovery state. Otherwise, a dual-active conflict will be incurred in the network.

Configuring Aggregate Port-based Dual-active Detection

- To configure aggregate port-based dual-active detection, configure an aggregate port AP and then specify the aggregate port AP as the detection port.
- Run the **port-group** *ap-num* command to add a physical member port to the aggregate port AP.
- Run the **dual-active interface** *interface-name* command to configure the aggregate port as the dual-active detection port. This command is optional. When configuring aggregate port-based dual-active detection, use this command to configure the aggregate port as the dual-active detection port.

- Run the **dad relay enable** command to enable the function of transferring dual-active detection packets on ports in the upstream and downstream devices. This command is optional. When configuring aggregate port-based dual-active detection, use this command to forward DAD packets (that is, dual-active detection packets).
- Disabling the aggregate port-based dual-active detection will invalidate the dual-active detection of the aggregate port.
- If no detection port is available after a detection port is deleted, the detection will be unavailable.
- The function of forwarding aggregate port-based dual-active detection packets is disabled by default.

Command	**virtual-ac domain** *domain_id*
Parameter Description	*domain_id*: Indicates the virtual domain ID of the VAC system.
Defaults	The default domain ID is 100.
Command Mode	config-vac-domain configuration mode
Usage Guide	Only two devices with the same domain ID can compose a virtual device. The domain ID must be unique in the LAN.

Command	**dual-active interface** *interface-name*
Parameter Description	*interface-name*: Indicates the type and ID of the detection port.
Defaults	*N/A*
Command Mode	config-vac-domain configuration mode
Usage Guide	Detection ports must belong to an aggregate port and member ports of the aggregate port must reside in different devices.

It is recommended that physical ports that are added to an aggregate detection port reside in different devices.

When a dual-active conflict is detected and one VAC system is enabled to enter the recovery state, users can rectify the fault by eliminating the heartbeat link failure rather than by directly resetting the VAC system in the recovery state. Otherwise, a dual-active conflict will be incurred in the network.

Configuring Excluded Port List in Recovery Mode

- When dual active devices are detected, one active device must enter the recovery mode. In recovery mode, all service ports of the device need to be disabled. To ensure normal use of service ports for some special purposes (for example, configuring a port for logging in to the management device remotely), users can configure some ports as excluded ports that do not need to be disabled in recovery mode.
- After entering the config-vac-domain configuration mode, run the **dual-active exclude interface** *interface-name* command to specify excluded ports that do not need to be disabled in recovery mode. This command is optional.

Command	**dual-active exclude interface** *interface-name*

Parameter Description	*interface-name*: Indicates the type and ID of a port.
Defaults	*N/A*
Command Mode	config-vac-domain configuration mode
Usage Guide	This command can be configured only in VAC mode. Excluded ports must be routing ports and cannot be heartbeat ports. You can configure multiple excluded ports.

Excluded ports must be routing ports and cannot be heartbeat ports.

After a routing port is switched into a switching port (run the **switchport** command on the port), the excluded port configuration associated with the routing port is automatically cleared.

Verification

Run the **show virtual-ac dual-active summary** command to display the current dual-active configuration.

Command	**show virtual-ac dual-active summary**
Parameter Description	**smmary**: Displays the DAD summary.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

Configuring BFD-based Dual-active Detection

Scenario Figure 4-14	 ● Device 1 and Device 2 compose a VAC system (the domain ID is 100). The priority of Device 1 is 200 and the priority of Device 2 is 150. A connection is established between Port Gi1/0/1 of Device 1 and Port Gi2/0/1 of Device 2, which forms the VSL between Device 1 and Device 2. Port Gi1/0/2 of Device 1 is connected to Port G2/0/2 of Device 2. Ports G1/0/2 and G2/0/2 are both routing ports. ● Ports G1/0/2 and G2/0/2 are a pair of BFD dual-active detection ports.
Configuration Steps	● Configure Port G1/0/2 and Port G2/0/2 as routing ports. ● Enable the BFD-based dual-active detection. ● Configure Port G1/0/2 and Port G2/0/2 as BFD detection ports. Device 1 and Device 2 form a VAC system. Therefore, the configuration above can be performed on either Device 1 or Device 2. Here uses Device 1 as an example.

Switch 1	Ruijie(config)# interface GigabitEthernet 1/0/2 Ruijie(config-if-GigabitEthernet 1/0/2)# no switchport Ruijie(config)# interface GigabitEthernet 2/0/2 Ruijie(config-if-GigabitEthernet 2/0/2)# no switchport Ruijie(config-if)# virtual-ac domain 100 Ruijie(config-vac-domain)# dual-active detection bfd Ruijie(config-vac-domain)# dual-active bfd interface GigabitEthernet 1/0/2 Ruijie(config-vac-domain)# dual-active bfd interface GigabitEthernet 2/0/2
Verification	● Check the status of the dual-active detection function. ● Check the BFD-based dual-active detection configuration.
Switch 1	Ruijie# show switch virtual dual-active summary BFD dual-active detection enabled: Yes Aggregateport dual-active detection enabled: No Interfaces excluded from shutdown in recovery mode: In dual-active recovery mode: NO Ruijie# show switch virtual dual-active bfd BFD dual-active detection enabled: Yes BFD dual-active interface configured: GigabitEthernet 1/0/2: UP GigabitEthernet 2/0/2: UP

Common Errors

- A BFD detection port is not a routing port.
- Both BFD-based dual-active detection and aggregate port-based dual-active detection are activated.

Configuring Aggregate Port-based Dual-active Detection

Scenario **Figure 4-15**	 ● AC 1, AC 2, AC 3, and AC 4 form a VAC system (the domain ID is 1). The priority of AC 1 is 200, and the priorities of AC 2, AC 3, and AC4 are all 150. Ports Gi1/0/1, Gi2/0/1, Gi3/0/1, and Gi4/0/1 of the VAC system establish connections to the Layer-2 switch, which form the heartbeat links of the VAC system. Ports G0/1, G0/2, G0/3, and G0/4 of the upstream device are respectively connected to Ports G1/0/2, G2/0/2, G3/0/2, and G4/0/2 of the VAC system to form an aggregate port group that covers four member links. The ID of the aggregate port group is 1. All members of Aggregate Port Group 1 are GE SFP ports.
Configuration Steps	● Configure Aggregate Port Group 1 as the dual-active detection port.
AC 1	`Ruijie(config)# virtual-ac domain 100` `Ruijie(c config-vs-domain)# dual-active detection aggregateport` `Ruijie(config-vac-domain)# dual-active interface aggregateport 1`
Layer-2 Switch	`Ruijie# configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.` `Ruijie(config)#interface  aggregateport 1` `Ruijie(config-if-AggregatePort 1)#dad relay enable`
Verification	● Check the status of the dual-active detection function.
AC 1	`Ruijie#show virtual-ac dual-active summary` `BFD dual-active detection enabled: No` `Aggregateport dual-active detection enabled: Yes` `Interfaces excluded from shutdown in recovery mode:` `In dual-active recovery mode: No`

	Ruijie#show virtual-ac dual-active aggregateport Aggregateport dual-active detection enabled: Yes Aggregateport dual-active interface configured: AggregatePort 1: UP GigabitEthernet 1/0/2: UP GigabitEthernet 2/0/2: UP GigabitEthernet 3/0/2: UP GigabitEthernet 4/0/2: UP

Common Errors

- A dual-active detection port is not an aggregate port.

4.4.2.4 Configuring Standby Device Preemption

Configuration Effect

Configure standby device preemption to reduce the cases that the active and standby devices are faulty simultaneously.

Notes

- The standby device preemption can be configured only in VAC mode.
- Standby device preemption is configured in global configuration mode and the configuration takes effect immediately on the active device. Run the **show running-config** command to display the configuration.

Configuration Steps

Configuring Standby Device Preemption

Configuration Steps	• Configure standby device preemption.
AC 1	Ruijie(config)# virtual-ac domain 100 Ruijie(config-vs-domain)# slave preemptive enable
Verification	• Check the status of the dual-active detection function.
AC 1	Ruijie#show running-config virtual-ac domain 100 slave preemptive enable

4.5 Monitoring

Displaying

Description	Command

Displays information about the currently running VAC system, topology structure, or current VAC system parameters.	**show virtual-ac** [**topology | config | role**]
Displays the current dual-active detection configuration.	**show virtual-ac dual-active summary**
Displays the heartbeat link running status in VAC mode.	**show virtual-ac link** [**port**]
Redirects to the console of the active device or any device.	**session** { **device** *device_id* | **master** }
Displays the device ID.	**show device id**

5 Configuring Bonjour Gateway

5.1 Overview

The Bonjour gateway is used to manage the clients and servers supporting the Bonjour protocol, to implement Bonjour applications in large-scale networks.

The Bonjour gateway provides the following functions:

- Controls the traffic of mDNS packets in the network to decrease excessive mDNS packets.
- Configures Bonjour policies and rules to manage the available services on the client.
- Forwards the mDNS packets of clients and servers across VLANs to enhance ease of use for networks.

Protocols and Standards

- RFC 1034: Domain Names - Concepts and Facilities
- RFC 1035: Domain Names - Implementation and Specification
- RFC 6762: Multicast DNS

5.2 Applications

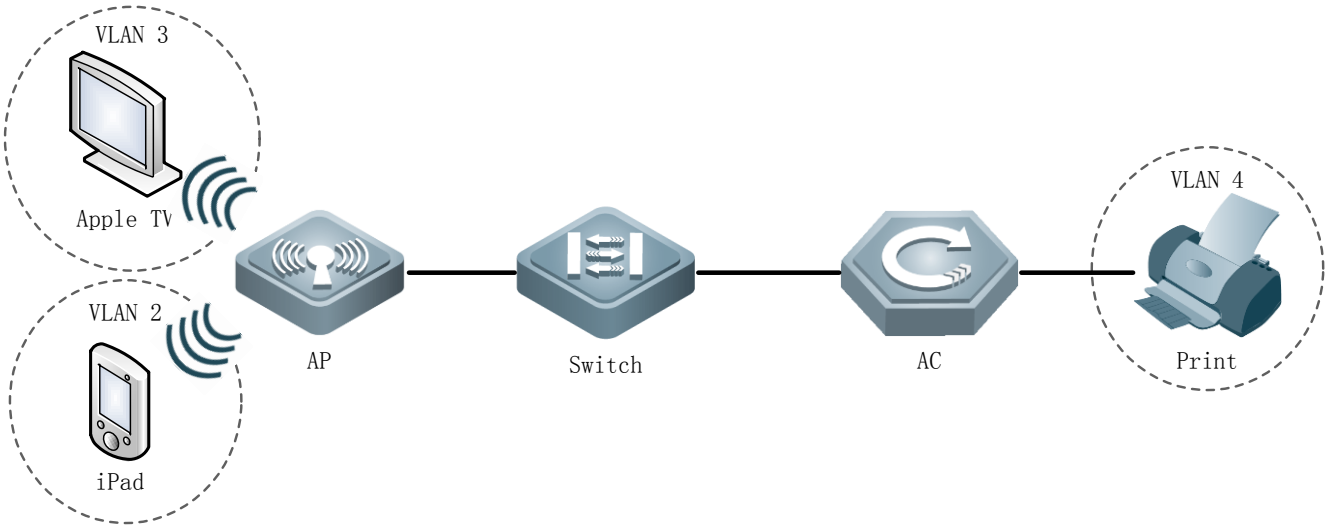
Application	Description
Query Proxy and Response Forwarding	In some cases, the Bonjour gateway receives query packets from a client, but its service resource entries show that it does not obtain the specified service requested by the client. In this case, the Bonjour gateway needs to perform query proxy and response forwarding on the specified service. When the Bonjour gateway forwards the query packets and receives response packets about the service, it adds information about the service to the Bonjour service resource entries, and forwards the response packets to the client. Then, the Bonjour gateway can perform response proxy for the server.

5.2.1 Query Proxy and Response Forwarding

Scenario

As shown in the following figure, iPad, Apple TV, and Print are located in different VLANs. iPad needs to obtain the IP addresses of Apple TV and Print through the Bonjour gateway to communicate with them.

Figure 5-1 Bonjour Gateway Topology



Deployment

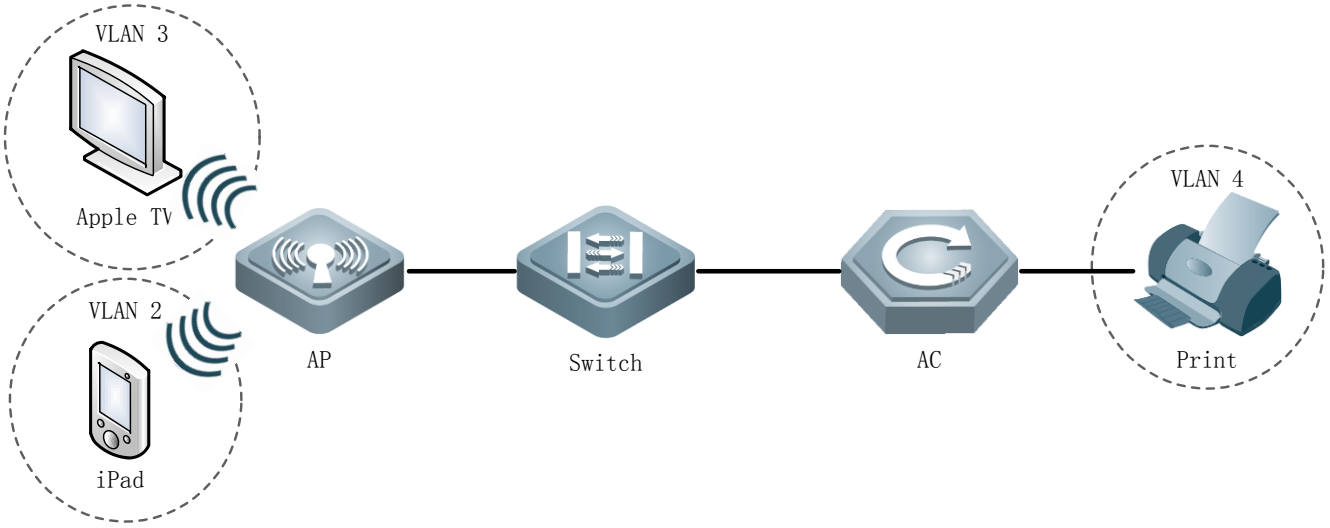
- Enable the Bonjour gateway globally to process the multicast DNS request packets received on the interface.

5.2.2 Preemption Prohibition of the Multimedia Gateway

Scenario

As shown in the following figure, iPad, Apple TV, and Print are located in different VLANs. iPad needs to obtain the IP addresses of Apple TV and Print through the Bonjour gateway to communicate with them. When different clients use the screen projection function of Apple TV at the same time, they may preempt the function if the Bonjour gateway is not enabled. When the Bonjour gateway is enabled, preemption prohibition can be implemented.

Figure 5-2 Bonjour Gateway Topology



Deployment

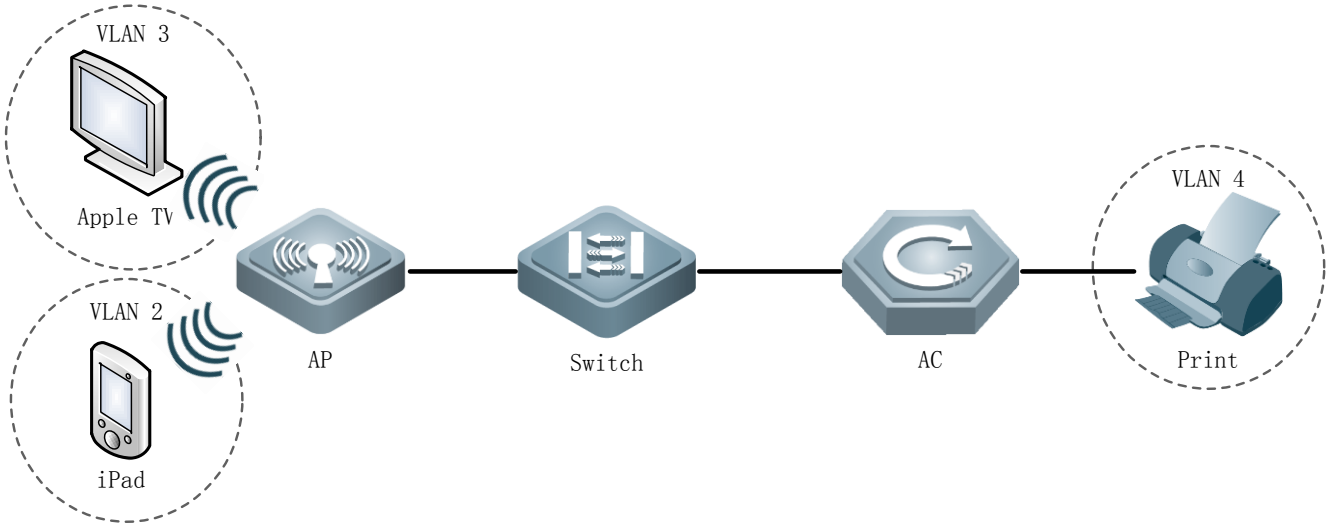
- Enable the Bonjour gateway globally to process the multicast DNS request packets received on the interface and enable preemption prohibition. Preemption prohibition is forcedly enabled, and cannot be disabled.

5.2.3 Automatic Server Renaming of the Multimedia Gateway

Scenario

As shown in the following figure, iPad, Apple TV, and Print are located in different VLANs. iPad needs to obtain the IP addresses of Apple TV and Print through the Bonjour gateway to communicate with them. If multiple Apple TVs exist in the network, the same name may be displayed for the projectors on the clients. This function enables automatic server renaming in the form of name + IP address to differentiate them.

Figure 5-3 Bonjour Gateway Topology



Deployment

- Enable the Bonjour gateway globally to process the multicast DNS request packets received on the interface and automatically rename the discovered servers.

5.3 Features

Basic Concepts

Bonjour

Bonjour is the name of the multicast DNS–based open zero-configuration network standard given by Apple. Devices using Bonjour automatically transmit their own service information in the network and listen to service information of other devices, just like saying hello to each other. In this way, Bonjour makes the systems and services in a LAN easily found even if there

is no network administrator. Bonjour displays the names of devices and applications supporting the multicast domain name protocol in a LAN, and uses the multicast DNS to eliminate device naming conflicts.

Bonjour Gateway

The Bonjour gateway is used to manage the clients and servers supporting the Bonjour protocol, to implement Bonjour applications in large-scale networks.

Overview

Feature	Description
Bonjour Gateway	The Bonjour gateway is used to manage the clients and servers supporting the Bonjour protocol, to implement Bonjour applications in large-scale networks.

5.3.1 Bonjour Gateway

Working Principle

The Bonjour gateway is used to manage the clients and servers supporting the Bonjour protocol, to implement Bonjour applications in large-scale networks.

The Bonjour gateway provides the following functions:

Response Proxy

Servers send Bonjour response packets in the network to advertise the services they support. After receiving the response packets, the Bonjour gateway establishes Bonjour service resource entries, and directly sends response packets to the clients that query services contained in the entries.

Query Proxy and Response Forwarding

In some cases, the Bonjour gateway receives query packets from a client, but its service resource entries show that it does not obtain the specified service requested by the client. In this case, the Bonjour gateway needs to perform query proxy and response forwarding on the specified service. When the Bonjour gateway forwards the query packets and receives response packets about the service, it adds information about the service to the Bonjour service resource entries, and forwards the response packets to the client. Then, the Bonjour gateway can perform response proxy for the server.

Screen Preemption Prohibition

When different clients use the screen projection function of Apple TV at the same time, they may preempt the function if the Bonjour gateway is not enabled. When the Bonjour gateway is enabled, preemption prohibition can be implemented.

Automatic Renaming of Servers

If multiple Apple TVs exist in the network, the same name may be displayed for the projectors on the clients. This function enables automatic server renaming in the form of name + IP address to differentiate them.

5.4 Configuration

Configuration	Description and Command	
Enabling the Bonjour Gateway	⚠ Mandatory. It is used to create the Bonjour gateway service.	
	bonjour-gateway enable	Enables the Bonjour gateway.
	⚠ Optional.	
Configuring Bonjour Policies and Rules	⚠ Optional.	
	bonjour-gateway global-strategy	Applies a specified Bonjour policy globally.
	bonjour-gateway strategy	Applies a specified Bonjour policy on interfaces.
	bonjour-gateway strategy-mode	Creates a Bonjour policy.
	service type	Configures a service rule.
	service vlan range	Configures a VLAN that allows forwarding query and response packets.
	service wired/wireless	Enables service discovery in wired or wireless mode.
Configuring Preemption Prohibition and Automatic Renaming	**bonjour-gateway airplay-preemption disable**	Disables preemption prohibition.
	bonjour-gateway airplay-rename disable	Disables automatic renaming.
Actively Querying Bonjour Services	⚠ Optional.	
	bonjour-gateway query enable	Enables the active query of Bonjour services.
	bonjour-gateway query interval	Configures the interval for actively querying Bonjour services.

5.4.1 Enabling the Bonjour Gateway

Configuration Effect

- Implement Bonjour applications in large-scale networks after enabling the Bonjour gateway.

Notes

- The Bonjour gateway must be enabled on Layer-3 interfaces.

Configuration Steps

↘ **Enabling the Bonjour Gateway**

- Mandatory.

Command	**bonjour-gateway enable**
Parameter Description	N/A
Defaults	The Bonjour gateway is disabled by default.
Command Mode	Global configuration mode/Interface configuration mode
Usage Guide	After this function is configured, multicast is enabled on all or specified Layer-3 interfaces to forward multicast packets. The global Bonjour gateway must be enabled before enabling Bonjour gateway on a specified interface.

Configuring the Threshold of Multicasting Response Packets

- Optional.
- Run the **bonjour-gateway multicast** command to configure the threshold of multicasting response packets.

Command	**bonjour-gateway multicast** *number*
Parameter Description	*number*: Sets the threshold of multicasting response packets. The value ranges from **1** to **64**.
Defaults	The threshold of multicasting response packets is **10** by default.
Command Mode	Global configuration mode
Usage Guide	The **bonjour-gateway multicast** command is used to configure the threshold of multicasting response packets. The **no bonjour-gateway multicast** command is used to restore the default settings. By default, the threshold of multicasting response packets is **10**.

Verification

- Run the **show run** command to display the Bonjour gateway configurations.

Configuration Example

Enabling the Bonjour Gateway

Scenario Figure 5-4	iPad, Apple TV, and Print are located in different VLANs. iPad needs to obtain the IP addresses of Apple TV and Print through the Bonjour gateway to communicate with them.

	Configuration Steps	● Enable the Bonjour gateway.
	`Ruijie#configure terminal` `Ruijie(config)#` `Ruijie(config)#interface vlan 2` `Ruijie(config-if-vlan 2 )#bonjour-gateway enable`
Verification	● Check whether the Bonjour gateway is enabled. `Ruijie#show run | begin interface vlan 2` `Current configuration : 491 bytes` `interface vlan 2` ` bonjour-gateway enable` `!`

5.4.2 Configuring Bonjour Policies and Rules

Configuration Effect

- Configure Bonjour policies and rules to manage the available services on the client.

Configuration Steps

↘ Creating a Bonjour Policy

- Optional.
- Run the **bonjour-gateway strategy-mode** command to create a Bonjour policy.

Command	**bonjour-gateway strategy-mode** *name*
Parameter Description	*name*: Indicates the name of a Bonjour policy.
Defaults	No Bonjour policy is created by default.

Command Mode	Global configuration mode
Usage Guide	The **bonjour-gateway strategy-mode** command is used to create a Bonjour policy. The **no bonjour-gateway strategy-mode** command is used to delete a Bonjour policy. By default, no Bonjour policy is created. A maximum of 1000 Bonjour policies can be created on the device.

Configuring a Service Discovery Rule

- Optional.
- Run the **service [wired | wireless] disable** command to configure a service discovery rule.

Command	**service [wired | wireless] disable**
Parameter Description	N/A
Defaults	Services can be discovered in both wired and wireless modes by default.
Command Mode	Bonjour gateway mode
Usage Guide	The **service [wired | wireless] disable** command is used to configure a service discovery rule. The **no service [wired | wireless] disable** command is used to delete a service discovery rule. By default, service discovery is allowed in both wired and wireless modes.

Configuring a Service Instance

- Optional.
- Run the **service type** command to set a service rule.

Command	**service type** *type* **[instance** *name* | **disable]**
Parameter Description	*type*: Indicates the type of a service that can be found by the client. *name*: Indicate the instance name of a service that needs to be searched for by the client.
Defaults	The client can find all services by default.
Command Mode	Bonjour gateway mode
Usage Guide	The **service type** command is used to set a service rule. The **no service type** command is used to delete a service rule. By default, the client can find all services. After the **no service type** command is configured, the corresponding service cannot be found.

Configuring a Service VLAN

- Optional.
- Run the **service vlan range** command to configure a VLAN that allows forwarding query and response packets when a specified Bonjour policy is applied.

Command	**service vlan** range *vlan-id-list* **[access-vlan]**
Parameter Description	*vlan-id-list*: Indicates the VLAN list. **access-vlan**: Allows forwarding query and response packets in the client-accessed VLAN.

Defaults	All query and response packets are forwarded by default.
Command Mode	Bonjour gateway mode
Usage Guide	The **service vlan range** command is used to configure a VLAN that allows forwarding query and response packets, and discard the query and response packets outside the VLAN. The **no service vlan** command is used to delete the settings. By default, all query and response packets are forwarded.

Applying a Specified Bonjour Policy Globally

- Optional.
- Run the **bonjour-gateway global-strategy** command to apply a specified Bonjour policy globally.

Command	**bonjour-gateway global-strategy** *name*
Parameter Description	*name*: Indicates the name of a Bonjour policy.
Defaults	No Bonjour policy is applied globally by default.
Command Mode	Configuration mode
Usage Guide	The **bonjour-gateway global-strategy** command is used to apply a specified Bonjour policy globally. The **no bonjour-gateway global-strategy** command is used to cancel the applied Bonjour policy. By default, no Bonjour policy is applied globally. That is, when the Bonjour gateway is enabled, only the default service type is supported by default, and services can be found in both wired and wireless modes.

Applying a Specified Bonjour Policy

- Optional.
- Run the **bonjour-gateway strategy** command to apply a specified Bonjour policy on Layer-3 interfaces.

Command	**bonjour-gateway strategy** *name*
Parameter Description	*name*: Indicates the name of a Bonjour policy.
Defaults	No Bonjour policy is applied on Layer-3 interfaces by default.
Command Mode	Interface configuration mode
Usage Guide	The **bonjour-gateway strategy** command is used to apply a specified Bonjour policy on Layer-3 interfaces. The **no bonjour-gateway strategy** command is used to cancel the applied Bonjour policy. By default, no Bonjour policy is applied on Layer-3 interfaces.

Verification

- Run the **show run** command to display the Bonjour gateway configurations.

Configuration Example

Configuring a Bonjour Policy

Scenario	For details, refer to Figure 5-4.
Configuration Steps	Configure a Bonjour policy.
	Ruijie#configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# bonjour-gateway strategy-mode teacher Ruijie(config-bonjour-gateway)#service type ftp ip 10.0.0.5 Ruijie(config-bonjour-gateway)#service vlan range 5 Ruijie(config-bonjour-gateway)#service vlan access-vlan Ruijie(config-bonjour-gateway)#exit Ruijie(config)# Ruijie(config)#interface vlan 2 Ruijie(config-if-vlan 1)#bonjour-gateway enable Ruijie(config-if-vlan 1)# bonjour-gateway strategy teacher
Verification	● Check whether the Bonjour gateway is enabled. Ruijie#show run | begin interface VLAN 1 Current configuration : 491 bytes interface VLAN 2 bonjour-gateway enable bonjour-gateway strategy teacher ! ● Check whether a Bonjour policy is configured. Ruijie#show run | begin bonjour-gateway Current configuration : 491 bytes bonjour-gateway strategy-mode teacher service type ftp ip 10.0.0.5 service vlan range 5 service vlan access-vlan !

5.4.3 Configuring Preemption Prohibition and Automatic Renaming

Configuration Effect

- Configure preemption prohibition and automatic renaming.

Configuration Steps

Disabling Preemption Prohibition

- Optional.
- Run the **bonjour-gateway airplay-preemption disable** command to disable preemption prohibition.

Command	bonjour-gateway airplay-preemption disable
Parameter Description	N/A
Defaults	Preemption prohibition is enabled by default.
Command Mode	Global configuration mode
Usage Guide	The **bonjour-gateway airplay-preemption disable** command is used to disable preemption prohibition.

Disabling Automatic Renaming

- Optional.
- Run the **bonjour-gateway airplay-rename disable** command to disable automatic renaming.

Command	bonjour-gateway airplay-rename disable
Parameter Description	N/A
Defaults	Automatic renaming is enabled by default.
Command Mode	Global configuration mode
Usage Guide	The **bonjour-gateway airplay-rename disable** command is used to disable automatic renaming.

Verification

- Run the **show run** command to display the Bonjour gateway configurations.

Configuration Example

Disabling Automatic Renaming

Scenario	For details, refer to Figure 5-4.
Configuration Steps	Disable automatic renaming.
	`Ruijie#configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.` `Ruijie(config)# bonjour-gateway airplay-rename disable`

Verification	● Check whether automatic renaming is disabled. `Ruijie#show run | begin bonjour-gateway` `Current configuration : 491 bytes` `bonjour-gateway airplay-rename disable!`

Common Errors

5.4.4 Active Query of Bonjour Services

Configuration Effect

- To implement response proxy, the Bonjour gateway needs to maintain the Bonjour service resource entries. When the active query of Bonjour services is enabled, the Bonjour gateway can guarantee the real-timeliness of Bonjour service resource entries.

Configuration Steps

↘ Enabling the Active Query of Bonjour Services

- Optional.
- Run the **bonjour-gateway query enable** command to enable the active query of Bonjour services.

Command	**bonjour-gateway query enable**
Parameter Description	N/A
Defaults	The active query of Bonjour services is disabled by default.
Command Mode	Global configuration mode
Usage Guide	The **bonjour-gateway query enable** command is used to enable the active query of Bonjour services. The **no bonjour-gateway query enable** command is used to disable the active query of Bonjour services. By default, the active query of Bonjour services is disabled.

↘ Configuring the Interval for Sending Query Packets to a Discovered Service

- Optional.
- Run the **bonjour-gateway query interval** command to configure the interval for sending query packets to a discovered service.

Command	**bonjour-gateway query interval** *number*
Parameter Description	*number*: Indicates the interval for sending query packets to a discovered service in seconds. The value ranges from **5** to **600**.
Defaults	The interval for sending query packets to a discovered service is 15 seconds by default.
Command Mode	Global configuration mode

Usage Guide	The **bonjour-gateway query interval** command is used to configure the interval for sending query packets to a discovered service. The **no bonjour-gateway query interval** command is used to restore the default settings. By default, the interval for sending query packets to a discovered service is 15 seconds.

Verification

- Run the **show run** command to display the Bonjour gateway configurations.

Configuration Example

Enabling the Active Query of Bonjour Services

Scenario	For details, refer to Figure 5-4.
Configuration Steps	Enable the active query of Bonjour services.
	`Ruijie#configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.` `Ruijie(config)#bonjour-gateway query enable` `Ruijie(config)#bonjour-gateway query interval 20`
Verification	● Check whether the active query of Bonjour services is enabled. `Ruijie#show run | begin bonjour-gateway` `Current configuration : 491 bytes` `bonjour-gateway query enable` `bonjour-gateway query interval 20` `!`

5.5 Monitoring

Displaying

Description	Command
Displays information about the discovered Bonjour service.	**show bonjour-gateway service-database**
Displays information about the discovered Bonjour service of a specified IP.	**show bonjour-gateway service-database ip** *address*
Displays the Bonjour policy information.	**show bonjour-gateway strategy-mode**

Debugging

System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Description	Command
Debugs the Bonjour gateway error.	**debug bonjour error**
Debugs preemption of the Bonjour gateway.	**debug bonjour stamng**

Access Service Configuration

1. Configuring Interfaces
2. Configuring MAC Address
3. Configuring Aggregated Port
4. Configuring VLAN
5. Configuring Super VLAN
6. Configuring MSTP
7. Configuring VLAN Group
8. Configuring PPPoE-Client
9. Configuring RLDP
10. Configuring LLDP
11. Configuring DLDP

1 Configuring Interfaces

1.1 Overview

Interfaces are important in implementing data switching on network devices. Ruijie devices support two types of interfaces: physical ports and logical interfaces. A physical port is a hardware port on a device, such as the 100M Ethernet interface and gigabit Ethernet interface. A logical interface is not a hardware port on the device. A logical interface, such as the loopback interface and tunnel interface, can be associated with a physical port or independent of any physical port. For network protocols, physical ports and logical interfaces serve the same function.

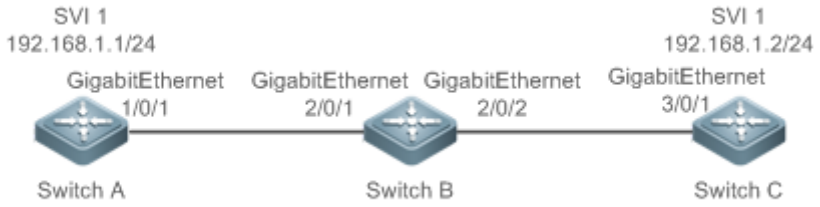
1.2 Applications

Application	Description
L2 Data Switching Through the Physical Ethernet Interface	Implement Layer-2 (L2) data communication of network devices through the physical L2 Ethernet interface.
L3 Routing Through the Physical Ethernet Interface	Implement Layer-3 (L3) data communication of network devices through the physical L3 Ethernet interface.

1.2.1 L2 Data Switching Through the Physical Ethernet Interface

Scenario

Figure 1-1



As shown in Figure 1-1 , Switch A, Switch B, and Switch C form a simple L2 data switching network.

Deployment

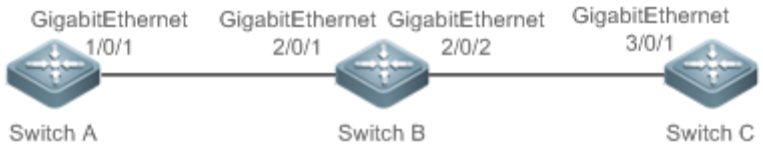
- Connect Switch A to Switch B through physical ports GigabitEthernet 1/0/1 and GigabitEthernet 2/0/1.
- Connect Switch B to Switch C through physical ports GigabitEthernet 2/0/2 and GigabitEthernet 3/0/1.
- Configure GigabitEthernet 1/0/1, GigabitEthernet 2/0/1, GigabitEthernet 2/0/2, and GigabitEthernet3/0/1 as Trunk ports.

- Create a switch virtual interface (SVI), SVI 1, on Switch A and Switch C respectively, and configure IP addresses from a network segment for the two SVIs. The IP address of SVI 1 on Switch A is 192.168.1.1/24, and the IP address of SVI 1 on Switch C is 192.168.1.2/24.
- Run the **ping 192.168.1.2** command on Switch A and the **ping 192.168.1.1** command on Switch C to implement data switching through Switch B.

1.2.2 L3 Routing Through the Physical Ethernet Interface

Scenario

Figure 1-2



As shown in Figure 1-2, Switch A, Switch B, and Switch C form a simple L3 data communication network.

Deployment

- Connect Switch A to Switch B through physical ports GigabitEthernet 1/0/1 and GigabitEthernet 2/0/1.
- Connect Switch B to Switch C through physical ports GigabitEthernet 2/0/2 and GigabitEthernet 3/0/1.
- Configure GigabitEthernet 1/0/1, GigabitEthernet 2/0/1, GigabitEthernet 2/0/2, and GigabitEthernet3/0/1 as L3 routed ports.
- Configure IP addresses from a network segment for GigabitEthernet 1/0/1 and GigabitEthernet 2/0/1. The IP address of GigabitEthernet 1/0/1 is 192.168.1.1/24, and the IP address of GigabitEthernet 2/0/1 is 192.168.1.2/24.
- Configure IP addresses from a network segment for GigabitEthernet 2/0/2 and GigabitEthernet 3/0/1. The IP address of GigabitEthernet 2/0/2 is 192.168.2.1/24, and the IP address of GigabitEthernet 3/0/1 is 192.168.2.2/24.
- Configure a static route entry on Switch C so that Switch C can directly access the network segment 192.168.1.0/24.
- Run the **ping 192.168.2.2** command on Switch A and the **ping 192.168.1.1** command on Switch C to implement L3 routing through Switch B.

1.3 Features

Basic Concepts

↘ Interface Classification

Interfaces on Ruijie devices fall into three categories:

- L2 interfaceL3 interface (supported by L3 devices)

1. Common L2 interfaces are classified into the following types:

- Switch port
- L2 aggregate port (AP)

2. Common L3 interfaces are classified into the following types:

- Routed port
- L3 AP port
- SVI
- Loopback interface
- Tunnel interface

Switch Port

A switch port is an individual physical port on the device, and implements only the L2 switching function. The switch port is used to manage physical ports and L2 protocols related to physical ports.

L2 AP Port

An AP port is formed by aggregating multiple physical ports. Multiple physical links can be bound together to form a simple logical link. This logical link is called an AP port.

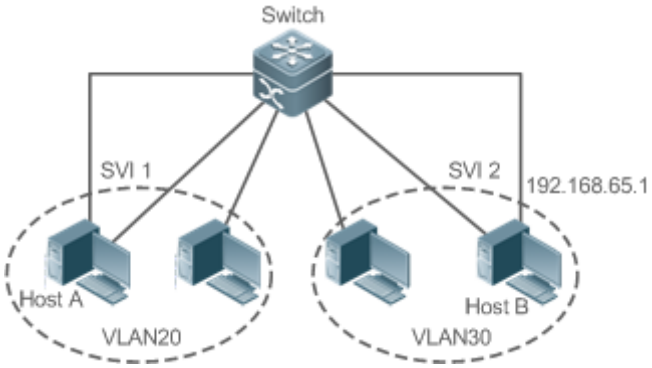
For L2 switching, an AP port is equivalent to a switch port that combines bandwidths of multiple ports, thus expanding the link bandwidth. Frames sent over the L2 AP port are balanced among the L2 AP member ports. If one member link fails, the L2 AP port automatically transfers the traffic on the faulty link to other member links, improving reliability of connections.

SVI

The SVI can be used as the management interface of the local device, through which the administrator can manage the device. You can also create an SVI as a gateway interface, which is mapped to the virtual interface of each VLAN to implement routing across VLANs among L3 devices. You can run the **interface vlan** command to create an SVI and assign an IP address to this interface to set up a route between VLANs.

As shown in Figure 1-3, hosts in VLAN 20 can directly communicate with each other without participation of L3 devices. If Host A in VLAN 20 wants to communicate with Host B in VLAN 30, SVI 1 of VLAN 20 and SVI 2 of VLAN 30 must be used.

Figure 1-3



Routed Port

A physical port on a L3 device can be configured as a routed port, which functions as the gateway interface for L3 switching. A routed port is not related with a specific VLAN. Instead, it is just an access port. The routed port cannot be used for L2 switching. You can run the **no switchport** command to change a switch port to a routed port and assign an IP address to this port to set up a route. Note that you must delete all L2 features of a switch port before running the **no switchport** command.

If a port is a L2 AP member port or a DOT1X port that is not authenticated, you cannot run the **switchport** or **no switchport** command to configure the switch port or routed port.

L3 AP Port

Like the L2 AP port, a L3 AP port is a logical port that aggregates multiple physical member ports. The aggregated ports must be the L3 ports of the same type. The AP port functions as a gateway interface for L3 switching. Multiple physical links are combined into one logical link, expanding the bandwidth of a link. Frames sent over the L3 AP port are balanced among the L3 AP member ports. If one member link fails, the L3 AP port automatically transfers the traffic on the faulty link to other member links, improving reliability of connections.

A L3 AP port cannot be used for L2 switching. You can run the **no switchport** command to change a L2 AP port that does not contain any member port into a L3 AP port, add multiple routed ports to this L3 AP port, and then assign an IP address to this L3 AP port to set up a route.

Loopback Interface

The loopback interface is a local L3 logical interface simulated by the software that is always UP. Packets sent to the loopback interface are processed on the device locally, including the route information. The IP address of the loopback interface can be used as the device ID of the Open Shortest Path First (OSPF) routing protocol, or as the source address used by Border Gateway Protocol (BGP) to set up a TCP connection. The procedure for configuring a loopback interface is similar to that for configuring an Ethernet interface, and you can treat the loopback interface as a virtual Ethernet interface.

Tunnel Interface

The Tunnel interface implements the tunnel function. Over the Tunnel interface, transmission protocols (e.g., IP) can be used to transmit packets of any protocol. Like other logical interfaces, the tunnel interface is also a virtual interface of the system. Instead of specifying any transmission protocol or load protocol, the tunnel interface provides a standard point-to-point (P2P) transmission mode. Therefore, a tunnel interface must be configured for every individual link.

Overview

Feature	Description
Interface Configuration Commands	You can configure interface-related attributes in interface configuration mode. If you enter interface configuration mode of a non-existing logical interface, the interface will be created.
Interface Description and Administrative Status	You can configure a name for an interface to identify the interface and help you remember the functions of the interface. You can also configure the administrative status of the interface.
MTU	You can configure the maximum transmission unit (MTU) of a port to limit the length of a frame that can be received or sent over this port.
Bandwidth	You can configure the bandwidth of an interface.

Feature	Description
Load Interval	You can specify the interval for load calculation of an interface.
Carrier Delay	You can configure the carrier delay of an interface to adjust the delay after which the status of an interface changes from Down to Up or from Up to Down.
Link Trap Policy	You can enable or disable the link trap function on an interface.
Interface Index Persistence	You can enable the interface index persistence function so that the interface index remains unchanged after the device is restarted.
Routed Port	You can configure a physical port on a L3 device as a routed port, which functions as the gateway interface for L3 switching.
L3 AP Port	You can configure an AP port on a L3 device as a L3 AP port, which functions as the gateway interface for L3 switching.
Selection of Interface Medium Type	You can select the medium type (fiber or copper) of a combo port as required.
Interface Speed, Duplex Mode	You can configure the speed, duplex mode, flow control mode, and auto negotiation mode of an interface.
Automatic Module Detection	If the interface speed is set to auto, the interface speed can be automatically adjusted based on the type of the inserted module.
Port Errdisable Recovery	After a port is shut down due to a violation, you can run the **errdisable recovery** command in global configuration mode to recover all the ports in errdisable state and enable these ports.

1.3.1 Interface Configuration Commands

üRun the interface command in global configuration mode to enter interface configuration mode. You can configure interface-related attributes in interface configuration mode.

Working Principle

Run the interface command in global configuration mode to enter interface configuration mode. If you enter interface configuration mode of a non-existing logical interface, the interface will be created. You can also run the interface range or interface range macro command in global configuration mode to configure the range (IDs) of interfaces. Interfaces defined in the same range must be of the same type and have the same features.

You can run the **no interface** command in global configuration mode to delete a specified logical interface.

↘ Interface Numbering Rules

In stand-alone mode, the ID of a physical port consists of two parts: slot ID and port ID on the slot. For example, if the slot ID of the port is 2, and port ID on the slot is 3, the interface ID is 2/3. In VSU or stack mode, the ID of a physical port consists of three parts: device ID, slot ID, and port ID on the slot. For example, if the device ID is 1, slot ID of the port is 2, and port ID on the slot is 3, the interface ID is 1/2/3.

The device ID ranges from 1 to the maximum number of supported member devices.

The slot number rules are as follows: The static slot ID is 0, whereas the ID of a dynamic slot (pluggable module or line card) ranges from 1 to the number of slots. Assume that you are facing the device panel. Dynamic slot are numbered from 1 sequentially from front to rear, from left to right, and from top to bottom.

The ID of a port on the slot ranges from 1 to the number of ports on the slot, and is numbered sequentially from left to right.

You can select fiber or copper as the medium of a combo port. Regardless of the medium selected, the combo port uses the same port ID.

The ID of an AP port ranges from 1 to the number of AP ports supported by the device.

The ID of an SVI is the VID of the VLAN corresponding to this SVI.

Configuring Interfaces Within a Range

You can run the **interface range** command in global configuration mode to configure multiple interfaces at a time. Attributes configured in interface configuration mode apply to all these interfaces.

The **interface range** command can be used to specify several interface ranges.

The **macro** parameter is used to configure the macro corresponding to a range. For details, see "Configuring Macros of Interface Ranges."

Ranges can be separated by commas (,).

The types of interfaces within all ranges specified in a command must be the same.

Pay attention to the format of the **range** parameter when you run the **interface range** command.

The following interface range formats are valid:

- **FastEtherne**t device/slot/{first port} - {last port};
- **GigabitEthernet** device/slot/{first port} - {last port};
- **TenGigabitEthernet** device/slot/{first port} - {last port};
- **FortyGigabitEthernet** device/slot/{first port} - {last port};
- **AggregatePort** *Aggregate-port ID* (The AP ID ranges from 1 to the maximum number of AP ports supported by the device.)
- **vlan** vlan-ID-vlan-ID (The VLAN ID ranges from 1 to 4,094.)
- **Loopback** loopback-ID (The loopback ID ranges from 1 to 2,147,483,647.)
- **Tunnel** tunnel-ID (The tunnel ID ranges from 0 to the maximum number of tunnel interfaces supported by the device minus 1.)

Interfaces in an interface range must be of the same type, namely, FastEthernet, GigabitEthernet, AggregatePort, or SVI.

Configuring Macros of Interface Ranges

You can define some macros to replace the interface ranges. Before using the **macro** parameter in the **interface range** command, you must first run the **define interface-range** command in global configuration mode to define these macros.

Run the **no define interface-range macro_name** command in global configuration mode to delete the configured macros.

1.3.2 Interface Description and Administrative Status

You can configure a name for an interface to identify the interface and help you remember the functions of the interface.

You can enter interface configuration mode to enable or disable an interface.

Working Principle

Interface Description

You can configure the name of an interface based on the purpose of the interface. For example, if you want to assign GigabitEthernet 1/1 for exclusive use by user A, you can describe the interface as "Port for User A."

Interface Administrative Status

You can configure the administrative status of an interface to disable the interface as required. If the interface is disabled, no frame will be received or sent on this interface, and the interface will loss all its functions. You can enable a disabled interface by configuring the administrative status of the interface. Two types of interface administrative status are defined: Up and Down. The administrative status of an interface is Down when the interface is disabled, and Up when the interface is enabled.

1.3.3 MTU

You can configure the MTU of a port to limit the length of a frame that can be received or sent over this port.

Working Principle

When a large amount of data is exchanged over a port, frames greater than the standard Ethernet frame may exist. This type of frame is called jumbo frame. The MTU is the length of the valid data segment in a frame. It does not include the Ethernet encapsulation overhead.

If a port receives or sends a frame with a length greater than the MTU, this frame will be discarded.

The range of MTU is from 64 to 9216 characters. By default, it is 1500 characters.

The command takes effect only on physical port and AP port.

1.3.4 Bandwidth

Working Principle

The **bandwidth** command can be configured so that some routing protocols (for example, OSPF) can calculate the route metric and the Resource Reservation Protocol (RSVP) can calculate the reserved bandwidth. Modifying the interface bandwidth will not affect the data transmission rate of the physical port.

The **bandwidth** command is a routing parameter, and does not affect the bandwidth of a physical link.

1.3.5 Load Interval

Working Principle

You can run the **load-interval** command to specify the interval for load calculation of an interface. Generally, the interval is 10s.

1.3.6 Carrier Delay

Working Principle

The carrier delay refers to the delay after which the data carrier detect (DCD) signal changes from Down to Up or from Up to Down. If the DCD status changes during the delay, the system will ignore this change to avoid negotiation at the upper data link layer. If this parameter is set to a great value, nearly every DCD change is not detected. On the contrary, if the parameter is set to 0, every DCD signal change will be detected, resulting in poor stability.

If the DCD carrier is interrupted for a long time, the carrier delay should be set to a smaller value to accelerate convergence of the topology or route. On the contrary, if the DCD carrier interruption time is shorter than the topology or route convergence time, the carrier delay should be set to a greater value to avoid topology or route flapping.

1.3.7 Link Trap Policy

You can enable or disable the link trap function on an interface.

Working Principle

When the link trap function on an interface is enabled, the Simple Network Management Protocol (SNMP) sends link traps when the link status changes on the interface.

1.3.8 Interface Index Persistence

Like the interface name, the interface index also identifies an interface. When an interface is created, the system automatically assigns a unique index to the interface. The index of an interface may change after the device is restarted. You can enable the interface index persistence function so that the interface index remains unchanged after the device is restarted.

Working Principle

After interface index persistence is enabled, the interface index remains unchanged after the device is restarted.

1.3.9 Routed Port

Working Principle

A physical port on a L3 device can be configured as a routed port, which functions as the gateway interface for L3 switching. The routed port cannot be used for L2 switching. You can run the **no switchport** command to change a switch port to a

routed port and assign an IP address to this port to set up a route. Note that you must delete all L2 features of a switch port before running the **no switchport** command.

1.3.10 L3 AP Port

Working Principle

Like a L3 routed port, you can run the **no switchport** command to change a L2 AP port into a L3 AP port on a L3 device, and then assign an IP address to this AP port to set up a route. Note that you must delete all L2 features of the AP port before running the **no switchport** command.

A L2 AP port with one or more member ports cannot be configured as a L3 AP port. Similarly, a L3 AP port with one or more member ports cannot be changed to a L2 AP port.

1.3.11 Selection of Interface Medium Type

You can select the medium type (fiber or copper) of a combo port as required.

Working Principle

You can choose either fiber or copper as the medium, but the two media cannot take effect at the same time. Once you select the medium, attributes, including the connection status, speed, duplex mode, and flow control mode, are attributes of the selected medium. If you change the medium, the interface will adopt the default settings, and you must re-configure these attributes according to requirements.

The Combo Port Supports Automatic Selection of the Medium Type

- If you enable automatic selection of the medium type, the device uses the current medium if only one medium is available.
- If both media are available, the device uses the preferred medium that is configured. By default, the preferred medium is copper. You can run the **medium-type auto-select prefer fiber** command to configure fiber as the preferred media. In automatic medium selection mode, the interface adopts the default settings of attributes, such as the speed, duplex mode, and flow control mode.

If an interface is enabled with automatic selection, its peer interface must be enabled with auto negotiation; otherwise, an error will occur.

The command takes effect only on a physical port. An AP port or SVI does not support configuration of the medium type.

The command takes effect only on a port that supports medium selection.

All ports that are configured as member ports of an AP port must have the same medium type; otherwise, they cannot be added to the AP port. The type of member ports cannot be modified. A port enabled with automatic medium selection cannot be added to an AP port.

1.3.12 Interface Speed, Duplex Mode

You can configure the interface speed, duplex mode of an Ethernet physical port or AP port.

Working Principle

Speed

Generally, the speed of an Ethernet physical port is determined through negotiation with the peer device. The negotiated speed can be any speed within the interface capability. You can also configure any speed within the interface capability for the Ethernet physical port.

When you configure the speed of an AP port, the configuration takes effect on all of its member ports. (All these member ports are Ethernet physical ports.)

Duplex Mode

- The duplex mode of an Ethernet physical port or AP port can be configured as follows:
- Set the duplex mode of the interface to full-duplex so that the interface can receive packets while sending packets.
- Set the duplex mode of the interface to half-duplex so that the interface can receive or send packets at a time.
- Set the duplex mode of the interface to auto-negotiation so that the duplex mode of the interface is determined through auto negotiation between the local interface and peer interface.
- When you configure the duplex mode of an AP port, the configuration takes effect on all of its member ports. (All these member ports are Ethernet physical ports.)

1.3.13 Automatic Module Detection

If the interface speed is set to auto, the interface speed can be automatically adjusted based on the type of the inserted module.

Working Principle

Currently, the automatic module detection function can be used to detect only the SFP and SFP+ modules. The SFP is a Gigabit module, whereas SFP+ is a 10 Gigabit module. If the inserted module is SFP, the interface works in Gigabit mode. If the inserted module is SFP+, the interface works in 10 Gigabit mode.

The automatic module detection function takes effect only when the interface speed is set to auto.

1.3.14 Port Errdisable Recovery

Some protocols support the port errdisable recovery function to ensure security and stability of the network. For example, in the port security protocol, when you enable port security and configure the maximum number of security addresses on the port, a port violation event is generated if the number of addresses learned on this port exceeds the maximum number of security addresses. Other protocols, such as the Spanning Tree Protocol (STP), DOT1X, and REUP, support the similar functions, and a violating port will be automatically shut down to ensure security.

Working Principle

After a port is shut down due to a violation, you can run the **errdisable recovery** command in global configuration mode to recovery all the ports in errdisable state and enable these ports. You can manually recover a port, or automatically recover a port at a scheduled time.

1.4 Configuration

Configuration	Description and Command	
Performing Basic Configurations	(Optional) It is used to manage interface configurations, for example, creating/deleting an interface, or configuring the interface description.	
	interface	Creates an interface and enters configuration mode of the created interface or a specified interface.
	interface range	Enters an interface range, creates these interfaces (if not created), and enters interface configuration mode.
	define interface-range	Creates a macro to specify an interface range.
	snmp-server if-index persist	Enables the interface index persistence function so that the interface index remains unchanged after the device is restarted.
	description	Configures the interface description of up to 80 characters in interface configuration mode.
	snmp trap link-status	Configures whether to send the link traps of the interface.
	shutdown	Shuts down an interface in interface configuration mode.
Configuring Interface Attributes	(Optional) It is used to configure interface attributes.	
	bandwidth	Configures the bandwidth of an interface in interface configuration mode.
	carrier-delay	Configures the carrier delay of an interface in interface configuration mode.
	load-interval	Configures the interval for load calculation of an interface.
	duplex	Configures the duplex mode of an interface.
	mtu	Configures the MTU of an interface.
	negotiation mode	Configures the auto negotiation mode of an interface.
	speed	Configures the speed of an interface.
	switchport	Configures an interface as a L2 interface in interface configuration mode. (Run the **no switchport** command to configure an interface as a L3 interface.)
	switchport protected	Configures a port as a protected port.
	errdisable recovery	Recovers a port in errdisable state in global configuration mode.

1.4.1 Performing Basic Configurations

Configuration Effect

- Create a specified logical interface and enter configuration mode of this interface, or enter configuration mode of an existing physical or logical interface.
- Create multiple specified logical interfaces and enter interface configuration mode, or enter configuration mode of multiple existing physical or logical interfaces.
- The interface indexes remain unchanged after the device is restarted.
- Configure the interface description so that users can directly learn information about the interface.
- Enable or disable the link trap function of an interface.
- Enable or disable an interface.

Notes

- The **no** form of the command can be used to delete a specified logical interface or logical interfaces in a specified range, but cannot be used to delete a physical port or physical ports in a specified range.
- The **default** form of the command can be used in interface configuration mode to restore default settings of a specified physical or logical interface, or interfaces in a specified range.

Configuration Steps

↘ Configuring a Specified Interface

- Optional.
- Run this command to create a logical interface or enter configuration mode of a physical port or an existing logical interface.

Command	**interface** *interface-type interface-number*
Parameter Description	*interface-type interface-number*: Indicates the type and number of the interface. The interface can be an Ethernet physical port, AP port, SVI, or loopback interface.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	● If a logical interface is not created yet, run this command to create this interface and enter configuration mode of this interface. ● For a physical port or an existing logical interface, run this command to enter configuration mode of this interface. ● Use the **no** form of the command to delete a specified logical interface. ● Use the **default** form of the command to restore default settings of the interface in interface configuration mode.

↘ Configuring Interfaces Within a Range

- Optional.
- Run this command to create multiple logical interfaces or enter configuration mode of multiple physical port or existing logical interfaces.

Command	**interface range** { *port-range* | **macro** *macro_name* }
Parameter Description	*port-range*: Indicates the type and ID range of interfaces. These interfaces can be Ethernet physical ports, AP ports, SVIs, or loopback interfaces. *macro_name*: Indicates the name of the interface range macro.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	• If logical interfaces are not created yet, run this command to create these interfaces and enter interface configuration mode. • For multiple physical ports or existing logical interfaces, run this command to enter interface configuration mode. • Use the **default** form of the command to restore default settings of these interfaces in interface configuration mode. • Before using a macro, run the **define interface-range** command to define the interface range as a macro name in global configuration mode, and then run the **interface range macro** *macro_name* command to apply the macro.

Configuring Interface Index Persistence

- Optional.
- Run this command when the interface indexes must remain unchanged after the device is restarted.

Command	**snmp-server if-index persist**
Parameter Description	N/A
Defaults	By default, interface index persistence is disabled.
Command Mode	Global configuration mode
Usage Guide	After this command is executed, current indexes of all interfaces will be saved, and the indexes remain unchanged after the device is restarted. You can use the **no** or **default** form of the command to disable the interface index persistence function.

Configuring the Description of an Interface

- Optional.
- Run this command to configure the description of an interface.

Command	**description** *string*
Parameter Description	*string:* Indicates a string of up to 80 characters.

Defaults	By default, no description is configured.
Command Mode	Interface configuration mode
Usage Guide	This command is used to configure the description of an interface. You can use the **no** or **default** form of the command to delete the description of an interface.-

Configuring the Link Trap Function of an Interface

- Optional.
- Run this command to obtain the link traps through SNMP.

Command	**snmp trap link-status**
Parameter Description	N/A
Defaults	By default, the link trap function is enabled.
Command Mode	Interface configuration mode
Usage Guide	This command is used to configure the link trap function on an interface. When this function is enabled, the SNMP sends link traps when the link status changes on the interface. You can use the **no** or **default** form of the command to disable the link trap function.

Configuring the Administrative Status of an Interface

- Optional.
- Run this command to enable or disable an interface.
- An interface cannot send or receive packets after it is disabled.

Command	**Shutdown**
Parameter Description	N/A
Defaults	By default, the administrative status of an interface is Up.
Command Mode	Interface configuration mode
Usage Guide	You can run the **shutdown** command to disable an interface, or the **no shutdown** command to enable an interface. In some cases, for example, when an interface is in errdisable state, you cannot run the **no shutdown** command on an interface. You can use the **no** or **default** form of the command to enable the interface.

Verification

Configuring a Specified Interface

- Run the **interface** command. If you can enter interface configuration mode, the configuration is successful.

- For a logical interface, after the **no interface** command is executed, run the **show running** or **show interfaces** command to check whether the logical interface exists. If not, the logical interface is deleted.
- After the **default interface** command is executed, run the **show running** command to check whether the default settings of the corresponding interface are restored. If yes, the operation is successful.

Configuring Interfaces Within a Range

- Run the **interface range** command. If you can enter interface configuration mode, the configuration is successful.
- After the **default interface range** command is executed, run the **show running** command to check whether the default settings of the corresponding interfaces are restored. If yes, the operation is successful.

Configuring Interface Index Persistence

- After the **snmp-server if-index persist** command is executed, run the **write** command to save the configuration, restart the device, and run the **show interface** command to check the interface index. If the index of an interface remains the same after the restart, interface index persistence is enabled.

Configuring the Link Trap Function of an Interface

- Remove and then insert the network cable on a physical port, and enable the SNMP server. If the SNMP server receives link traps, the link trap function is enabled.
- Run the **no** form of the **snmp trap link-status** command. Remove and then insert the network cable on a physical port. If the SNMP server does not receive link traps, the link trap function is disabled.

Configuring the Administrative Status of an Interface

- Insert the network cable on a physical port, enable the port, and run the **shutdown** command on this port. If the syslog is displayed on the Console indicating that the state of the port changes to Down, and the indicator on the port is off, the port is disabled. Run the **show interfaces** command, and verify that the interface state changes to Administratively Down. Then, run the **no shutdown** command to enable the port. If the syslog is displayed on the Console indicating that the state of the port changes to Up, and the indicator on the port is on, the port is enabled.

Configuration Example

Configuring Basic Attributes of Interfaces

Scenario **Figure 1-4**	Configuration Steps	• Connect two devices through the switch ports. • Configure an SVI respectively on two devices, and assign IP addresses from a network segment to the two SVIs.

	● Enable interface index persistence on the two devices. ● Enable the link trap function on the two devices. ● Configure the interface administrative status on the two devices.
A	A# configure terminal A(config)# snmp-server if-index persist A(config)# interface vlan 1 A(config-if-VLAN 1)# ip address 192.168.1.1 255.255.255.0 A(config-if-VLAN 1)# exit A(config)# interface gigabitethernet 0/1 A(config-if-GigabitEthernet 0/1)# snmp trap link-status A(config-if-GigabitEthernet 0/1)# shutdown A(config-if-GigabitEthernet 0/1)# end A# write
B	B# configure terminal B(config)# snmp-server if-index persist B(config)# interface vlan 1 B(config-if-VLAN 1)# ip address 192.168.1.2 255.255.255.0 B(config-if-VLAN 1)# exit B(config)# interface gigabitethernet 0/1 B(config-if-GigabitEthernet 0/1)# snmp trap link-status B(config-if-GigabitEthernet 0/1)# shutdown B(config-if-GigabitEthernet 0/1)# end B# write
Verification	Perform verification on Switch A and Switch B as follows: ● Run the **shutdown** command on port GigabitEthern 0/1, and check whether GigabitEthern 0/1 and SVI 1 are Down. ● Run the **shutdown** command on port GigabitEthern 0/1, and check whether a trap indicating that this interface is Down is sent. ● Restart the device, and check whether the index of GigabitEthern 0/1 is the same as that before the restart.
A	A# show interfaces gigabitEthernet 0/1

1.4.2 Configuring Interface Attributes

Configuration Effect

- Enable the device to connect and communicate with other devices through the switch port or routed port.
- Adjust various interface attributes on the device.

Configuration Steps

↘ Configuring a Routed Port

- Optional.
- Run this command to configure a port as a L3 routed port.
- After a port is configured as a L3 routed port, L2 protocols running on the port do not take effect.
- This command is applicable to a L2 switch port.

Command	**no switchport**
Parameter Description	N/A
Defaults	By default, an Ethernet physical port is a L2 switch port.
Command Mode	Interface configuration mode
Usage Guide	On a L3 device, you can run this command to configure a L2 switch port as a L3 routed port. You can run the

	switchport command to change a L3 routed port into a L2 switch port.

Configuring a L3 AP Port

- Optional.
- Run the **no switchport** command in interface configuration mode to configure a L2 AP port as a L3 AP port. Run the **switchport** command to configure a L3 AP port as a L2 AP port.
- After a port is configured as a L3 routed port, L2 protocols running on the port do not take effect.
- This command is applicable to a L2 AP port.

Command	**no switchport**
Parameter Description	N/A
Defaults	By default, an AP port is a L2 AP port.
Command Mode	Interface configuration mode
Usage Guide	After entering configuration mode of a L2 AP port on a L3 device, you can run this command to configure a L2 AP port as a L3 AP port. After entering configuration mode of a L3 AP port, you can run the **switchport** command to change a L3 AP port into a L2 AP port.

Configuring the Medium Type of an Interface

- Optional.
- By default, the medium type of a combo port is copper.
- Port flapping may occur if the configured medium type of a port changes.
- This command is applicable to an Ethernet physical port or AP port.

Command	**medium-type** { **auto-select** [**prefer** [**fiber | copper**]] **| fiber | copper** }
Parameter Description	**auto-select**: Indicates that the medium type is selected automatically. **prefer** [**fiber** | **copper**]: Indicates the medium type that will be preferentially selected. **fiber**: Indicates that fiber is forcibly selected as the medium type. **copper**: Indicates that copper is forcibly selected as the medium type.
Defaults	By default, the medium type of an interface is copper.
Command Mode	Interface configuration mode
Usage Guide	Select either fiber or copper as the medium type of a port when both medium types are available. Once the medium type is selected, all interface attributes, including the status, duplex mode, and speed, are configured for the interface of the selected medium type. If the interface type is changed, the attributes of the new interface type are the default attributes. You can reconfigure these attributes as required. If you enable automatic selection of the medium type, the device uses the current medium if only one medium is available. If both media are available, the device uses the preferred medium as configured. By default, the preferred medium is copper. You can run the **medium-type auto-select prefer fiber** command to configure fiber as the preferred media. In automatic medium selection mode, the interface adopts the default settings of attributes, such as the speed, duplex mode, and flow control mode.

Configuring the Speed of an Interface

- Optional.
- Port flapping may occur if the configured speed of a port changes.
- This command is applicable to an Ethernet physical port or AP port.

Command	**speed** [**10** | **100** | **1000** | **auto**]
Parameter Description	**10**: Indicates that the speed of the interface is 10 Mbps. **100**: Indicates that the speed of the interface is 100 Mbps. **1000**: Indicates that the speed of the interface is 1000 Mbps. **auto**: Indicates that the speed of the interface automatically adapts to the actual condition.
Defaults	By default, the speed of an interface is auto.
Command Mode	Interface configuration mode
Usage Guide	If an interface is an AP member port, the speed of this interface is determined by the speed of the AP port. When the interface exits the AP port, it uses its own speed configuration. You can run **show interfaces** to display the speed configurations. The speed options available to an interface vary with the type of the interface. For example, you cannot set the speed of an SFP interface to 10 Mbps.

Configuring the Duplex Mode of an Interface

- Optional.
- Port flapping may occur if the configured duplex mode of a port changes.
- This command is applicable to an Ethernet physical port or AP port.

Command	**duplex** { **auto** | **full** | **half** }
Parameter Description	**auto**: Indicates automatic switching between full duplex and half duplex. **full**: Indicates full duplex. **half**: Indicates half duplex.
Defaults	By default, the duplex mode of an interface is auto.
Command Mode	Interface configuration mode
Usage Guide	The duplex mode of an interface is related to the interface type. You can run **show interfaces** to display the configurations of the duplex mode.

Configuring the MTU of an Interface

- Optional.
- You can configure the MTU of a port to limit the length of a frame that can be received or sent over this port.
- This command is applicable to an Ethernet physical port or SVI.

Command	**mtu** *num*
Parameter Description	*num*: *64–9216*

Defaults	By default, the MTU of an interface is 1500 bytes.
Command Mode	Interface configuration mode
Usage Guide	This command is used to configure the interface MTU, that is, the maximum length of a data frame at the link layer. Currently, you can configure MTU for only a physical port or an AP port that contains one or more member ports.

Configuring the Bandwidth of an Interface

- Optional.
- Generally, the bandwidth of an interface is the same as the speed of the interface.

Command	**bandwidth** *kilobits*
Parameter Description	*kilobits*: The value ranges from 1 to 2,147,483,647. The unit is kilo bits.
Defaults	Generally, the bandwidth of an interface matches the type of the interface. For example, the default bandwidth of a gigabit Ethernet physical port is 1,000,000, and that of a 10G Ethernet physical port is 10,000,000.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring the Carrier Delay of an Interface

- Optional.
- If the configured carrier delay is long, it takes a long time to change the protocol status when the physical status of an interface changes. If the carrier delay is set to 0, the protocol status changes immediately after the physical status of an interface changes.

Command	**carrier-delay** *seconds*
Parameter Description	*seconds*: The value ranges from 0 to 60. The unit is second.
Defaults	By default, the carrier delay of an interface is 2s.
Command Mode	Interface configuration mode
Usage Guide	

Configuring the Load Interval of an Interface

- Optional.
- The configured load interval affects computation of the average packet rate on an interface. If the configured load interval is short, the average packet rate can accurately reflect the changes of the real-time traffic.

Command	**load-interval** *seconds*
Parameter De	*seconds*: The value ranges from 5 to 600. The unit is second.

scription	
Defaults	By default, the load interval of an interface is 10s.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring Port Errdisable Recovery

- Optional.
- By default, a port will be disabled and will not be recovered after a violation occurs. After port errdisable recovery is configured, a port in errdisable state will be recovered and enabled.

Command	**errdisable recovery [interval** *time***]**
Parameter Description	*time*: Indicates the automatic recovery time. The value ranges from 30 to 86,400. The unit is second.
Defaults	By default, port errdisable recovery is disabled.
Command Mode	Global configuration mode
Usage Guide	By default, a port in errdisable state is not recovered. You can recover the port manually or run this command to automatically recover the port.

Verification

- Run the **show interfaces** command to display the attribute configurations of interfaces.

Command	**show interfaces** [*interface-type interface-number*] [**description | switchport | trunk**]
Parameter Description	*interface-type interface-number*: Indicates the type and number of the interface. **description**: Indicates the interface description, including the link status. **switchport**: Indicates the L2 interface information. This parameter is effective only for a L2 interface. **trunk**: Indicates the Trunk port information. This parameter is effective for a physical port or an AP port.
Command Mode	Privileged EXEC mode
Usage Guide	Use this command without any parameter to display the basic interface information.
	SwitchA#show interfaces GigabitEthernet 0/1 Index(dec):1 (hex):1 GigabitEthernet 0/1 is DOWN, line protocol is DOWN Hardware is Broadcom 5464 GigabitEthernet, address is 00d0.f865.de9b (bia 00d0.f865.de9b) Interface address is: no ip address Interface IPv6 address is: No IPv6 address MTU 1500 bytes, BW 1000000 Kbit

Configuration Example

Configuring Interface Attributes

Scenario **Figure 1-1**	Configuration Steps	● On Switch A, configure GigabitEthernet 0/1 as an access mode, and the default VLAN ID is 1. Configure SVI 1, assign an IP address to SVI 1, and set up a route to Switch D. ● On Switch B, configure GigabitEthernet 0/1 and GigabitEthernet 0/2 as Trunk ports, and the default VLAN ID is 1. Configure SVI 1, and assign an IP address to SVI 1. Configure GigabitEthernet 0/3 as a routed port, and assign an IP address from another network segment to this port. ● On Switch C, configure GigabitEthernet 0/1 as an Access port, and the default VLAN ID is 1. Configure SVI 1, and assign an IP address to SVI 1. ● On Switch D, configure GigabitEthernet 0/1 as a routed port, assign an IP address to this port, and set up a route to Switch A.
A	A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# switchport mode access A(config-if-GigabitEthernet 0/1)# switchport access vlan 1 A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip address 192.168.1.1 255.255.255.0 A(config-if-VLAN 1)# exit A(config)# ip route 192.168.2.0 255.255.255.0 VLAN 1 192.168.1.2

1.5 Monitoring

Clearing

⚠ Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the counters of a specified interface.	**clear counters** [*interface-type interface-number*]

Resets the interface hardware.	**clear interface** *interface-type interface-number*

Displaying

Displaying Interface Configurations and Status

Description	Command
Displays all the status and configuration information of a specified interface.	**show interfaces** [*interface-type interface-number*]
Displays the interface status.	**show interfaces** [*interface-type interface-number*] **status**
Displays the interface errdisable status.	**show interfaces** [*interface-type interface-number*] **status err-disable**
Displays the link status change time and count of a specified port.	**show interfaces** [*interface-type interface-number*] **link-state-change statistics**
Displays the administrative and operational states of switch ports (non-routed ports).	**show interfaces** [*interface-type interface-number*] **switchport**
Displays the description and status of a specified interface.	**show interfaces** [*interface-type interface-number*] **description**
Displays the counters of a specified port, among which the displayed speed may have an error of ±0.5%.	**show interfaces** [*interface-type interface-number*] **counters**
Displays the number of packets increased in a load interval.	**show interfaces** [*interface-type interface-number*] **counters increment**
Displays statistics about error packets.	**show interfaces** [*interface-type interface-number*] **counters error**
Displays the packet sending/receiving rate of an interface.	**show interfaces** [*interface-type interface-number*] **counters rate**
Displays a summary of interface information.	**show interfaces** [*interface-type interface-number*] **counters summary**
Displays the bandwidth usage of an interface.	**show interfaces** [*interface-type interface-number*] **usage**

2 Configuring MAC Address

2.1 Overview

A MAC address table contains the MAC addresses, interface numbers and VLAN IDs of the devices connected to the local device.

When a device forwards a packet, it finds an output port from its MAC address table according to the destination MAC address and the VLAN ID of the packet.

After that, the packet is unicast, multicast or broadcast.

This document covers dynamic MAC addresses, static MAC addresses and filtered MAC addresses. For the management of multicast MAC addresses, please see *Configuring IGMP Snooping Configuration*.

Protocols and Standards

- IEEE 802.3: Carrier sense multiple access with collision detection (CSMA/CD) access method and physical layer specifications
- IEEE 802.1Q: Virtual Bridged Local Area Networks

2.2 Applications

Application	Description
MAC Address Learning	Forward unicast packets through MAC addresses learning.
MAC Address Change Notification	Monitor change of the devices connected to a network device through MAC address change notification.

2.2.1 MAC Address Learning

Scenario

Usually a device maintains a MAC address table by learning MAC addresses dynamically. The operating principle is described as follows:

As shown in the following figure, the MAC address table of the switch is empty. When User A communicates with User B, it sends a packet to the port GigabitEthernet 0/2 of the switch, and the switch learns the MAC address of User A and stores it in the table.
As the table does not contain the MAC address of User B, the switch broadcasts the packet to the ports of all connected devices except User A, including User B and User C.

Figure 2-1 Step 1 of MAC Address Learning

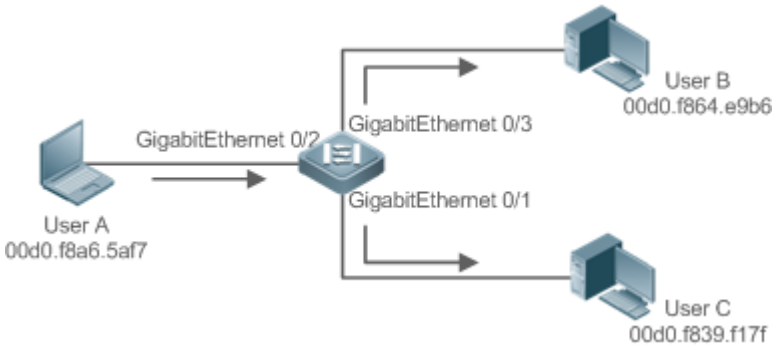

Figure 2-2 MAC Address Table 1

Status	VLAN	MAC address	Interface
Dynamic	1	00d0.f8a6.5af7	GigabitEthernet 0/2

When User B receives the packet, it sends a reply packet to User A through port GigabitEthernet 0/3 on the switch. As the MAC address of User A is already in the MAC address table, the switch send the reply unicast packet to port GigabitEthernet 0/2 port and learns the MAC address of User B. User C does not receive the reply packet from User B to User A.

Figure 2-3 Step 2 of MAC Address Learning

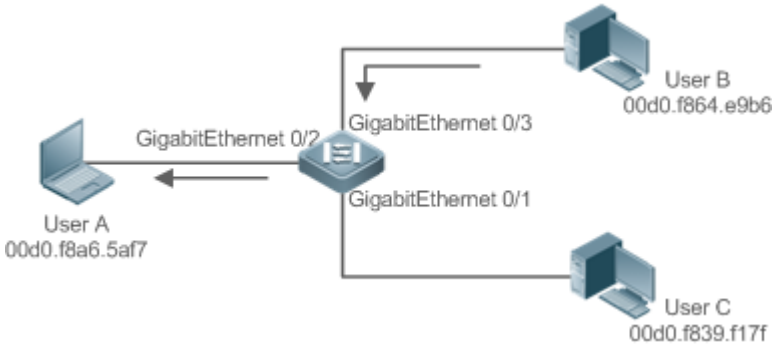

Figure 2-4 MAC Address Table 2

Status	VLAN	MAC address	Interface
Dynamic	1	00d0.f8a6.5af7	GigabitEthernet 0/2
Dynamic	1	00d0.f8a4.e9b6	GigabitEthernet 0/3

Through the interaction between User A and User B, the switch learns the MAC addresses of User A and User B. After that, packets between User A and User B will be exchanged via unicast without being received by User C.

Deployment

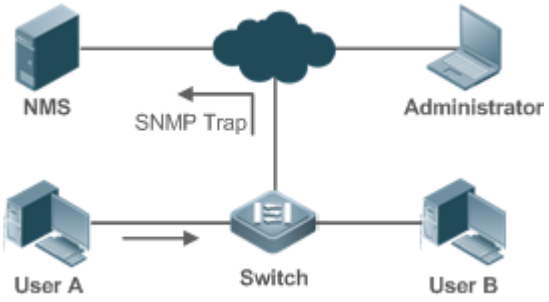
- With MAC address learning, a layer-2 switch forwards packets through unicast, reducing broadcast packets and network load.

2.2.2 MAC Address Change Notification

MAC address change notification provides a mechanism for the network management system (NMS) to monitor the change of devices connected to a network device.

Scenario

Figure 2-5 MAC Address Change Notification



After MAC address change notification is enabled on a device, the device generates a notification message when the device learns a new MAC address or finishes aging a learned MAC address, and sends the message in an SNMP Trap message to a specified NMS.

A notification of adding a MAC address indicates that a new user accesses the network, and that of deleting a MAC address indicates that a user sends no packets within an aging time and usually the user exits the network.

When a network device is connected to a number of devices, a lot of MAC address changes may occur in a short time, resulting in an increase in traffic. To reduce traffic, you may configure an interval for sending MAC address change notifications. When the interval expires, all notifications generated during the interval are encapsulated into a message.

±When a notification is generated, it is stored in the table of historical MAC address change notifications. The administrator may know recent MAC address changes by checking the table of notification history even without NMS.

A MAC address change notification is generated only for a dynamic MAC address.

Deployment

- Enable MAC address change notification on a layer-2 switch to monitor the change of devices connected to a network device.

2.3 Features

Basic Concepts

Dynamic MAC Address

A dynamic MAC address is a MAC address entry generated through the process of MAC address learning by a device.

Address Aging

A device only learns a limited number of MAC addresses, and inactive entries are deleted through address aging.

A device starts aging a MAC address when it learns it. If the device receives no packet containing the source MAC address, it will delete the MAC address from the MAC address table when the time expires.

Forwarding via Unicast

If a device finds in its MAC address table an entry containing the MAC address and the VLAN ID of a packet and the output port is unique, it will send the packet through the port directly.

Forwarding via Broadcast

If a device receives a packet containing the destination address ffff.ffff.ffff or an unidentified destination address, it will send the packet through all the ports in the VLAN where the packet is from, except the input port.

2.4 Configuration

Configuration	Description and Command	
Configuring Dynamic MAC Address	(Optional) It is used to enable MAC address learning.	
	mac-address-learning	Configures MAC address learning globally or on an interface.
	mac-address-table aging-time	Configures an aging time for a dynamic MAC address.
Configuring a Static MAC Address	(Optional) It is used to bind the MAC address of a device with a port of a switch.	
	mac-address-table static	Configures a static MAC address.
Configuring a MAC Address for Packet Filtering	(Optional) It is used to filter packets.	
	mac-address-table filtering	Configures a MAC address for packet filtering.
Configuring MAC Address Change Notification	(Optional) It is used to monitor change of devices connected to a network device.	
	mac-address-table notification	Configures MAC address change notification globally.
	snmp trap mac-notification	Configures MAC address change notification on an interface.

2.4.1 Configuring Dynamic MAC Address

Configuration Effect

Learn MAC addresses dynamically and forward packets via unicast.

Configuration Steps

Configuring MAC Address Learning on Interface

- Optional.
- You can perform this configuration to disable MAC address learning on an interface.

Command	**mac-address-learning**
Parameter Description	**N/A**
Defaults	MAC address learning is enabled by default.
Command Mode	Interface configuration mode
Usage Guide	Perform this configuration on a layer-2 interface, for example, a switch port or an AP port.

By default, MAC address learning is enabled. If DOT1X, IP SOURCE GUARD, or a port security function is configured on a port, MAC address learning cannot be enabled. Access control cannot be enabled on a port with MAC address learning disabled.

Configuring an Aging Time for a Dynamic MAC Address

- Optional.
- Configure an aging time for dynamic MAC addresses.

Command	**mac-address-table aging-time** *value*
Parameter Description	*value*: Indicates the aging time. The value is either 0 or in the range from 10 to 1000,000.
Defaults	The default is 300s.
Command Mode	Global configuration mode
Usage Guide	If the value is set to 0, MAC address aging is disabled and learned MAC addresses will not be aged.

The actual aging time may be different from the configured value, but it is not more than two times of the configured value.

Verification

- Check whether a device learns dynamic MAC addresses.
- Run the **show mac-address-table dynamic** command to display dynamic MAC addresses.
- Run the **show mac-address-table aging-time** command to display the aging time for dynamic MAC addresses.

Command	**show mac-address-table dynamic** [**address** *mac-address*] [**interface** *interface-id*] [**vlan** *vlan-id*]
Parameter Description	**address** *mac-address*: Displays the information of a specific dynamic MAC address. **interface** *interface-id*: Specifies a physical interface or an AP port.

	vlan *vlan-id*: Displays the dynamic MAC addresses in a specific VLAN.
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A
	Ruijie# show mac-address-table dynamic Vlan MAC Address Type Interface ---- ---------- ------ ---------- **1 0000.0000.0001 DYNAMIC GigabitEthernet 1/1** **1 0001.960c.a740 DYNAMIC GigabitEthernet 1/1** **1 0007.95c7.dff9 DYNAMIC GigabitEthernet 1/1** **1 0007.95cf.eee0 DYNAMIC GigabitEthernet 1/1** **1 0007.95cf.f41f DYNAMIC GigabitEthernet 1/1** **1 0009.b715.d400 DYNAMIC GigabitEthernet 1/1** **1 0050.bade.63c4 DYNAMIC GigabitEthernet 1/1**

Field	Description
Vlan	Indicates the VLAN where the MAC address resides.
MAC Address	Indicates a MAC Address.
Type	Indicates a MAC address type.
Interface	Indicates the interface where the MAC address resides.

Command	**show mac-address-table aging-time**
Parameter Description	N/A
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A
	Ruijie# show mac-address-table aging-time **Aging time: 300**

Configuration Example

Configuring Dynamic MAC Address

Scenario **Figure 2-6**	Configuration Steps	● Enable MAC address learning on an interface. ● Configure the aging time for dynamic MAC addresses to 180s. ● Delete all dynamic MAC addresses in VLAN 1 on port GigabitEthernet 0/1.
	Ruijie# configure terminal Ruijie(config-if-GigabitEthernet 0/1)# mac-address-learning Ruijie(config-if-GigabitEthernet 0/1)# exit Ruijie(config)# mac aging-time 180 Ruijie# clear mac-address-table dynamic interface GigabitEthernet 0/1 vlan 1
Verification	● Check MAC address learning on an interface. ● Display the aging time for dynamic MAC addresses. ● Display all dynamic MAC addresses in VLAN 1 on port GigabitEthernet 0/1.
	Ruijie# show mac-address-learning **GigabitEthernet 0/1 learning ability: enable** Ruijie# show mac aging-time Aging time : **180 seconds** Ruijie# show mac-address-table dynamic interface GigabitEthernet 0/1 vlan 1 Vlan MAC Address Type Interface ---------- -------------------- -------- -------------------- **1 00d0.f800.1001 STATIC GigabitEthernet 1/1**

Common Errors

Configure MAC address learning on an interface before configuring the interface as a layer-2 interface, for example, a switch port or an AP port.

2.4.2 Configuring a Static MAC Address

Configuration Effect

- Bind the MAC address of a network device with a port of a switch.

Configuration Steps

Configuring a Static MAC address

- Optional.
- Bind the MAC address of a network device with a port of a switch.

Command	**mac-address-table static** *mac-address* **vlan** *vlan-id* **interface** *interface-id*
Parameter Description	**address** *mac-address*: Specifies a MAC address. **vlan** *vlan-id*: Specifies a VLAN where the MAC address resides. **interface** *interface-id*: Specifies a physical interface or an AP port.
Defaults	By default, no static MAC address is configured.
Command Mode	Global configuration mode
Usage Guide	When the switch receives a packet containing the specified MAC address on the specified VLAN, the packet is forwarded to the bound interface.

Verification

- Run the **show mac-address-table static** command to check whether the configuration takes effect.

Command	**show mac-address-table static** [**address** *mac-address*] [**interface** *interface-id*] [**vlan** *vlan-id*]
Parameter Description	**address** *mac-address*: Specifies a MAC address. **interface** *interface-id*: Specifies a physical interface or an AP port. **vlan** *vlan-id*: Specifies a VLAN where the MAC address resides.
Command Mode	Privileged EXEC mode/Global configuration mode /Interface configuration mode
Usage Guide	N/A
	Ruijie# show mac-address-table static Vlan MAC Address Type Interface ----- ----------- -------- ------------------ **1 00d0.f800.1001 STATIC GigabitEthernet 1/1** **1 00d0.f800.1002 STATIC GigabitEthernet 1/1** **1 00d0.f800.1003 STATIC GigabitEthernet 1/1**

Configuration Example

Configuring a Static MAC address

In the above example, the relationship of MAC addresses, VLAN and interfaces is shown in the following table.

Role	MAC Address	VLAN ID	Interface ID
Web Server	00d0.3232.0001	VLAN2	Gi0/10
Database Server	00d0.3232.0002	VLAN2	Gi0/11

Administrator	00d0.3232.1000	VLAN2	Gi0/12
Scenario **Figure 2-7**			
Configuration Steps	● Specify destination MAC addresses (*mac-address*). ● Specify the VLAN (*vlan-id*) where the MAC addresses reside. ● Specify interface IDs (*interface-id*).		
A	A# configure terminal A(config)# mac-address-table static 00d0.f800.3232.0001 vlan 2 interface gigabitEthernet 0/10 A(config)# mac-address-table static 00d0.f800.3232.0002 vlan 2 interface gigabitEthernet 0/11 A(config)# mac-address-table static 00d0.f800.3232.1000 vlan 2 interface gigabitEthernet 0/12		
Verification	Display the static MAC address configuration on a switch.		
A	A# show mac-address-table static Vlan MAC Address Type Interface ---------- ---------- -------- ---------- **2 00d0.f800.3232.0001 STATIC GigabitEthernet 0/10** **2 00d0.f800.3232.0002 STATIC GigabitEthernet 0/11** **2 00d0.f800.3232.1000 STATIC GigabitEthernet 0/12**		

Common Errors

- Configure a static MAC address before configuring the specific port as a layer-2 interface, for example, a switch port or an AP port.

2.4.3 Configuring a MAC Address for Packet Filtering

Configuration Effect

- If a device receives packets containing a source MAC address or destination MAC address specified as the filtered MAC address, the packets are discarded.

Configuration Steps

Configuring a MAC Address for Packet Filtering

- Optional.
- Perform this configuration to filter packets.

Command	**mac-address-table filtering** *mac-address* **vlan** *vlan-id*
Parameter Description	**address** *mac-address*: Specifies a MAC address. **vlan** *vlan-id*: Specifies a VLAN where the MAC address resides.
Defaults	By default, no filtered MAC address is configured.
Command Mode	Global configuration mode
Usage Guide	If a device receives packets containing a source MAC address or destination MAC address specified as the filtered MAC address, the packets are discarded.

Verification

- Run the **show mac-address-table filter** command to display the filtered MAC address.

Command	**show mac-address-table filter** [**address** *mac-address*] [**vlan** *vlan-id*]
Parameter Description	**address** *mac-address*: Specifies a MAC address. **vlan** *vlan-id*: Specifies a VLAN where the MAC address resides.
Command Mode	Privileged EXEC mode/Global configuration mode /Interface configuration mode
Usage Guide	N/A
	Ruijie# show mac-address-table filtering Vlan MAC Address Type Interface ------ -------------------- -------- ----------- **1 0000.2222.2222 FILTER**

Configuration Example

Configuring a MAC Address for Packet Filtering

Configuration Steps	● Specify a destination MAC address (*mac-address*) for filtering. ● Specify a VLAN where the MAC addresses resides.
	Ruijie# configure terminal Ruijie(config)# mac-address-table static 00d0.f800.3232.0001 vlan 1

Verification	Display the filtered MAC address configuration.
	Ruijie# show mac-address-table filter Vlan MAC Address Type Interface ---------- -------------------- -------- -------------------- **1 00d0.f800.3232.0001 FILTER**

2.4.4 Configuring MAC Address Change Notification

Configuration Effect

- Monitor change of devices connected to a network device.

Configuration Steps

Configuring NMS

- Optional.
- Perform this configuration to enable an NMS to receive MAC address change notifications.

Command	**snmp-server host** *host-addr* **traps** [**version** { **1** | **2c** | **3** [**auth** | **noauth** | **priv**] }] *community-string*
Parameter Description	**host** *host-addr*: Specifies the IP address of a receiver. **version** { **1** | **2c** | **3** [**auth** | **noauth** | **priv**] }: Specifies the version of SNMP TRAP messages. You can also specify authentication and a security level for packets of Version 3. *community-string*: Indicates an authentication name.
Defaults	By default, the function is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling SNMP Trap

- Optional.
- Perform this configuration to send SNMP Trap messages.

Command	**snmp-server enable traps**
Parameter Description	N/A
Defaults	By default, the function is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring Global MAC Address Change Notification

- Optional.
- If MAC address change notification is disabled globally, it is disabled on all interfaces.

Command	**mac-address-table notification**
Parameter Description	N/A
Defaults	By default, MAC address change notification is disabled globally.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring MAC Address Change Notification On Interface

- Optional.
- Perform this configuration to enable MAC address change notification on an interface.

Command	**snmp trap mac-notification** { **added** | **removed** }
Parameter Description	**added**: Generates a notification when an MAC address is added. **removed**: Generates a notification when an MAC address is deleted.
Defaults	By default, MAC address change notification is disabled on an interface.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring Interval for Generating MAC Address Change Notifications and Volume of Notification History

- Optional.
- Perform this configuration to modify the interval for generating MAC address change notifications and the volume of notification history.

Command	**mac-address-table notification** { **interval** *value* | **history-size** *value* }
Parameter Description	**interval** *value*: (Optional) Indicates the interval for generating MAC address change notifications. The value ranges from 1 to 3600 seconds,. **history-size** *value*: Indicates the maximum number of entries in the table of notification history. The value ranges from 1 to 200.
Defaults	The default interval is 1 second. The default maximum amount of notifications is 50.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

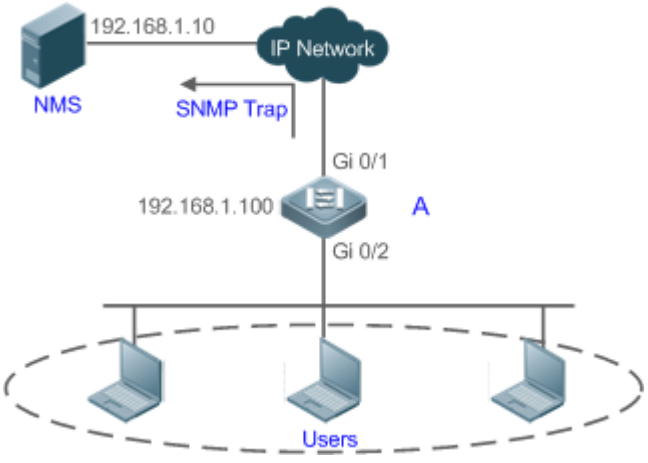
- Run the **show mac-address-table notification** command to check whether the NMS receives MAC address change notifications.

Command	**show mac-address-table notification [interface [*interface-id*] | history]**
Parameter Description	**Interface**:Displays the configuration of MAC address change notification on all interfaces. ***interface-id***: Displays the configuration of MAC address change notification on a specified interface. **history**: Displays the history of MAC address change notifications.
Command Mode	Privileged EXEC mode/Global configuration mode /Interface configuration mode
Usage Guide	N/A
Usage Guide	Display the configuration of global MAC address change notification. Ruijie#show mac-address-table notification MAC Notification Feature : **Enabled** Interval(Sec): **300** Maximum History Size : **50** Current History Size : **0**

Field	Description
Interval(Sec)	Indicates the interval for generating MAC address change notifications.
Maximum History Size	Indicates the maximum number of entries in the table of notification history.
Current History Size	Indicates the current notification entry number.

Configuration Example

Scenario
Figure 2-8



The figure shows an intranet of an enterprise. Users are connected to A via port Gi0/2.

The Perform the configuration to achieve the following effects:

	● When port Gi0/2 learns a new MAC address or finishes aging a learned MAC address, a MAC address change notification is generated. ● Meanwhile, A sends the MAC address change notification in an SNMP Trap message to a specified NMS. ● In a scenario where A is connected to a number of Users, the configuration can prevent MAC address change notification burst in a short time so as to reduce the network flow.
Configuration Steps	● Enable global MAC address change notification on A, and configure MAC address change notification on port Gi0/2. ● Configure the IP address of the NMS host, and enable A with SNMP Trap. A communicates with the NMS via routing. ● Configure the interval for sending MAC address change notifications to 300 seconds (1 second by default).
A	Ruijie# configure terminal Ruijie(config)# mac-address-table notification Ruijie(config)# interface gigabitEthernet 0/2 Ruijie(config-if-GigabitEthernet 0/2)# snmp trap mac-notification added Ruijie(config-if-GigabitEthernet 0/2)# snmp trap mac-notification removed Ruijie(config-if-GigabitEthernet 0/2)# exit Ruijie(config)# snmp-server host 192.168.1.10 traps version 2c comefrom2 Ruijie(config)# snmp-server enable traps Ruijie(config)# mac-address-table notification interval 300
Verification	● Check t whether MAC address change notification is enabled globally . ● Check whether MAC address change notification is enabled on the interface. ● Display the MAC addresses of interfaces, and run the **clear mac-address-table dynamic** command to simulate aging dynamic MAC addresses. ● Check whether global MAC address change notification is enabled globally. ● Display the history of MAC address change notifications.
A	Ruijie# show mac-address-table notification MAC Notification Feature : **Enabled** Interval(Sec): **300** Maximum History Size : **50** Current History Size : **0** Ruijie# show mac-address-table notification interface GigabitEthernet 0/2 Interface MAC Added Trap MAC Removed Trap

	---------- ---------- ---------- GigabitEthernet 0/2 Enabled Enabled Ruijie# show mac-address-table interface GigabitEthernet 0/2 Vlan MAC Address Type Interface ---------- -------------------- -------- -------------------- 1 00d0.3232.0001 DYNAMIC GigabitEthernet 0/2 Ruijie# show mac-address-table notification MAC Notification Feature : Enabled Interval(Sec): 300 Maximum History Size : 50 Current History Size : 1 Ruijie# show mac-address-table notification history History Index : 0 Entry Timestamp: 221683 MAC Changed Message : Operation:DEL Vlan:1 MAC Addr: 00d0.3232.0003 GigabitEthernet 0/2

Common Errors

None

2.5 Monitoring

Clearing

Running the clear commands may lose vital information and interrupt services.

Description	Command
Clears dynamic MAC addresses.	**clear mac-address-table dynamic** [**address** *mac-address*] [**interface** *interface-id*] [**vlan** *vlan-id*]

Displaying

Description	Command
Displays the MAC address table.	**show mac-address-table** { **dynamic** | **static** | **filter** } [**address** *mac-address* **]** [**interface** *interface-id*] [**vlan** *vlan-id*]
Displays the aging time for dynamic MAC addresses.	**show mac-address-table aging-time**

Displays the configuration and history of MAC address change notifications.	**show mac-address-table notification [interface [*interface-id*] | history]**

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs MAC address operation.	**debug bridge mac**

3 Configuring Aggregated Port

3.1 Overview

An aggregated port (AP) is used to bundle multiple physical links into one logical link to increase the link bandwidth and improve connection reliability.

An AP port supports load balancing, namely, distributes load evenly among member links. Besides, an AP port realizes link backup. When a member link of the AP port is disconnected, the load carried by the link is automatically allocated to other functional member links. A member link does not forward broadcast or multicast packets to other member links.

For example, the link between two devices supports a maximum bandwidth of 1,000 Mbps. When the service traffic carried by the link exceeds 1,000 Mbps, the traffic in excess will be discarded. Port aggregation can be used to solve the problem. For example, you can connect the two devices with network cables and combine multiple links to form a logical link capable of multiples of 1,000 Mbps.

For example, there are two devices connected by a network cable. When the link between the two ports of the devices is disconnected, the services carried by the link will be interrupted. After the connected ports are aggregated, the services will not be affected as long as one link remains connected.

Protocols and Standards

- IEEE 802.3ad

3.2 Applications

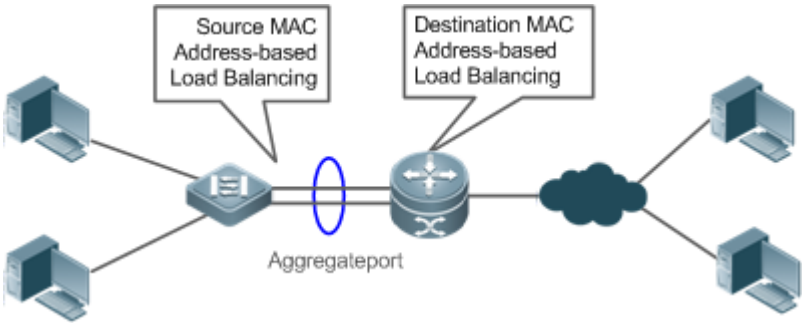
Applications	Description
AP Link Aggregation and Load Balancing	A large number of packets are transmitted between an aggregation device and a core device, which requires a greater bandwidth. To meet this requirement, you can bundle the physical links between the devices into one logical link to increase the link bandwidth, and configure a proper load balancing algorithm to distribute the work load evenly to each physical link, thus improving bandwidth utilization.

3.2.1 AP Link Aggregation and Load Balancing

Scenario

In Figure 1-1, the switch communicates with the router through an AP port. All the devices on the intranet (such as the two PCs on the left) use the router as a gateway. All the devices on the extranet (such as the two PCs on the right) send packets to the internet devices through the router, with the gateway's MAC address as its source MAC address. To distribute the load between the router and other hosts to other links, configure destination MAC address-based load balancing. On the switch, configure source MAC address-based load balancing.

Figure 3-1 AP Link Aggregation and Load Balancing



Deployment

- Configure the directly connected ports between the switch and router as a static AP port or a Link Aggregation Control Protocol (LACP) AP port.
- On the switch, configure a source MAC address-based load balancing algorithm.
- On the router, configure a destination MAC address-based load balancing algorithm.

3.3 Features

Basic Concepts

Static AP

The static AP mode is an aggregation mode in which physical ports are directly added to an AP aggregation group through manual configuration to allow the physical ports to forward packets when the ports are proper in link state and protocol state.

An AP port in static AP mode is called a static AP, and its member ports are called static AP member ports.

LACP

LACP is a protocol about dynamic link aggregation. It exchanges information with the connected device through LACP data units (LACPDUs).

An AP port in LACP mode is called an LACP AP port, and its member ports are called LACP AP member ports.

AP Member Port Mode

There are three aggregation modes available, namely, active, passive, and static.

AP member ports in active mode initiate LACP negotiation. AP member ports in passive mode only respond to received LACPDUs. AP member ports in static mode do not send LACPDUs for negotiation. The following table lists the requirements for peer port mode.

Port Mode	Peer Port Mode
Active mode	Active or passive mode
Passive mode	Active mode
Static Mode	Static Mode

AP Member Port State

There are two kinds of AP member port state available:

- When a member port is Down, the port cannot forward packets. The Down state is displayed.
- When a member port is Up and the link protocol is ready, the port can forward packets. The Up state is displayed.

There are three kinds of LACP member port state:

- When the link of a port is Down, the port cannot forward packets. The Down state is displayed.
- When the link of a port is Up and the port is added to an aggregation group, the bndl state is displayed.
- When the link of a port is Up but the port is suspended because the peer end is not enabled with LACP or the attributes of the ports are inconsistent with those of the master port, the susp state is displayed. (The port in susp state does not forward packets.)

Only full-duplex ports are capable of LACP aggregation.

LACP aggregation can be implemented only when the rates, flow control approaches, medium types, and Layer-2/3 attributes of member ports are consistent.

If you modify the preceding attributes of a member port in the aggregation group, LACP aggregation will fail.

The ports which are prohibited from joining or exiting an AP port cannot be added to or removed from a static AP port or an LACP AP port.

LACP System ID

One device can be configured with only one LACP aggregation system. The system is identified by a system ID and each system has a priority, which is a configurable value. The system ID consists of the LACP system priority and MAC address of the device. A lower system priority indicates a higher priority of the system ID. If the system priorities are the same, a smaller MAC address of the device indicates a higher priority of the system ID. The system with an ID of a higher priority determines the port state. The port state of a system with an ID of a lower priority keeps consistent with that of a higher priority.

LACP Port ID

Each port has an independent LACP port priority, which is a configurable value. The port ID consists of the LACP port priority and port number. A smaller port priority indicates a higher priority of the port ID. If the port priorities are the same, a smaller port number indicates a higher priority of the port ID.

LACP Master Port

When dynamic member ports are Up, LACP selects one of those ports to be the master port based on the rates and duplex modes, ID priorities of the ports in the aggregation group, and the bundling state of the member ports in the Up state. Only the ports that have the same attributes as the master port are in Bundle state and participate in data forwarding. When the attributes of ports are changed, LACP reselects a master port. When the new master port is not in Bundle state, LACP disaggregates the member ports and performs aggregation again.

LACP Independent Ports

In normal cases, LACP independent ports are used for interworking between access switches and servers with two NICs. If the OS is not pre-installed when a server with two NICs starts, the OS needs to be installed via the remote PXE OS installation device. Before the OS is installed, the server with two NICs cannot perform LACP negotiation with the access device, and only one NIC can work. In this case, the port on the access device must be able to change to a common Ethernet physical port automatically to ensure normal communication between the server and the remote PXE OS installation device. After the OS is installed and both NICs can run the LACP, the port on the access device must be able to enable the LACP again for negotiation.

LACP independent ports can work only at layer 2. After an LACP independent port is enabled, if the LACP independent port does not receive LACP packets, it automatically changes to a common Ethernet port, which automatically copies the rate, duplex mode, flow control, and VLAN configuration from the AP port to ensure port forwarding capabilities.

An LACP independent port automatically changes to a common Ethernet port only if it does not receive LACP packets within 90s. After the port receives LACP packets, it changes to an LACP member port again.

Overview

Overview	Description
Link Aggregation	Aggregates physical links statically or dynamically to realize bandwidth extension and link backup.
Load Balancing	Balances the load within an aggregation group flexibly by using different load balancing methods.

3.3.1 Link Aggregation

Working Principle

There are two kinds of AP link aggregation. One is static AP, and the other is dynamic aggregation through LACP.

- Static AP

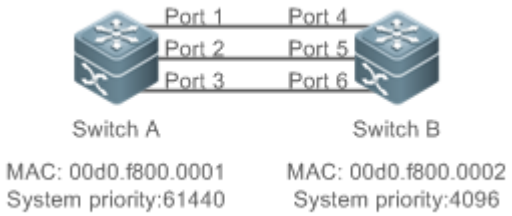
The static AP configuration is simple. Run a command to add the specified physical port to the AP port. After joining the aggregation group, a member port can receive and transmit data and participate in load balancing within the group.

- Dynamic AP (LACP)

An LACP-enabled port sends LACPDUs to advertise its system priority, system MAC address, port priority, port number, and operation key. When receiving the LACPDU from the peer end, the device compares the system priorities of both ends based on the system ID in the packet. The end with a higher system ID priority sets the ports in the aggregation group to Bundle state based on the port ID priorities in a descending order, and sends an updated LACPDU. When receiving the LACPDU, the peer end sets corresponding ports to Bundle state so that both ends maintain consistency when a port exits or joins the aggregation group. The physical link can forward packets only after the ports at both ends are bundled dynamically.

After link aggregation, the LACP member ports periodically exchange LACPDUs. When a port does not receive an LACPDU in the specified time, a timeout occurs and the links are unbundled. In this case, the member ports cannot forward packets. There are two timeout modes: long timeout and short timeout. In long timeout mode, a port sends a packet every 30s. If it does not receive a packet from the peer end in 90s, a timeout occurs. In short timeout mode, a port sends a packet every 1s. If it does not receive a packet from the peer end in 3s, a timeout occurs.

Figure 3-1 LACP Negotiation



In Figure 1-2, Switch A is connected to Switch B through three ports. Set the system priorities of Switch A and Switch B to 61440 and 4096 respectively. Enable LACP on the Ports 1–6, set the aggregation mode to the active mode, and set the port priority to the default value 32768.

When receiving an LACPDU from Switch A, Switch B finds that it has a higher system ID priority than Switch A (the system priority of Switch B is higher than that of Switch A). Switch B sets Port 4, Port 5, and Port 6 to Bundle state based on the order of port ID priorities (or in an ascending order of port numbers if the port priorities are the same). When receiving an updated LACPDU from Switch B, Switch A finds that Switch B has a higher system ID priority and has set Port 4, Port 5, and Port 6 to Bundle state. Then Switch A also sets Port 1, Port 2, and Port 3 to Bundle state.

3.3.2 Load Balancing

Working Principle

AP ports segregate packet flows by using load balancing algorithms based on packet features, such as the source and destination MAC addresses, source and destination IP addresses, and Layer-4 source and destination port numbers. The packet flow with the consistent feature is transmitted by one member link, and different packet flows are evenly distributed to member links. For example, in source MAC address-based load balancing, packets are distributed to the member links based on the source MAC addresses of the packets. Packets with different source MAC addresses are evenly distributed to member links. Packets with the identical source MAC address are forwarded by one member link.

Currently, there are several AP load balancing modes as follows:

- Source MAC address or destination MAC address
- Source MAC address + destination MAC address
- Source IP address or destination IP address
- Source IP address + destination IP address
- Layer-4 source port number or Layer-4 destination port number
- Layer-4 source port number + Layer-4 destination port number
- Source IP address + Layer-4 source port number
- Source IP address + Layer-4 destination port number
- Destination IP address + Layer-4 source port number
- Destination IP address + Layer-4 destination port number
- Source IP address + Layer-4 source port number + Layer-4 destination port number

- Destination IP address + Layer-4 source port number + Layer-4 destination port number
- Source IP address + destination IP address + Layer-4 source port number
- Source IP address + destination IP address + Layer-4 destination port number
- Source IP address + destination IP address + Layer-4 source port number + Layer-4 destination port number

Load balancing based on IP addresses or port numbers is applicable only to Layer-3 packets. When a device enabled with this load balancing method receives Layer-2 packets, it automatically switches to the default load balancing method.

All the load balancing methods use a load algorithm (hash algorithm) to calculate the member links based on the input parameters of the methods. The input parameters include the source MAC address, destination MAC address, source MAC address + destination MAC address, source IP address, destination IP address, source IP address + destination IP addresses, source IP address + destination IP address + Layer-4 port number and so on. The algorithm ensures that packets with different input parameters are evenly distributed to member links. It does not indicate that these packets are always distributed to different member links. For example, in IP address-based load balancing, two packets with different source and destination IP addresses may be distributed to the same member link through calculation.

3.3.3 Wireless AP Aggregated Port

Working Principle

If the wireless traffic exceeds gigabit, a single wired port cannot meet the requirements. In this case, an aggregated port needs to be used for load balancing and bandwidth increasing. Wireless APs adopts the dual uplink deployment mode. If a network cable is disconnected, the other cable can continue to work, ensuring link backup. Aggregated port configuration of wireless APs is delivered by the AC or aggregated ports are configured independently on the APs. If wireless APs work in fit AP mode, aggregated port configuration is delivered by the AC. If wireless APs work in fat AP mode, aggregated ports are configured on the AP console over serial ports.

3.4 Configuration

Configuration	Description and Command	
Configuring Static AP Ports	(Mandatory) It is used to configure link aggregation manually.	
	interface aggregateport	Creates an Ethernet AP port.
	port-group	Configures static AP member ports.
Configuring LACP AP Ports	(Mandatory) It is used to configure link aggregation dynamically.	
	port-group mode	Configures LACP member ports.
	lacp system-priority	Configures the LACP system priority.
	lacp port-priority	Configures the port priority.
	lacp short-timeout	Configures the short timeout mode on a port.

Configuration	Description and Command	
Enabling LinkTrap	(Optional) It is used to enable LinkTrap.	
	snmp trap link-status	Enables LinkTrap advertisement for an AP port.
	aggregateport member linktrap	Enables LinkTrap t for AP member ports.
Configuring a Load Balancing Mode	(Optional) It is used to configure a load balancing mode for an aggregated link.	
	aggregateport load-balance	Configures a load balancing algorithm for an AP port or AP member ports.
Configuring Aggregated Port Configuration Delivery from the AC	**ap-interface wireport** *portnumber* **port-group** *apnumber*	Configures aggregated port configuration delivery from the AC.

3.4.1 Configuring Static AP Ports

Configuration Effect

- Configure multiple physical ports as AP member ports to realize link aggregation.
- The bandwidth of the aggregation link is equal to the sum of the member link bandwidths.
- When a member link of the AP port is disconnected, the load carried by the link is automatically allocated to other functional member links.

Notes

- Only physical ports can be added to an AP port.
- The ports of different media types or port modes cannot be added to the same AP port.
- Layer-2 ports can be added to only a Layer-2 AP port, and Layer-3 ports can be added to only a Layer-3 AP port. The Layer-2/3 attributes of an AP port that contains member ports cannot be modified.
- After a port is added to an AP port, the attributes of the port are replaced by those of the AP port.
- After a port is removed from an AP port, the attributes of the port are restored.

After a port is added to an AP port, the attributes of the port are consistent with those of the AP port. Therefore, do not perform configuration on the AP member ports or apply configuration to a specific AP member port. However, some configurations (the **shutdown** and **no shutdown** commands) can be configured on AP member ports. When you use AP member ports, check whether the function that you want to configure can take effect on a specific AP member port, and perform this configuration properly.

Configuration Steps

Creating an Ethernet AP Port

- Mandatory.
- Perform this configuration on an AP-enabled device.

Command	**interface aggregateport** *ap-number*
Parameter Description	*ap-number*: Indicates the number of an AP port.
Defaults	By default, no AP port is created.
Command Mode	Global configuration mode
Usage Guide	To create an Ethernet AP port, run **interfaces aggregateport** in global configuration mode. To delete the specified Ethernet AP port, run **no interfaces aggregateport** *ap-number* in global configuration mode.

Run **port-group** to add a physical port to a static AP port in interface configuration mode. If the AP port does not exist, it will be created automatically.

The AP feature must be configured on the devices at both ends of a link and the AP mode must be the same (static AP or LACP AP).

Configuring Static AP Member Ports

- Mandatory.
- Perform this configuration on AP-enabled devices.

Command	**port-group** *ap-number*
Parameter Description	**port-group** *ap-number*: Indicates the number of an AP port.
Defaults	By default, no ports are added to any static AP port.
Command Mode	Interface configuration mode of the specified Ethernet port
Usage Guide	To add member ports to an AP port, run **port-group** in interface configuration mode. To remove member ports from an AP port, run **no port-group** in interface configuration mode.

The static AP member ports configured on the devices at both ends of a link must be consistent.

After a member port exits the AP port, the default settings of the member port are restored. Different functions deal with the default settings of the member ports differently. It is recommended that you check and confirm the port settings after a member port exits an AP port.

After a member port exits an AP port, the port is disabled by using the **shutdown** command to avoid loops. After you confirm that the topology is normal, run **no shutdown** in interface configuration mode to enable the port again.

Converting Layer-2 APs to Layer-3 APs

- Optional.
- When you need to enable Layer-3 routing on an AP port, for example, to configure IP addresses or static route entries, convert the Layer-2 AP port to a Layer-3 AP port and enable routing on the Layer-3 AP port.
- Perform this configuration on AP-enabled devices that support Layer-2 and Layer-3 features, such as Layer-3 switches or wireless access controllers (ACs).

Command	**no switchport**

Parameter Description	N/A
Defaults	By default, the AP ports are Layer-2 AP ports.
Command Mode	Interface configuration mode of the specified AP port
Usage Guide	The Layer-3 AP feature is supported by only Layer-3 devices.

The AP port created on a Layer-3 device that does not support Layer-2 feature is a Layer-3 AP port. Otherwise, the AP port is a Layer-2 AP port.

Verification

- Run **show running** to display the configuration.
- Run **show aggregateport summary** to display the AP configuration.

Command	**show aggregateport** *aggregate-port-number* [**load-balance | summary**]
Parameter Description	*aggregate-port-number*: Indicates the number of an AP port. **load-balance**: Displays the load balancing algorithm. **summary**: Displays the summary of each link.
Command Mode	Any mode
Usage Guide	The information on all AP ports is displayed if you do not specify the AP port number.
	Ruijie# show aggregateport 1 summary AggregatePort MaxPorts SwitchPort Mode Load balance Ports ---------- ---------- ---------- ------ ---------- ---------- **Ag1** 8 Enabled ACCESS **dst-mac** **Gi0/2**

Configuration Example

Configuring an Ethernet Static AP Port

Scenario **Figure 3-2**	
Configuration Steps	● Add the GigabitEthernet 1/1 and GigabitEthernet 1/2 ports on Switch A to static AP port 3. ● Add the GigabitEthernet 2/1 and GigabitEthernet 2/2 ports on Switch B to static AP port 3.
Switch A	SwitchA# configure terminal SwitchA(config)# interface range GigabitEthernet 1/1-2 SwitchA(config-if-range)# port-group 3

Switch B	SwitchB# configure terminal SwitchB(config)# interface range GigabitEthernet 2/1-2 SwitchB(config-if-range)# port-group 3
Verification	● Run **show aggregateport summary** to check whether AP port 3 contains member ports GigabitEthernet 1/1 and GigabitEthernet 1/2.
Switch A	SwitchA# show aggregateport summary AggregatePort MaxPorts SwitchPort Mode Ports ---------- -------- ---------- ------ ---------- **Ag3** 8 Enabled ACCESS **Gi1/1,Gi1/2**
Switch B	SwitchB# show aggregateport summary AggregatePort MaxPorts SwitchPort Mode Ports ---------- -------- ---------- ------ ---------- **Ag3** 8 Enabled ACCESS **Gi2/1,Gi2/2**

3.4.2 Configuring LACP AP Ports

Configuration Effect

- Connected devices perform autonegotiation through LACP to realize dynamic link aggregation.
- The bandwidth of the aggregation link is equal to the sum of the member link bandwidths.
- When a member link of the AP port is disconnected, the load carried by the link is automatically allocated to other functional member links.
- It takes LACP 90s to detect a link failure in long timeout mode and 3s in short timeout mode.

Notes

- After a port exits an LACP AP port, the default settings of the port may be restored. Different functions deal with the default settings of the member ports differently. It is recommended that you check and confirm the port settings after a member port exits an LACP AP port.
- Changing the LACP system priority may cause LACP member ports to be disaggregated and aggregated again.
- Changing the priority of an LACP member port may cause the other member ports to be disaggregated and aggregated again.

Configuration Steps

↘ **Configuring LACP Member Ports**

- Mandatory.

- Perform this configuration on LACP-enabled devices.

Command	**port-group** *key-number* **mode** { **active | passive** }
Parameter Description	*Key-number*: Indicates the management key of an AP port. In other words, it is the LACP AP port number. The maximum value is subject to the number of AP ports supported by the device. **active**: Indicates that ports are added to a dynamic AP port actively. **passive**: Indicates that ports are added to a dynamic AP port passively.
Defaults	By default, no physical ports are added to any LACP AP port.
Command Mode	Interface configuration mode of the specified physical port
Usage Guide	Use this command in interface configuration mode to add member ports to an LACP AP port.

The LACP member port configuration at both ends of a link must be consistent.

Configuring the LACP System Priority

- Optional.
- Perform this configuration when you need to adjust the system ID priority. A smaller value indicates a higher system ID priority. The device with a higher system ID priority selects an AP port.
- Perform this configuration on LACP-enabled devices.

Command	**lacp system-priority** *system-priority*
Parameter Description	*system-priority*: Indicates the LACP system priority. The value ranges from 0 to 65535.
Defaults	By default, the LACP system priority is 32768.
Command Mode	Global configuration mode
Usage Guide	Use this command in global configuration mode to configure the LACP system priority. All the dynamic member links share one LACP system priority. Changing the LACP system priority will affect all member links. To restore the default settings, run **no lacp system-priority** in interface configuration mode.

Configuring the Priority of an LACP Member Port

- Optional.
- Perform this configuration when you need to specify the port ID priority. A smaller value indicates a higher port ID priority. The port with the highest port ID priority will be selected as the master port.
- Perform this configuration on LACP-enabled devices.

Command	**lacp port-priority** *port-priority*
Parameter Description	*port-priority*: Indicates the priority of an LACP member port. The value ranges from 0 to 65535.
Defaults	By default, the priority of an LACP member port is 32768.
Command Mode	Interface configuration mode of the specified physical port

Usage Guide	Use this command in global configuration mode to configure the priority of an LACP member port. To restore the settings, run **no lacp port-priority** in interface configuration mode.

Configuring the Timeout Mode of LACP Member Ports

- Optional.
- When you need to implement real-time link failure detection, configure the short timeout mode. It takes LACP 90s to detect a link failure in long timeout mode and 3s in short timeout mode.
- Perform this configuration on LACP-enabled devices, such as switches.

Command	**lacp short-timeout**
Parameter Description	N/A
Defaults	By default, the timeout mode of LACP member ports is long timeout.
Command Mode	Interface configuration mode
Usage Guide	The timeout mode is supported only by physical ports. To restore the default settings, run **no lacp short-timeout** in interface configuration mode.

Verification

- Run **show running** to display the configuration.
- Run **show lacp summary** to display LACP link state.

Command	**show lacp summary** [*key-number*]
Parameter Description	*key-name*: Indicates the number of an LACP AP port.
Command Mode	Any mode
Usage Guide	The information on all LACP AP ports is displayed if you do not specify *key-name*.
	Ruijie(config)# show lacp summary 3 System Id:32768, 00d0.f8fb.0002 Flags: S - Device is requesting Slow LACPDUs F - Device is requesting Fast LACPDUs. A - Device is in active mode. 3.4.3 Enabling LinkTrap

Configuration Effect

Enable the system with LinkTrap to send LinkTrap messages when aggregation links are changed.

Configuration Steps

Enabling LinkTrap for an AP Port

- Optional.
- Enable LinkTrap in interface configuration mode. By default, LinkTrap is enabled. LinkTrap messages are sent when the link state or protocol state of the AP port is changed.
- Perform this configuration on AP-enabled devices.

Command	**snmp trap link-status**
Parameter Description	N/A
Defaults	By default, LinkTrap is enabled.
Command Mode	Interface configuration mode of the specified AP port
Usage Guide	Use this command in interface configuration mode to enable LinkTrap for the specified AP port. After LinkTrap is enabled, LinkTrap messages are sent when the link state of the AP port is changed. Otherwise, LinkTrap messages are not sent. By default, LinkTrap is enabled. To disable LinkTrap for an AP port, run **no snmp trap link-status** in interface configuration mode. LinkTrap cannot be enabled for a specific AP member port. To enable LinkTrap for all AP member ports, run **aggregateport member linktrap** in global configuration mode.

Enabling LinkTrap for AP Member Ports

- Optional.
- By default, LinkTrap is disabled for AP member ports.
- Perform this configuration on AP-enabled devices.

Command	**aggregateport member linktrap**
Parameter Description	N/A
Defaults	By default, LinkTrap is disabled for AP member ports.
Command Mode	Global configuration mode
Usage Guide	Use this command in global configuration mode to enable LinkTrap for all AP member ports. By default, LinkTrap messages are not sent when the link state of AP member ports is changed. To disable LinkTrap for all AP member ports, run **no aggregateport member linktrap** in global configuration mode.

Verification

- Run **show running** to display the configuration.
- After LinkTrap is enabled, you can monitor this feature on AP ports or their member ports by using the MIB software.

Configuration Example

Enabling LinkTrap for AP Member Ports

Scenario **Figure 3-3**	Configuration Steps	● Add the GigabitEthernet 1/1 and GigabitEthernet 1/2 ports on Switch A to static AP port 3. ● Add the GigabitEthernet 2/1 and GigabitEthernet 2/2 ports on Switch B to static AP port 3. ● On Switch A, disable LinkTrap for AP port 3 and enable LinkTrap for its member ports. ● On Switch B, disable LinkTrap for AP port 3 and enable LinkTrap its AP member ports.
Switch A	SwitchA# configure terminal SwitchA(config)# interface range GigabitEthernet 1/1-2 SwitchA(config-if-range)# port-group 3 SwitchA(config-if-range)# exit SwitchA(config)# aggregateport member linktrap SwitchA(config)# interface Aggregateport 3 SwitchA(config-if-AggregatePort 3)# no snmp trap link-status
Switch B	SwitchB# configure terminal SwitchB(config)# interface range GigabitEthernet 2/1-2 SwitchB(config-if-range)# port-group 3 SwitchB(config-if-range)# exit SwitchB(config)# aggregateport member linktrap SwitchB(config)# interface Aggregateport 3 SwitchB(config-if-AggregatePort 3)# no snmp trap link-status
Verification	● Run **show running** to check whether LinkTrap is enabled for AP port 3 and its member ports.
Switch A	SwitchA# show run | include AggregatePort 3

	Building configuration... Current configuration: 54 bytes interface AggregatePort 3 no snmp trap link-status SwitchA# show run | include AggregatePort aggregateport member linktrap
Switch B	SwitchB# show run | include AggregatePort 3 Building configuration... Current configuration: 54 bytes interface AggregatePort 3 no snmp trap link-status SwitchB# show run | include AggregatePort aggregateport member linktrap

3.4.4 Configuring a Load Balancing Mode

Configuration Effect

The system distributes incoming packets among member links by using the specified load balancing algorithm. The packet flow with the consistent feature is transmitted by one member link, whereas different packet flows are evenly distributed to various links. A device enabled with enhanced load balancing first determines the type of packets to be transmitted and performs load balancing based on the specified fields in the packets. For example, the AP port performs source IP-based load balancing on the packets containing an ever-changing source IPv4 address.

Notes

N/A

Configuration Steps

↘ **Configuring the Global Load Balancing Algorithm of an AP port**

- (Optional) Perform this configuration when you need to optimize load balancing.
- Perform this configuration on AP-enabled devices.

Command	**aggregateport load-balance** { **dst-mac** | **src-mac** | **src-dst-mac** | **dst-ip** | **src-ip** | **src-dst-ip** | **src-dst-ip-l4port** | **src- l4port** | **dst-l4port** | **src-dst-l4port** | **src-ip-src-l4port** | **src-ip-dst-l4port** | **dst-ip-src-l4port** | **dst-ip-dst-l4port** | **src-ip-src-dst-l4port** | **dst-ip-src-dst-l4port** | **src-dst-ip-src-l4port** | **src-dst-ip-dst-l4port** }
Parameter	**dst-mac**: Indicates that load is distributed based on the destination MAC addresses of incoming packets.

Description	**src-mac**: Indicates that load is distributed based on the source MAC addresses of incoming packets. **src-dst-ip**: Indicates that load is distributed based on source and destination IP addresses of incoming packets. **dst-ip**: Indicates that load is distributed based on the destination IP addresses of incoming packets. **src-ip**: Indicates that load is distributed based on the source IP addresses of incoming packets. **src-dst-mac**: Indicates that load is distributed based on source and destination MAC addresses of incoming packets. **src-dst-ip-l4port**: Indicates that load is distributed based on source IP and destination IP addresses as well as Layer-4 source and destination port numbers. **src- l4port**: Indicates that load is distributed based on Layer-4 source port numbers. **dst- l4port**: Indicates that load is distributed based on Layer-4 destination port numbers. **src-dst-l4port**: Indicates that load is distributed based on Layer-4 source and destination port numbers. **src-ip-src-l4port**: Indicates that load is distributed based on source IP addresses and Layer-4 source port numbers. **src-ip-dst-l4port**: Indicates that load is distributed based on source IP addresses and Layer-4 destination port numbers. **dst-ip-src-l4port**: Indicates that load is distributed based on destination IP addresses and Layer-4 source port numbers. **dst-ip-dst-l4port**: Indicates that load is distributed based on destination IP addresses and Layer-4 destination port numbers. **src-ip-src-dst-l4port:** Indicates that load is distributed based on source IP addresses as well as Layer-4 source and destination port numbers. **dst-ip-src-dst-l4port**: Indicates that load is distributed based on destination IP addresses as well as Layer-4 source and destination port numbers. **src-dst-ip-src-l4port**: Indicates that load is distributed based on source and destination IP addresses as well as Layer-4 source port numbers. **src-dst-ip-dst-l4port**: Indicates that load is distributed based on source and destination IP addresses as well as Layer-4 destination port numbers.
Defaults	Load balancing can be based on source and destination MAC addresses (applicable to switches) or source and destination IP addresses (applicable to gateways).
Command Mode	Global configuration mode
Usage Guide	To restore the default settings, run **no aggregateport load-balance** in global configuration mode. You can run **aggregateport load-balance** in interface configuration mode of an AP port on devices that support load balancing configuration on a specific AP port. The configuration in interface configuration mode prevails. To disable the load balancing algorithm, run **no aggregateport load-balance** in interface configuration mode of the AP port. After that, the load balancing algorithm configured in global configuration mode takes effect.

Verification

- Run **show running** to display the configuration.

- Run **show aggregateport load-balance** to display the load balancing configuration. If a device supports load balancing configuration on a specific AP port, run **show aggregateport summary** to display the configuration.
- Run **show load-balance-profile** to display the enhanced load balancing profile.

Command	**show aggregateport** *aggregate-port-number* [**load-balance | summary**]
Parameter Description	*aggregate-port-number*: Indicates the number of an AP port. **load-balance**: Displays the load balancing algorithm. **summary**: Displays the summary of each link.
Command Mode	Any mode
Usage Guide	The information on All AP ports is displayed if you do not specify the AP port number.
	Ruijie# show aggregateport 1 summary AggregatePort MaxPorts SwitchPort Mode Load balance Ports ---------- ---------- ---------- ------ ---------- ---------- **Ag1** 8 Enabled ACCESS **dst-mac** **Gi0/2**

Configuration Example

Configuring a Load Balancing Mode

Scenario **Figure 3-4**	
Configuration Steps	● Add the GigabitEthernet 1/1 and GigabitEthernet 1/2 ports on Switch A to static AP port 3. ● Add the GigabitEthernet 2/1 and GigabitEthernet 2/2 ports on Switch B to static AP port 3. ● On Switch A, configure source MAC address-based load balancing for AP port 3 in global configuration mode. ● On Switch B, configure destination MAC address-based load balancing for AP port 3 in global configuration mode.
Switch A	SwitchA# configure terminal SwitchA(config)# interface range GigabitEthernet 1/1-2 SwitchA(config-if-range)# port-group 3 SwitchA(config-if-range)# exit SwitchA(config)# aggregateport load-balance src-mac

Switch B	SwitchB# configure terminal SwitchB(config)# interface range GigabitEthernet 2/1-2 SwitchB(config-if-range)# port-group 3 SwitchB(config-if-range)# exit SwitchB(config)# aggregateport load-balance dst-mac
Verification	● Run **show aggregateport load-balance** to check the load balancing algorithm configuration.
Switch A	SwitchA# show aggregatePort load-balance Load-balance : **Source MAC**
Switch B	SwitchB# show aggregatePort load-balance Load-balance : **Destination MAC**

Common Errors

N/A

3.4.5 Configuring Aggregated Port Configuration Delivery from the AC

Configuration Effect

- After the AC delivers the aggregated port configuration to the AP, the corresponding wired port on the AP will be added to or exit from the corresponding aggregated port.

Notes

- To ensure normal link aggregation, static AP member ports need to be configured consistently on the two devices over a link.
- After an AP member port is added to an aggregated port, the member port cannot be added to other aggregated ports. The member port can be added to another aggregated port only after it exits from the original AP port.

Configuration Steps

↘ **Configuring Aggregated Port Configuration Delivery from the AC**

- Optional
- Perform this operation when a wired port of a specific AP, AP group, or all APs needs to be added to the AP aggregation group.

Command	**ap-interface wireport** *port-number* **port-group** *ap-number*
Parameter Description	**port-number**: Indicates the ID of the wired port on the AP. **ap-number**: Indicates the ID of the AP port.
Defaults	By default, the AC does not deliver aggregation port configuration.

Command Mode	ap-configure and ap-group configuration mode
Usage Guide	In ap-config and ap-group configuration mode, run **ap-interface wireport** *port-number* **port-group** *ap-number* to deliver an aggregated port configuration to enable a wired port on the AP to be added to the AP aggregation group, and run **no ap-interface wireport** *port-number* **port-group** for a specific wired port to exit from the AP aggregation group.

Verification

- Run **show running** to query the corresponding configuration.
- Run **show aggregateport summery** to query the corresponding relationship between the aggregated port and AP member ports.

Command	**show aggregateport summery**
Parameter Description	**ap-num**: Indicates the AP number.
Command Mode	All modes
Usage Guide	-
Command Presentation	Ruijie# show aggregateport summary AggregatePort MaxPorts Ports ---------- -------- ---------- Ag1 8 Gi0/1,Gi0/2

3.5 Monitoring

Displaying

Description	Command
Displays the summary or load balancing algorithm of an AP port.	**show aggregateport** [*ap-number*] { **load-balance** | **summary** }

Debugging

⚠ System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs an AP port.	**debug lsm ap**

4 Configuring VLAN

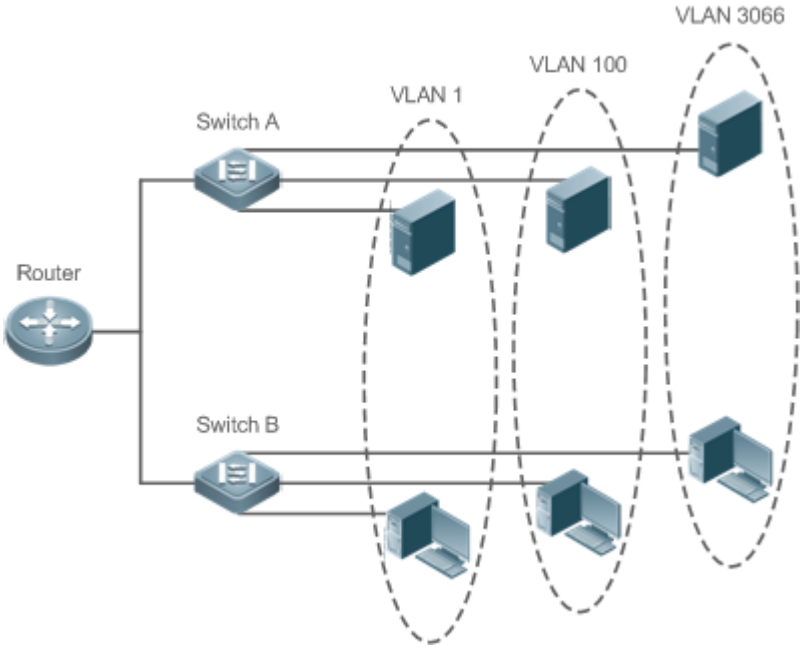
4.1 Overview

A Virtual Local Area Network (VLAN) is a logical network created based on a physical network. A VLAN can be categorized into Layer-2 networks of the OSI model.

A VLAN has the same properties as a common LAN, except for physical location limitation. Unicast, broadcast and multicast frames of Layer 2 are forwarded and transmitted within a VLAN, keeping traffic segregated.

We may define a port as a member of a VLAN, and all terminals connected to this port are parts of a virtual network that supports multiple VLANs. You do not need to adjust the network physically when adding, removing and modifying users. Communication among VLANs is realized through Layer-3 devices, as shown in the following figure.

Figure 4-1



Protocols and Standards

- IEEE 802.1Q

4.2 Applications

N/A

4.3 Features

Basic Concepts

VLAN

A VLAN is a logical network created based on a physical network. A VLAN has the same properties as a common LAN, except for physical location limitation. Unicast, broadcast and multicast frames of Layer 2 are forwarded and transmitted within a VLAN, keeping traffic segregated.

- The VLANs supported by Ruijie products comply with the IEEE802.1Q standard. A maximum of 4094 VLANs (VLAN ID 1-4094) are supported, among which VLAN 1 cannot be deleted.
- The configurable VLAN IDs are from 1 to 4094.
- In case of insufficient hardware resources, the system returns information on VLAN creation failure.

Port Mode

You can determine the frames allowed to pass a port and the VLANs which the port belongs to by configuring the port mode. See the following table for details.

Port Mode	Description
Access port	An Access port belongs to only one VLAN, which is specified manually.
Trunk port (802.1Q)	A Trunk port belongs to all the VLANs of an access switch by default, and it can forward the frames of all the VLANs or the frames of allowed-VLANs.
Uplink port	An Uplink port belongs to all the VLANs of an access switch by default, and it can forward the frames of all the VLANs and tag the native VLAN egress traffic.
Hybrid port	A Hybrid port belongs to all the VLANs of an access switch by default, and it can forward the frames of all the VLANs and send frames of VLANs untagged. It can also transmit frames of allowed-VLANs.

Overview

Feature	Description
VLAN	VLAN helps realize Layer-2 isolation.

4.3.1 VLAN

Every VLAN has an independent broadcast domain, and different VLANs are isolated on Layer 2.

Working Principle

Every VLAN has an independent broadcast domain, and different VLANs are isolated on Layer 2.

Layer-2 isolation: If no SVIs are configured for VLANs, VLANs are isolated on Layer 2. This means users in these VLANs cannot communicate with each other.

Layer-3 interconnection: If SVIs are configured on a Layer-3 switch for VLANs, these VLANs can communicate with each other on Layer 3.

4.4 Configuration

Configuration	Description and Command	
Configuring Basic VLAN	(Mandatory) It is used to create a VLAN.	
	vlan	Enters a VLAN ID.
	(Optional) It is used to configure an Access port to transmit the flows from a single VLAN.	
	switchport mode access	Defines a port as a Layer-2 Access port.
	switchport access vlan	Assigns a port to a VLAN.
	add interface	Adds one Access port or a group of such ports to the current VLAN.
	(Optional) It is used to rename a VLAN.	
	name	Names a VLAN.
Configuring a Trunk Port	(Mandatory) It is used to configure the port as a Trunk port.	
	switchport mode trunk	Defines a port as a Layer-2 Trunk port.
	(Optional) It is used to configure Trunk ports to transmit flows from multiple VLANs.	
	switchport trunk allowed vlan	Configures allowed-VLANs for a Trunk port.
	switchport trunk native vlan	Specifies a native VLAN for a Trunk port.
Configuring an Uplink Port	(Mandatory) It is used to configure the port as an Uplink port.	
	switchport mode uplink	Configures a port as an Uplink port.
	(Optional) It is used to restore the port mode.	
	no switchport mode	Restores the port mode.
Configuring a Hybrid Port	(Mandatory) It is used to configure a port as a Hybrid port.	
	switchport mode hybrid	Configures a port as a Hybrid port.
	(Optional) It is used to transmit the frames of multiple VLANs untagged.	
	no switchport mode	Restores the port mode.
	switchport hybrid allowed vlan	Configures allowed-VLANs for a Hybrid port.
	switchport hybrid native vlan	Configures a default VLAN for a Hybrid port.

4.4.1 Configuring Basic VLAN

Configuration Effect

- A VLAN is identified by a VLAN ID. You may add, delete, modify VLANs 2 to 4094, but VLAN 1 is created automatically and cannot be deleted. You may configure the port mode, and add or remove a VLAN.

Notes

- N/A

Configuration Steps

↘ Creating and Modifying a VLAN

- Mandatory.
- In case of insufficient hardware resources, the system returns information on VLAN creation failure.
- Use the vlan vlan-id command to create a VLAN or enter VLAN mode.

Command	**vlan** *vlan-id*
Parameter Description	*vlan-id*: indicates VLAN ID ranging from 1 to 4094.
Defaults	VLAN 1 is created automatically and is not deletable.
Command Mode	Global configuration mode
Usage Guide	If you enter a new VLAN ID, the corresponding VLAN will be created. If you enter an existing VLAN ID, the corresponding VLAN will be modified. You may use the **no vlan** *vlan-id* command to delete a VLAN. The undeletable VLANs include VLAN1, the VLANs configured with SVIs, and SubVLANs.

↘ Renaming a VLAN

- Optional.
- You cannot rename a VLAN the same as the default name of another VLAN.
- Configuration:

Command	**name** *vlan-name*
Parameter Description	*vlan-name*: indicates a VLAN name.
Defaults	By default, the name of a VLAN is its VLAN ID. For example, the default name of the VLAN 4 is VLAN 0004.
Command Mode	VLAN configuration mode
Usage Guide	To restore the VLAN name to defaults, use the **no name** command.

↘ Assigning Current Access port to a Specified VLAN

- Optional.

- Use the **switchport mode access** command to specify Layer-2 ports (switch ports) as Access ports.
- Use the **switchport access vlan** *vlan-id* command to add an Access port to a specific VLAN so that the flows from the VLAN can be transmitted through the port.

Command	**switchport mode access**
Parameter Description	N/A
Defaults	A switch port is an Access port by default.
Command Mode	Interface configuration mode
Usage Guide	N/A

Command	**switchport access vlan** *vlan-id*
Parameter Description	*vlan-id*: indicates a VLAN ID.
Defaults	An Access port is added to VLAN 1 by default.
Command Mode	Interface configuration mode
Usage Guide	If a port is assigned to a non-existent VLAN, the VLAN will be created automatically.

Adding an Access Port to Current VLAN

- Optional.
- This command takes effect only on an Access port. After an Access port is added to a VLAN, the flows of the VLAN can be transmitted through the port.

Command	**add interface** { *interface-id* | **range** *interface-range* }
Parameter Description	*interface-id*: indicates a single port. *interface-id*: indicates multiple ports.
Defaults	By default, all Layer-2 Ethernet ports belong to VLAN 1.
Command Mode	VLAN configuration mode
Usage Guide	In VLAN configuration mode, add a specific Access port to a VLAN. This command takes the same effect as command **switchport access vlan** *vlan-id*.

For the two commands of adding a port to a VLAN, the command configured later will overwrite the other one.

Verification

- Send untagged packets to an Access port, and they are broadcast within the VLAN.
- Use commands **show vlan** and **show interface switchport** to check whether the configuration takes effect.

Command	**show vlan** [**id** *vlan-id*]
Parameter Description	*vlan-id* **:** indicates a VLAN ID.
Command Mode	Any mode
Usage Guide	N/A
Command Display	`Ruijie(config-vlan)#show vlan id 20` `VLAN Name Status Ports` `---- -------------------------------- --------- -----------------------------------` `20 VLAN0020 STATIC Gi0/1`

Configuration Example

Configuring Basic VLAN and Access Port

Configuration Steps	• Create a VLAN and rename it. • Add an Access port to the VLAN. There are two approaches. One is:
	`Ruijie# configure terminal` `Ruijie(config)# vlan 888` `Ruijie(config-vlan)# name test888` `Ruijie(config-vlan)# configure terminal` `Ruijie(config)# interface GigabitEthernet 0/3` `Ruijie(config-if-GigabitEthernet 0/3)# switchport mode access`

	Ruijie(config-if-GigabitEthernet 0/3)# switchport access vlan 20 The other approach is adding an Access port (GigabitEthernet 0/3) to VLAN20: Ruijie# configure terminal SwitchA(config)#vlan 20 SwitchA(config-vlan)#add interface GigabitEthernet 0/3
Verification	Check whether the configuration is correct.
	Ruijie(config-vlan)#show vlan VLAN Name Status Ports ---- -------------------------------- --------- ---------------------------------- 1 VLAN0001 STATIC **20 VLAN0020 STATIC Gi0/3** **888 test888 STATIC** Ruijie(config-vlan)# Ruijie# show interface GigabitEthernet 0/3 switchport Interface Switchport Mode Access Native Protected VLAN lists -------------------------------- ---------- --------- ------ ------ --------- -------------- GigabitEthernet 0/3 **enabled ACCESS 20 1 Disabled ALL**

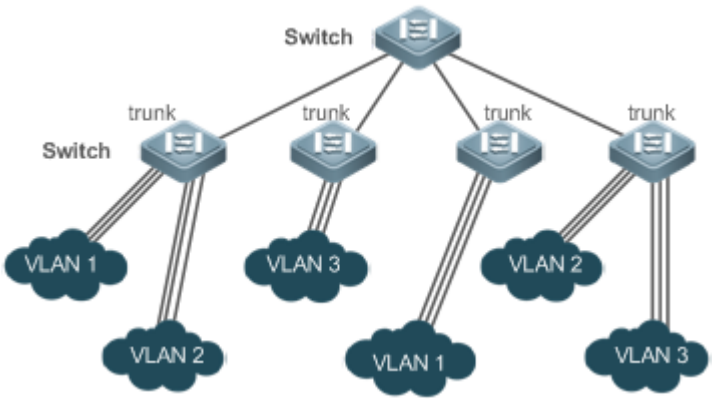
4.4.2 Configuring a Trunk Port

Configuration Effect

A Trunk is a point-to-point link connecting one Ethernet interface or multiple ones to other network devices (for example, a router or switch) and it may transmit the flows from multiple VLANs.

The Trunk of Ruije devices adopts the 802.1Q encapsulation standard. The following figure displays a network adopting a Trunk connection.

Figure 4-2



You may configure an Ethernet port or Aggregate Port (See *Configuring Aggregate Port* for details) as a Trunk port.

You should specify a native VLAN for a Trunk port. The untagged packets received by and sent from the Trunk port are considered to belong to the native VLAN. The default VLAN ID (PVID in the IEEE 802.1Q) of this Trunk port is the native VLAN ID. Meanwhile, frames of the native VLAN sent via the Trunk are untagged. The default native VLAN of a Trunk port is VLAN 1.

When configuring a Trunk link, make sure the Trunk ports at the two ends of the link adopt the same native VLAN.

Configuration Steps

Configuring a Trunk Port

- Mandatory.
- Configure a Trunk port to transmit the flows from multiple VLANs.

Command	**switchport mode trunk**
Parameter Description	N/A
Defaults	The default mode is Access, which can be modified to Trunk.
Command Mode	Interface configuration mode
Usage Guide	To restore all properties of a Trunk port to defaults, use the **no switchport mode** command.

Defining Allowed-VLANs for a Trunk Port

- Optional.
- By default, a trunk port transmits the flows from all the VLANs (1 to 4094). You may configure a list of allowed-VLANs to prohibit flows of some VLANs from passing through a Trunk port.

Command	**switchport trunk allowed vlan** { **all** | [**add** | **remove** | **except** | **only**] } *vlan-list*
Parameter Description	The parameter vlan-list can be a VLAN or some VLANs, and the VLAN IDs are connected by "-" in order. For example: 10–20. **all** indicates allowed-VLANs include all VLANs; **add** indicates adding a specific VLAN to the list of allowed-VLANs; **remove** indicates removing a specific VLAN from the list of allowed-VLANs; **except** indicates adding all VLANs except those in the listed VLAN to the list of allowed-VLANs. **only** indicates adding the listed VLANs to the list of allowed-VLANs, and removing the other VLANs from the list.
Defaults	The Trunk port and the Uplink port belong to all VLANs.
Command Mode	Interface configuration mode
Usage Guide	To restore the configuration on a Trunk port to defaults (**all**), use the **no switchport trunk allowed vlan** command.

Configuring a Native VLAN

- Optional.
- A Trunk port receives and sends tagged or untagged 802.1Q frames. Untagged frames transmit the flows from the native VLAN. The default native VLAN is VLAN 1.
- If a frame carries the VLAN ID of a native VLAN, its tag will be stripped automatically when it passes a Trunk port.

Command	**switchport trunk native vlan** *vlan-id*
Parameter Description	*vlan-id*: indicates a VLAN ID.
Defaults	The default VALN for a Trunk/Uplink port is VLAN 1.
Command Mode	Interface configuration mode
Usage Guide	To restore the native VLAN of a Trunk port back to defaults, use the **no switchport trunk native vlan** command.

When you set the native VLAN of a port to a non-existent VLAN, this VLAN will not be created automatically. Besides, the native VLAN can be out of the list of allowed-VLANs for this port. In this case, the flows from the native VLAN cannot pass through the port.

Verification

- Send tag packets to a Trunk port, and they are broadcast within the specified VLANs.

- Use commands **show vlan** and **show interface switchport** to check whether the configuration takes effect.

Command	**show vlan** [**id** *vlan-id*]
Parameter Description	*vlan-id* **:** indicates a VLAN ID.
Command Mode	Any mode
Usage Guide	N/A
Command Display	Ruijie(config-vlan)#show vlan id 20 VLAN Name Status Ports ---- -------------------------------- --------- ------------------------------- **20 VLAN0020 STATIC Gi0/1**

Configuration Example

- N/A

Common Errors

- N/A

4.4.3 Configuring an Uplink Port

Configuration Effect

- An Uplink port is usually used in QinQ (the IEEE 802.1ad standard) environment, and is similar to a Trunk port. Their difference is that an Uplink port only transmits tagged frames while a Trunk port sends untagged frames of the native VLAN.

Configuration Steps

Configuring an Uplink Port

- Mandatory.
- Configure an Uplink port to transmit the flows from multiple VLANS, but only tagged frames can be transmitted.

Command	**switchport mode uplink**
Parameter Description	N/A
Defaults	The default mode is Access, which can be modified to Uplink.
Command Mode	Interface configuration mode
Usage Guide	To restore all properties of an Uplink port to defaults, use the **no switchport mode** command.

Defining Allowed-VLANs for a Trunk Port

- Optional.

- You may configure a list of allowed-VLANs to prohibit flows of some VLANs from passing through an Uplink port.

Command	**switchport trunk allowed vlan** { **all** | [**add** | **remove** | **except** | **only**] } *vlan-list*
Parameter Description	The parameter *vlan-list* can be a VLAN or some VLANs, and the VLAN IDs are connected by "-" in order. For example: 10–20. **all** indicates allowed-VLANs include all VLANs; **add** indicates adding a specific VLAN to the list of allowed-VLANs; **remove** indicates removing a specific VLAN from the list of allowed-VLANs; **except** indicates adding all VLANs except those in the listed VLAN to the list of allowed-VLANs; and **only** indicates adding the listed VLANs to the list of allowed-VLANs, and removing the other VLANs from the list.
Command Mode	Interface configuration mode
Usage Guide	To restore the allowed-VLANs to defaults (**all**), use the **no switchport trunk allowed vlan** command.

Configuring a Native VLAN

- Optional.
- If a frame carries the VLAN ID of a native VLAN, its tag will not be stripped when it passes an Uplink port. This is contrary to a Trunk port.

Command	**switchport trunk native vlan** *vlan-id*
Parameter Description	*vlan-id*: indicates a VLAN ID.
Command Mode	Interface configuration mode
Usage Guide	To restore the native VLAN of an Uplink to defaults, use the **no switchport trunk native vlan** command.

Verification

- Send tag packets to an Uplink port, and they are broadcast within the specified VLANs.
- Use commands **show vlan** and **show interface switchport** to check whether the configuration takes effect.

Command	**show vlan** [**id** *vlan-id*]
Parameter Description	*vlan-id* **:** indicates a VLAN ID.
Command Mode	Any mode
Usage Guide	N/A
Command Display	Ruijie(config-vlan)#show vlan id 20 VLAN Name Status Ports ---- -------------------------------- --------- ----------------------------------- **20 VLAN0020 STATIC Gi0/1**

Configuration Example

Configuring an Uplink Port

Configuration Steps	The following is an example of configuring Gi0/1 as an Uplink port.
	Ruijie# configure terminal Ruijie(config)# interface gi 0/1 Ruijie(config-if-GigabitEthernet 0/1)# switchport mode uplink Ruijie(config-if-GigabitEthernet 0/1)# end
Verification	Check whether the configuration is correct.
	Ruijie# show interfaces GigabitEthernet 0/1 switchport Interface Switchport Mode Access Native Protected VLAN lists GigabitEthernet 0/1 enabled UPLINK 1 1 disabled ALL

4.4.4 Configuring a Hybrid Port

Configuration Effect

- A Hybrid port is usually used in SHARE VLAN environment. By default, a Hybrid port is the same as a Trunk port. Their difference is that a Hybrid port can send the frames from the VLANs except the default VLAN in the untagged format.

Configuration Steps

Configuring a Hybrid Port

- Mandatory.
- Configure a Hybrid port to transmit the flows from multiple VLANs.

Command	**switchport mode hybrid**
Parameter Description	N/A
Defaults	The default mode is Access, which can be modified to Hybrid.
Command Mode	Interface configuration mode
Usage Guide	To restore all properties of a Hybrid port to defaults, use the **no switchport mode** command.

Defining Allowed-VLANs for a Hybrid Port

- Optional.
- By default, a Hybrid port transmits the flows from all the VLANs (1 to 4094). You may configure a list of allowed-VLANs to prohibit flows of some VLANs from passing through a Hybrid port.

Command	**switchport hybrid allowed vlan** [[**add** | **only**] **tagged** | [**add**] **untaged** | **remove**] *vlan_list*
Parameter Description	*vlan-id*: indicates a VLAN ID.
Defaults	By default a Hybrid port belongs to all VLANs. The port is added to the default VLAN in untagged form and to the other VLANs in the tagged form.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring a Native VLAN

- Optional.
- If a frame carries the VLAN ID of a native VLAN, its tag will be stripped automatically when it passes a Hybrid port.

Command	**switchport hybrid native vlan** *vlan_id*
Parameter Description	*vlan-id*: indicates a VLAN ID.
Defaults	The default native VLAN is VLAN 1.
Command Mode	Interface configuration mode
Usage Guide	To restore the native VLAN of a Hybrid port to defaults, use the **no switchport hybrid native vlan** command.

Verification

- Send tagged packets to an Hybrid port, and they are broadcast within the specified VLANs.
- Use commands **show vlan** and **show interface switchport** to check whether the configuration takes effect.

Command	**show vlan** [**id** *vlan-id*]
Parameter Description	*vlan-id* **:** indicates a VLAN ID.
Command Mode	Any mode
Usage Guide	N/A
Command Display	Ruijie(config-vlan)#show vlan id 20 VLAN Name Status Ports ---- -------------------------------- --------- ----------------------------------- **20 VLAN0020 STATIC Gi0/1**

Configuration Example

Configuring a Hybrid Port

Configuration Steps	The following is an example of configuring Gi0/1 as a Hybrid port.

	Ruijie# configure terminal Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# switchport mode hybrid Ruijie(config-if-GigabitEthernet 0/1)# switchport hybrid native vlan 3 Ruijie(config-if-GigabitEthernet 0/1)# switchport hybrid allowed vlan untagged 20-30 Ruijie(config-if-GigabitEthernet 0/1)# end
Verification	Check whether the configuration is correct.
	Ruijie(config-if-GigabitEthernet 0/1)#show run interface gigabitEthernet 0/1 Building configuration... Current configuration : 166 bytes interface GigabitEthernet 0/1 switchport switchport mode **hybrid** switchport hybrid **native vlan 3** switchport hybrid allowed vlan add **untagged 20-30**

5 Configuring Super VLAN

5.1 Overview

Super virtual local area network (VLAN) is an approach to dividing VLANs.Super VLAN is also called VLAN aggregation, and is a management technology tailored for IP address optimization.

Using super VLAN can greatly save IP addresses. Only one IP address needs to be assigned to the super VLAN that consists of multiple sub VLANs, which greatly saves IP addresses and facilitates network management.

5.2 Application

Application	Description
Sharing One IP Gateway Among Multiple VLANs	VLANs are divided to implement layer-2 (L2) isolation of access users. All VLAN users share one IP gateway to implement layer-3 (L3) communication and communication with external networks.

5.2.1 Sharing One IP Gateway Among Multiple VLANs

Scenario

Multiple VLANs are isolated at L2 on a L3 device, but users of these VLANs can perform L3 communication with each other in the same network segment.

Deployment

On the intranet, use the super VLAN so that multiple sub VLANs can share one IP gateway and meanwhile VLANs are mutually isolated at L2.

Users in sub VLANs can perform L3 communication through the gateway of the super VLAN.

5.3 Features

Basic Concepts

↘ Super VLAN

Super VLAN is also called VLAN aggregation, and is a management technology tailored for IP address optimization. It aggregates multiple VLANs to one IP network segment. No physical port can be added to a super VLAN. The switch virtual interface (SVI) is used to manage the cross-VLAN communication of sub VLANs. The super VLAN cannot be used as a common 802.1Q VLAN, but can be treated as the primary VLAN of sub VLANs.

Sub VLAN

A sub VLAN is an independent broadcast domain. Sub VLANs are mutually isolated at L2. Users of sub VLANs of the same or different super VLANs communicate with each other through the L3 SVIs of their own super VLANs.

ARP Proxy

A L3 SVI can be created only for a super VLAN. Users in a sub VLAN communicates with users in other sub VLANs of the same super VLAN or users in other network segments through the ARP proxy and the L3 SVI of the super VLAN. When a user of a sub VLAN sends an ARP request to a user of another sub VLAN, the gateway of the super VLAN uses its own MAC addressto send or respond to the ARP requests. The process is called ARP proxy.

IP Address Range of the Sub VLAN

Based on the gateway IP address configured for the super VLAN, an IP address range can be configured for each sub VLAN.

Overview

Feature	Description
Super VLAN	Create a L3 interface as anSVI to allow all sub VLANs to share the same IP network segment through the ARP proxy.

5.3.1 Super VLAN

Users of all sub VLANs of a super VLAN can be allocated IP addresses in the same IP address range, and share the same IP gateway. Users can implement cross-VLAN communication through this gateway. It is unnecessary to allocate a gateway for every VLAN, which saves the IP addresses.

Working Principle

IP addresses in a network segment are allocated to different sub VLANs that belong to the same super VLAN. Each sub VLAN has an independent broadcast domain of the VLAN, and different sub VLANs are isolated from each other at L2. When users in sub VLANs need to perform L3 communication, the IP address of the SVI of the super VLAN is used as the gateway address. In this way, multiple VLANs share the same IP gateway, and it is unnecessary to configure a gateway for every VLAN. In addition, to implement L3 communication between sub VLANs and between sub VLANs and other network segments, the ARP proxy function is used to forward and process the ARP requests and responses.

L2 communication of sub VLANs: If the SVI is not configured for the super VLAN, sub VLANs of super VLAN are mutually isolated at L2, that is, users in different sub VLANs cannot communicate with each other. If the SVI is configured for the super VLAN, and the gateway of the super VLAN can function as the ARP proxy, users in different sub VLANs of the same super VLAN can communicate with each other. This is because IP addresses of users in different sub VLANs belong to the same network segment, and communication between these users is still treated as L2 communication.

L3 communication of sub VLANs: If users in sub VLANs of a super VLAN need to perform L3 communication across network segments, the gateway of this super VLAN functions as the ARP proxy to respond to the ARP requests in place of sub VLANs.

5.4 Configuration

Configuration Item	Description and Command	
Configuring Basic Functions of the Super VLAN	Mandatory.	
	supervlan	Configures a super VLAN.
	subvlan*vlan-id-list*	Configures a sub VLAN.
	proxy-arp	Enables the ARP proxy function.
	interface vlan*vlan-id*	Creates a virtual interface for a super VLAN.
	ip address*ip mask*	Configures the IP address of the virtual interface of a super VLAN.
	Optional.	
	subvlan-address-range *start-ip end-ip*	Specifies the IP address range in a sub VLAN.

5.4.1 Configuring Basic Functions of the Super VLAN

Configuration Effect

Enable the super VLAN function and configure an SVI for the super VLAN to implement L2/L3 communication between sub VLANs across VLANs.

Users in all sub VLANs of a super VLAN share the same IP gateway. It is unnecessary to specify a network segment for every VLAN, which saves the IP addresses.

Notes

- A super VLAN does not belong to any physical port. Therefore, the device configured with the super VLAN cannot process packets that contain the super VLAN tag.
- Both the super VLAN function and the ARP proxy function of each sub VLAN must be enabled.
- An SVI and an IP address must be configured for a super VLAN. The SVI is a virtual interface used for communication of users in all sub VLANs.

Configuration Steps

Configuring a Super VLAN

- Mandatory.
- No physical port exists in a super VLAN.
- The ARP proxy function must be enabled. This function is enabled by default.

A super VLAN is valid only after you configure sub VLANs for this super VLAN.

VLAN 1 cannot be configured as a super VLAN.

A super VLAN cannot be configured as a sub VLAN of another super VLAN. A sub VLAN of a super VLAN cannot be configured as a super VLAN.

Command	**supervlan**
Parameter Description	N/A
Defaults	N/A
Command Mode	VLAN configuration mode
Usage Guide	By default, the super VLAN function is disabled. No physical port can be added to a super VLAN. Once a VLAN is not a super VLAN, all its sub VLANs become common static VLANs.

Configuring a Virtual Interface for a Super VLAN

- Mandatory.
- No physical port can be added to a super VLAN. You can configure the L3 SVI for a VLAN.

When a super VLAN is configure with an SVI, it allocates a L3 interface i to each sub VLANs. If a sub VLAN is not allocated a L3 interfacedue to resource deficiency, the sub VLAN becomes a common VLAN again.

Command	**interface vlan***vlan-id*
Parameter Description	*vlan-id*: Indicates the ID of the super VLAN.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	A L3 interface must be configured as the virtual interface of a super VLAN.

Configuring the Gateway of a Super VLAN

- Mandatory.
- The IP gateway on the L3 SVI is configured as the proxy for all users in sub VLANs to respond to ARP requests.

Command	**ip address***ip mask*
Parameter Description	*ip*: Indicates the IP address of the gateway on the virtual interface of a super VLAN. *Mask*: Indicates the mask.
Defaults	N/A
Command Mode	Interface configuration mode
Usage Guide	Run this command to configure the gateway for a super VLAN. Users of all sub VLANs of the super VLAN

	share this gateway.

Configuring a Sub VLAN

- Mandatory.
- Physical ports can be added to sub VLANs. Sub VLANs of a super VLAN share the gateway address of the super VLAN and reside in the same network segment.
- The ARP proxy function must be enabled. This function is enabled by default.

You must change a sub VLAN into a common VLAN before you can delete this sub VLAN by running the **no vlan** command.

One sub VLAN belongs to only one super VLAN.

Command	**subvlan***vlan-id-list*
Parameter Description	*vlan-id-list* : Specifies multiple VLANs as sub VLANs of a super VLAN.
Defaults	N/A
Command Mode	VLAN configuration mode
Usage Guide	Connection interfaces can be added to a sub VLAN. You must change a sub VLAN into a common VLAN before you can delete this sub VLAN by running the **no vlan** [*id*]command. You cannot configure a L3 SVI of the VLAN for a sub VLAN. If you have configured a L3 SVI for a super VLAN, the attempt of adding more sub VLANs may fail due to resource deficiency. If you configure sub VLANs to a super VLAN, and then configure a L3 SVI of the VLAN for a super VLAN, some sub VLANs may become common VLANs again due to resource deficiency.

Configuring the ARP Proxy

- (Mandatory) The ARP proxy function is enabled by default.
- Users in sub VLANs can implement L2/L3 communication across VLANs through the gateway proxy only after the ARP proxy function is enabled on both the super VLAN and sub VLANs.

The ARP proxy function must be enabled on both the super VLAN and sub VLANs.Otherwise, this function does not take effect.

Command	**proxy-arp**
Parameter Description	N/A
Defaults	N/A
Command Mode	VLAN configuration mode

Usage Guide	By default, the ARP proxy function is enabled. Run this command to enable the ARP proxy function on both the super VLAN and sub VLANs. Users in sub VLANs can implement L2/L3 communication across VLANs only after the ARP proxy function is enabled on both the super VLAN and sub VLANs.

Configuring the IP Address Range of the Sub VLAN

- You can allocate an IP address range to each sub VLAN. Users in a sub VLAN can communicate with users of other VLANs only when their IP addresses are in the specified range.
- Unless otherwise specified, you do not need to configure the IP address range.

IP addresses dynamically allocated to users through DHCP may not be in the allocated IP address range. If the IP addresses allocated through DCHP are not in the specified range, users in a sub VLAN cannot communicate with users of other VLANs. Therefore, be cautious in using the **subvlan-address-range** *start-ip end-ip*command.

The IP address range of a sub VLAN must be within the IP address range of the super VLAN to which the sub VLAN belongs.Otherwise, users in sub VLANs cannot communicate with each other.

IP addresses of users in a sub VLAN must be within the IP address range of the sub VLAN.Otherwise, users in the sub VLAN cannot communicate with each other.

Command	**subvlan-address-range** *start-ip end-ip*
Parameter Description	*start-ip*: Indicates the start IP address of a sub VLAN. *end-ip*: Indicates the end IP address of a sub VLAN.
Defaults	N/A
Command Mode	VLAN configuration mode
Usage Guide	Optional. Run this command to configure the IP address range of users in a sub VLAN. IP address ranges of different sub VLANs of a super VLAN cannot overlap with each other. The IP address range of a sub VLAN must be within the IP address range of the super VLAN to which the sub VLAN belongs. Otherwise, users in sub VLANs cannot communicate with each other. Users in a sub VLAN can communicate with users of other VLANs only when their IP addresses (either dynamically allocated through DHCP or statically configured) are in the configured IP address range. IP addresses allocated through DHCP may not be in the configured IP address range. In this case, users in a sub VLAN cannot communicate with users of other VLANs. Therefore, be cautious when using this command.

Verification

After each sub VLAN is correlated with the gateway of the super VLAN, users in sub VLANs can ping each other.

Configuration Example

- N/A

Common Errors

The SVI and IP gateway are not configured for the super VLAN. Consequently, communication fails between sub VLANs and between sub VLANs and other VLANs.

The ARP proxy function is disabled on the super VLAN or sub VLANs. Consequently, users in sub VLANs cannot communicate with users of other VLANs.

The IP address range of the sub VLAN is configured, but IP addresses allocated to users are not in this range.

5.5 Monitoring

Debugs the super VLAN.	**debug bridge svlan**

6 Configuring MSTP

6.1 Overview

Spanning Tree Protocol (STP) is a Layer-2 management protocol. It cannot only selectively block redundant links to eliminate Layer-2 loops but also can back up links.

Similar to many protocols, STP is continuously updated from Rapid Spanning Tree Protocol (RSTP) to Multiple Spanning Tree Protocol (MSTP) as the network develops.

For the Layer-2 Ethernet, only one active link can exist between two local area networks (LANs). Otherwise, a broadcast storm will occur. To enhance the reliability of a LAN, it is necessary to establish a redundant link and keep some paths in backup state. If the network is faulty and a link fails, you must switch the redundant link to the active state. STP can automatically activate the redundant link without any manual operations. STP enables devices on a LAN to:

- Discover and start the best tree topology on the LAN.
- Troubleshoot a fault and automatically update the network topology so that the possible best tree topology is always selected.

The LAN topology is automatically calculated based on a set of bridge parameters configured by the administrator. The best topology tree can be obtained by properly configuring these parameters.

RSTP is completely compatible with 802.1D STP. Similar to traditional STP, RSTP provides loop-free and redundancy services. It is characterized by rapid speed. If all bridges in a LAN support RSTP and are properly configured by the administrator, it takes less than 1 second (about 50 seconds if traditional STP is used) to re-generate a topology tree after the network topology changes.

STP and RSTP have the following defects:

- STP migration is slow. Even on point-to-point links or edge ports, it still takes two times of the forward delay for ports to switch to the forwarding state.
- RSTP can rapidly converge but has the same defect with STP: Since all VLANs in a LAN share the same spanning tree, packets of all VLANs are forwarded along this spanning tree. Therefore, redundant links cannot be blocked according to specific VLANs and data traffic cannot be balanced among VLANs.

MSTP, defined by the IEEE in 802.1s, resolves defects of STP and RSTP. It cannot only rapidly converge but also can enable traffic of different VLANs to be forwarded along respective paths, thereby providing a better load balancing mechanism for redundant links.

In general, STP/RSTP works based on ports while MSTP works based on instances. An instance is a set of multiple VLANs. Binding multiple VLANs to one instance can reduce the communication overhead and resource utilization.

Ruijie devices support STP, RSTP, and MSTP, and comply with IEEE 802.1D, IEEE 802.1w, and IEEE 802.1s.

Protocols and Standards

- IEEE 802.1D: Media Access Control (MAC) Bridges
- IEEE 802.1w: Part 3: Media Access Control (MAC) Bridges—Amendment 2: Rapid Reconfiguration
- IEEE 802.1s: Virtual Bridged Local Area Networks—Amendment 3: Multiple Spanning Trees

6.2 Applications

Application	Description
MSTP+VRRP Dual-Core Topology	With a hierarchical network architecture model, the MSTP+VRRP mode is used to implement redundancy and load balancing to improve system availability of the network.

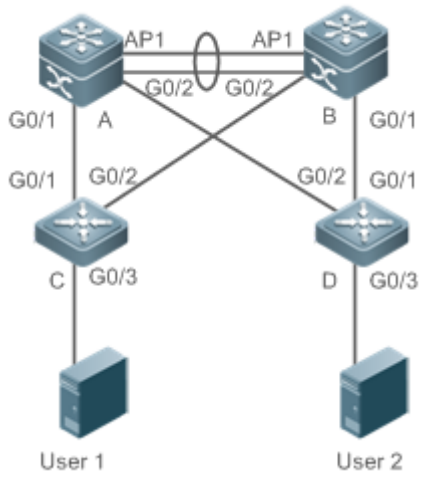
6.2.1 MSTP+VRRP Dual-Core Topology

Scenario

The typical application of MSTP is the MSTP+VRRP dual-core solution. This solution is an excellent solution to improve system availability of the network. Using a hierarchical network architecture model, it is generally divided into three layers (core layer, convergence layer, and access layer) or two layers (core layer and access layer). They form the core network system to provide data exchange service.

The main advantage of this architecture is its hierarchical structure. In the hierarchical network architecture, all capacity indicators, characteristics, and functions of network devices at each layer are optimized based on their network locations and roles, enhancing their stability and availability.

Figure 6-1 MSTP+VRRP Dual-Core Topology



Remarks	The topology is divided into two layers: core layer (Devices A and B) and access layer (Devices C and D).

Deployment

- Core layer: Multiple MSTP instances are configured to realize load balancing. For example, two instances are created: Instance 1 and Instance 2. Instance 1 maps VLAN 10 while Instance 2 maps VLAN 20. Device A is the root bridge of Instances 0 and 1 (Instance 0 is CIST, which exists by default). Device B is the root bridge of Instance 2.
- Core layer: Devices A and B are the active VRRP devices respectively on VLAN 10 and VLAN 20.
- Access layer: Configure the port directly connected to the terminal (PC or server) as a PortFast port, and enable BPDU guard to prevent unauthorized users from accessing illegal devices.

6.3 Features

Basic Concepts

BPDU

To generate a stable tree topology network, the following conditions must be met:

- Each bridge has a unique ID consisting of the bridge priority and MAC address.
- The overhead of the path from the bridge to the root bridge is called root path cost.
- A port ID consists of the port priority and port number.

Bridges exchange BPDU packets to obtain information required for establishing the best tree topology. These packets use the multicast address 01-80-C2-00-00-00 (hexadecimal) as the destination address.

A BPDU consists of the following elements:

- Root bridge ID assumed by the local bridge
- Root path cost of the local bridge
- Bridge ID (ID of the local bridge)
- Message age (age of a packet)
- Port ID (ID of the port sending this packet)
- **Forward-Delay Time**, **Hello Time**, **Max-Age Time** are time parameters specified in the MSTP.
- Other flags, such as flags indicating network topology changes and local port status.

If a bridge receives a BPDU with a higher priority (smaller bridge ID and lower root path cost) at a port, it saves the BPDU information at this port and transmits the information to all other ports. If the bridge receives a BPDU with a lower priority, it discards the information.

Such a mechanism allows information with higher priorities to be transmitted across the entire network. BPDU exchange results are as follows:

- A bridge is selected as the root bridge.
- Except the root bridge, each bridge has a root port, that is, a port providing the shortest path to the root bridge.
- Each bridge calculates the shortest path to the root bridge.

- Each LAN has a designated bridge located in the shortest path between the LAN and the root bridge. A port designated to connect the bridge and the LAN is called designated port.
- The root port and designated port enter the forwarding status.

Bridge ID

According to IEEE 802.1W, each bridge has a unique ID. The spanning tree algorithm selects the root bridge based on the bridge ID. The bridge ID consists of eight bytes, of which the last six bytes are the MAC address of the bridge. In its first two bytes (as listed in the following table), the first four bits indicate the priority; the last eight bits indicate the system ID for use in extended protocol. In RSTP, the system ID is 0. Therefore, the bridge priority should be a integral multiple of 4,096.

	Bit	Value
Priority value	16	32,768
	15	16,384
	14	8,192
	13	4,096
System ID	12	2,048
	11	1,024
	10	512
	9	256
	8	128
	7	64
	6	32
	5	16
	4	8
	3	4
	2	2
	1	1

Spanning-Tree Timers

The following three timers affect the performance of the entire spanning tree:

- Hello timer: Interval for periodically sending a BPDU packet.
- Forward-Delay timer: Interval for changing the port status, that is, interval for a port to change from the listening state to the learning state or from the learning state to the forwarding state when RSTP runs in STP-compatible mode.
- Max-Age timer: The longest time-to-live (TTL) of a BPDU packet. When this timer elapses, the packet is discarded.

Port Roles and Port States

Each port plays a role on a network to reflect different functions in the network topology.

- Root port: Port providing the shortest path to the root bridge.
- Designated port: Port used by each LAN to connect the root bridge.

- Alternate port: Alternative port of the root port. Once the root port loses effect, the alternate port immediately changes to the root port.
- Backup port: Backup port of the designated port. When a bridge has two ports connected to a LAN, the port with the higher priority is the designated port while the port with the lower priority is the backup port.
- Disabled port: Inactive port. All ports with the operation state being down play this role.

The following figures show the roles of different ports:

R = Root port D = Designated port A = Alternate port B = Backup port

Unless otherwise specified, port priorities decrease from left to right.

Figure 6-2

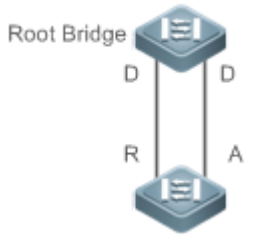


Figure 6-3

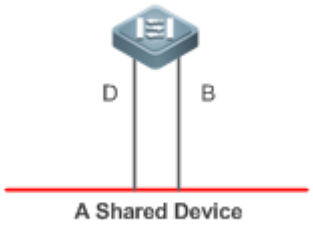

Figure 6-4

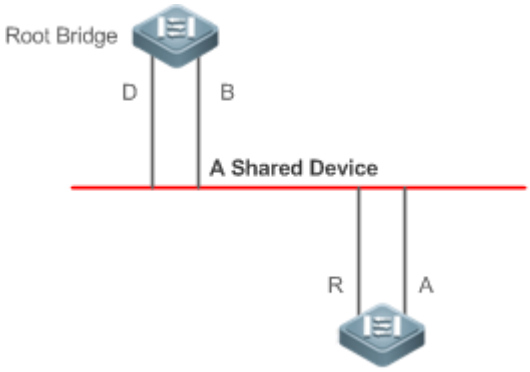


Each port has three states indicating whether to forward data packets so as to control the entire spanning tree topology.

- Discarding: Neither forwards received packets nor learns the source MAC address.
- Learning: Does not forward received packets but learns the source MAC address, which is a transitive state.

- Forwarding: Forwards received packets and learns the source MAC address.

For a stable network topology, only the root port and designated port can enter the forwarding state while other ports are always in discarding state.

Hop Count

Internal spanning trees (ISTs) and multiple spanning tree instances (MSTIs) calculate whether the BPDU packet time expires based on an IP TTL-alike mechanism Hop Count, instead of Message Age and Max Age.

It is recommended to run the **spanning-tree max-hops** command in global configuration mode to configure the hop count. In a region, every time a BPDU packet passes through a device from the root bridge, the hop count decreases by 1. When the hop count becomes 0, the BPDU packet time expires and the device discards the packet.

To be compatible with STP and RSTP outside the region, MSTP also retains the Message Age and Max Age mechanisms.

Overview

Feature	Description
STP	STP, defined by the IEEE in 802.1D, is used to eliminate physical loops at the data link layer in a LAN.
RSTP	RSTP, defined by the IEEE in 802.1w, is optimized based on STP to rapidly converge the network topology.
MSTP	MSTP, defined by the IEEE in 802.1s, resolves defects of STP, RSTP, and Per-VLAN Spanning Tree (PVST). It cannot only rapidly converge but also can forward traffic of different VLANs along respective paths, thereby providing a better load balancing mechanism for redundant links.
MSTP Optical Features	MSTP includes the following features: PortFast, BPDU guard, BPDU filter, TC protection, TC guard, TC filter, BPDU check based on the source MAC address, BPDU filter based on the illegal length, Auto Edge, root guard, and loop guard.

6.3.1 STP

STP is used to prevent broadcast storms incurred by loops and provide link redundancy.

Working Principle

For the Layer-2 Ethernet, only one active link can exist between two LANs. Otherwise, a broadcast storm will occur. To enhance the reliability of a LAN, it is necessary to establish a redundant link and keep some paths in backup state. If the network is faulty and a link fails, you must switch the redundant link to the active state. STP can automatically activate the redundant link without any manual operations. STP enables devices on a LAN to:

- Discover and start the best tree topology on the LAN.
- Troubleshoot a fault and automatically update the network topology so that the possible best tree topology is always selected.

The LAN topology is automatically calculated based on a set of bridge parameters configured by the administrator. The best topology tree can be obtained by properly configuring these parameters.

6.3.2 RSTP

RSTP is completely compatible with 802.1D STP. Similar to traditional STP, RSTP provides loop-free and redundancy services. It is characterized by rapid speed. If all bridges in a LAN support RSTP and are properly configured by the administrator, it takes less than 1 second (about 50 seconds if traditional STP is used) to re-generate a topology tree after the network topology changes.

Working Principle

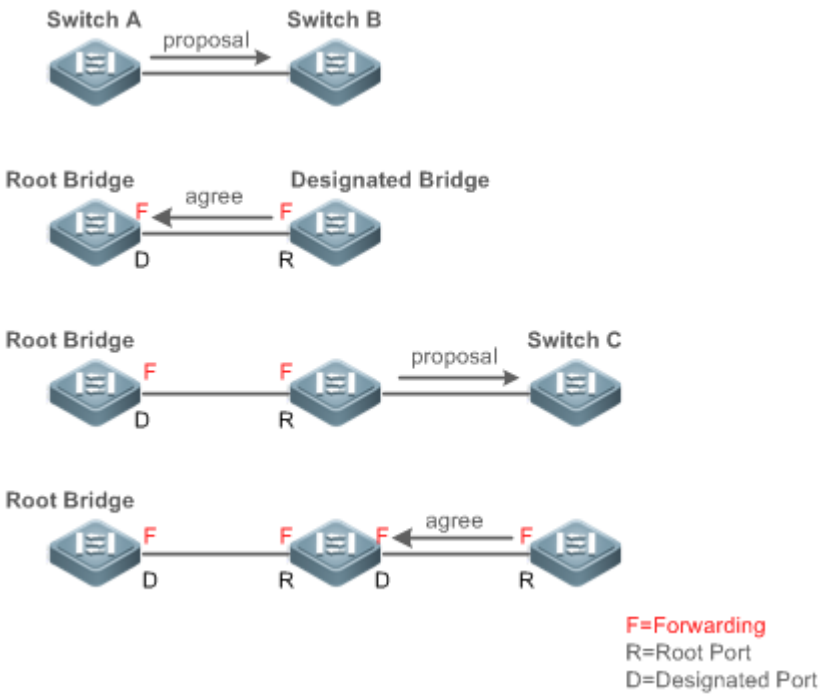
Fast RSTP Convergence

RSTP has a special feature, that is, to make ports quickly enter the forwarding state.

STP enables a port to enter the forwarding state 30 seconds (two times of the Forward-Delay Time; the Forward-Delay Time can be configured, with a default value of 15 seconds) after selecting a port role. Every time the topology changes, the root port and designated port reselected by each bridge enter the forwarding state 30 seconds later. Therefore, it takes about 50 seconds for the entire network topology to become a tree.

RSTP differs greatly from STP in the forwarding process. As shown in Figure 6-, Switch A sends an RSTP Proposal packet to Switch B. If Switch B finds the priority of Switch A higher, it selects Switch A as the root bridge and the port receiving the packet as the root port, enters the forwarding state, and then sends an Agree packet from the root port to Switch A. If the designated port of Switch A is agreed, the port enters the forwarding state. Switch B's designated port resends a Proposal packet to extend the spanning tree by sequence. Theoretically, RSTP can recover the network tree topology to rapidly converge once the network topology changes.

Figure 6-5



The above handshake process is implemented only when the connection between ports is in point-to-point mode. To give the devices their full play, it is recommended not to enable point-to-point connection between devices.

Figure 6- and Figure 6- show the examples of non point-to-point connection.

Example of non point-to-point connection:

Figure 6-6

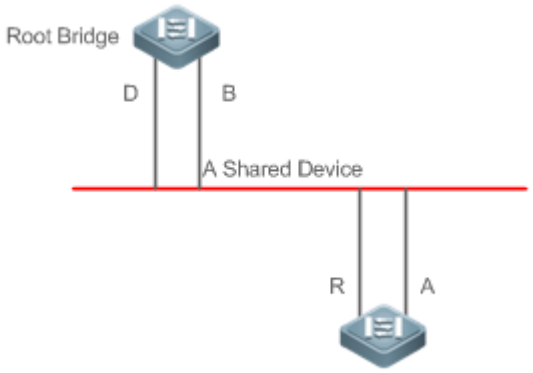


Figure 6-7

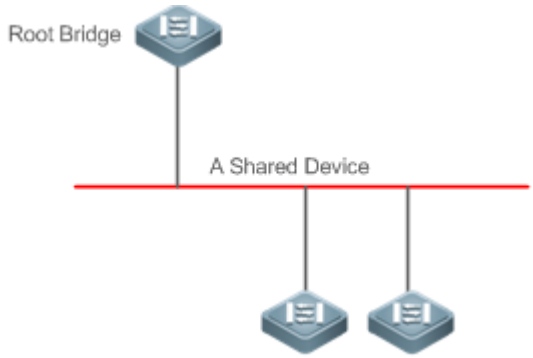

Figure 6- shows an example of point-to-point connection.

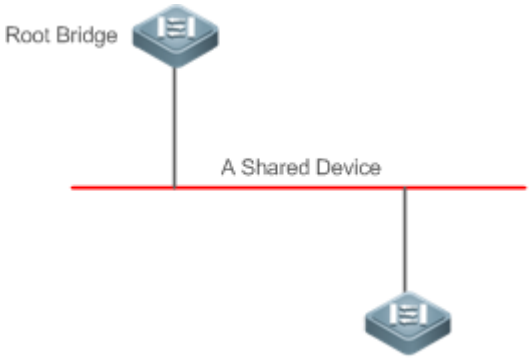
Figure 6-8



Compatibility Between RSTP and STP

RSTP is completely compatible with STP. RSTP automatically checks whether the connected bridge supports STP or RSTP based on the received BPDU version number. If the port connects to an STP bridge, the port enters the forwarding state 30 seconds later, which cannot give RSTP its full play.

Another problem may occur when RSTP and STP are used together. As shown in the following figures, Switch A (RSTP) connects to Switch B (STP). If Switch A finds itself connected to an STP bridge, it sends an STP BPDU packet. However, if Switch B is replaced with Switch C (RSTP) but Switch A still sends STP BPDU packets, Switch C will assume itself connected to the STP bridge. As a result, two RSTP devices work under STP, greatly reducing the efficiency.

RSTP provides the protocol migration feature to forcibly send RSTP BPDU packets (the peer bridge must support RSTP). In this case, Switch A is enforced to send an RSTP BPDU and Switch C then finds itself connected to the RSTP bridge. As a result, two RSTP devices work under RSTP, as shown in Figure 6-.

Figure 6-9

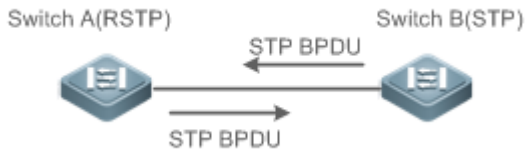


Figure 6-10

6.3.3 MSTP

MSTP resolves defects of STP and RSTP. It cannot only rapidly converge but also can forward traffic of different VLANs along respective paths, thereby providing a better load balancing mechanism for redundant links.

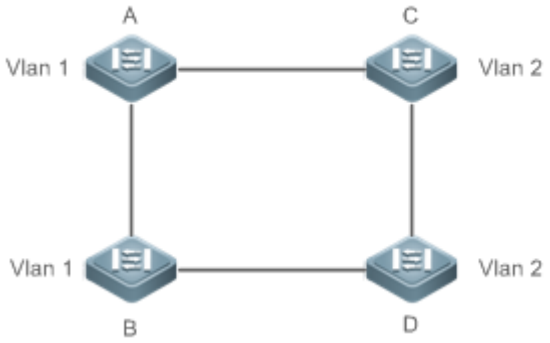
Working Principle

Ruijie devices support MSTP. MSTP is a new spanning tree protocol developed from traditional STP and RSTP and includes the fast RSTP forwarding mechanism.

Since traditional spanning tree protocols are irrelevant to VLANs, problems may occur in specific network topologies:

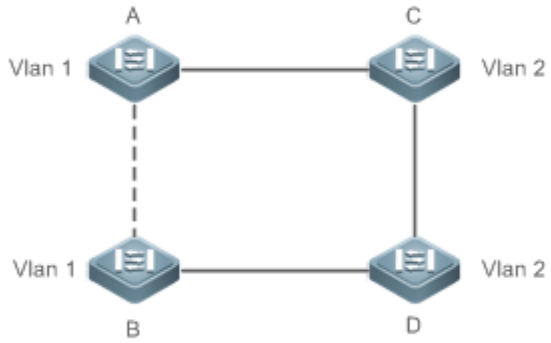
As shown in Figure 6-, Devices A and B are in VLAN 1 while Devices C and D are in VLAN 2, forming a loop.

Figure 6-11



If the link from Device A to Device B through Devices C and D costs less than the link from Device A direct to Device B, the link between Device A and Device B enters the discarding state (as shown in Figure 6-). Since Devices C and D do not include VLAN 1 and cannot forward data packets of VLAN 1, VLAN 1 of Device A fails to communicate with VLAN 1 of Device B.

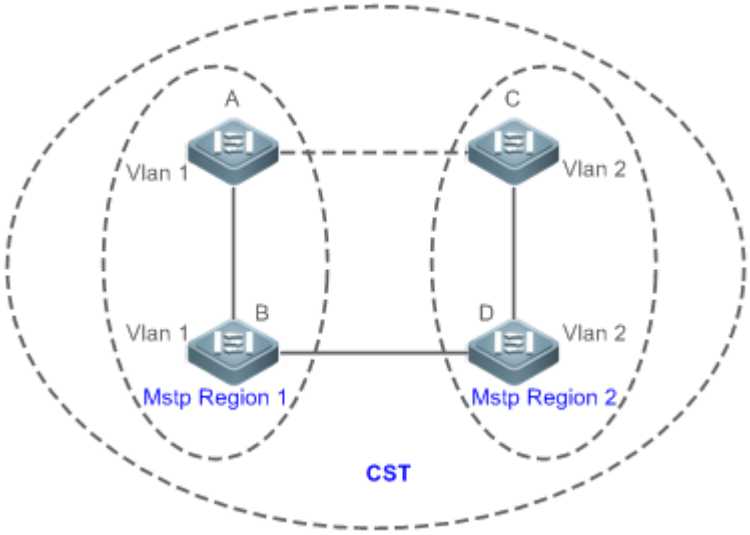
Figure 6-12



MSTP is developed to resolve this problem. It divides one or multiple VLANs of a device into an instance. Devices configured with the same instance form an MST region to run an independent spanning tree (called IST). This MST region, like a big device, implements the spanning tree algorithm with other MST regions to generate a complete spanning tree called common spanning tree (CST).

Based on this algorithm, the above network can form the topology shown in Figure 6- under the MSTP algorithm: Devices A and B are in MSTP region 1 in which no loop occurs, and therefore no link enters the discarding state. This also applies to MSTP Region 2. Region 1 and Region 2, like two big devices having loops, select a link to enter the discarding state based on related configuration.

Figure 6-13



This prevents loops to ensure proper communication between devices in the same VLAN.

MSTP Region Division

To give MSTP its due play, properly divide MSTP regions and configure the same MST configuration information for devices in the same MSTP region.

MST configuration information include:

- MST configuration name: Consists of at most 32 bytes to identify an MSTP region.
- MST Revision Number: Consists of 16 bits to identify an MSTP region.
- MST instance-VLAN mapping table: A maximum number of 64 instances (with their IDs ranging from 1 to 64) are created for each device and Instance 0 exists mandatorily. Therefore, the system supports a maximum number of 65 instances. Users can assign 1 to 4,994 VLANs belonging to different instances (ranging from 0 to 64) as required. Unassigned VLANs belong to Instance 0 by default. In this case, each MSTI is a VLAN group and implements the spanning tree algorithm of the MSTI specified in the BPDU packet, not affected by CIST and other MSTIs.

Run the **spanning-tree mst configuration** command in global configuration mode to enter the MST configuration mode to configure the above information.

MSTP BPDUs carry the above information. If the BPDU received by a device carries the same MST configuration information with the information on the device, it regards that the connected device belongs to the same MST region with itself. Otherwise, it regards the connected device originated from another MST region.

It is recommended to configure the instance-VLAN mapping table after disabling MSTP. After the configuration, re-enable MSTP to ensure stability and convergence of the network topology.

IST (Spanning Tree in an MSTP Region)

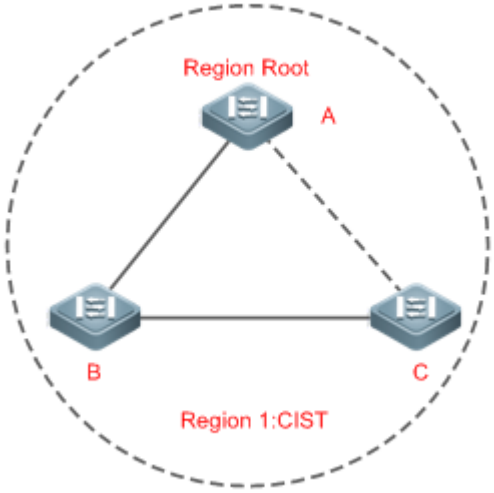
After MSTP regions are divided, each region selects an independent root bridge for each instance based on the corresponding parameters such as bridge priority and port priority, assigns roles to each port on each device, and specifies whether the port is in forwarding or discarding state in the instance based on the port role.

Through MSTP BPDU exchange, an IST is generated and each instance has their own spanning trees (MSTIs), in which the spanning tree corresponding to Instance 0 and CST are uniformly called Common Instance Spanning Tree (CIST). That is, each instance provides a single and loop-free network topology for their own VLAN groups.

As shown in Figure 6-, Devices A, B, and C form a loop in Region 1.

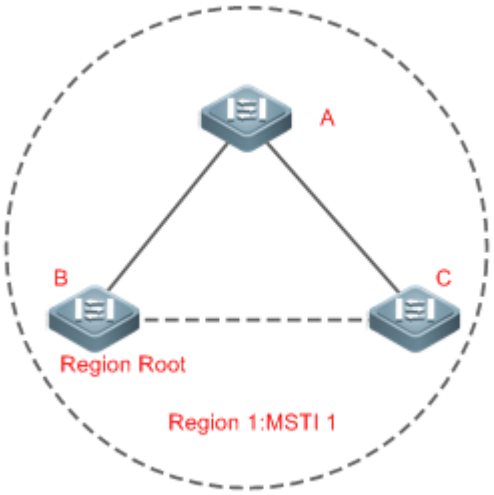
As shown in Figure 6-,, Device A has the highest priority in the CIST (Instance 0) and thereby is selected as the region root. Then MSTP enables the link between A and C to enter the discarding state based on other parameters. Therefore, for the VLAN group of Instance 0, only links from A to B and from B to C are available, interrupting the loop of this VLAN group.

Figure 6-14



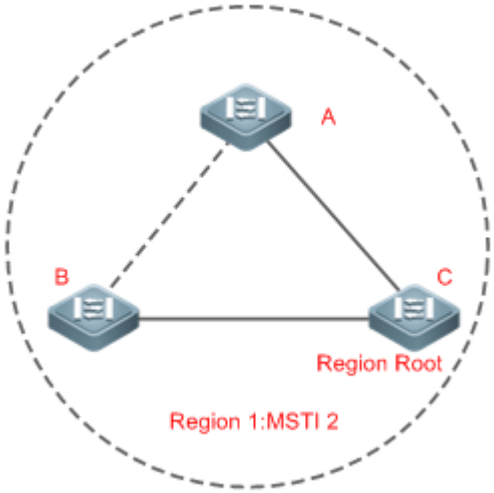
As shown in Figure 6-, Device B has the highest priority in the MSTI 1 (Instance 1) and thereby is selected as the region root. Then MSTP enables the link between B and C to enter the discarding state based on other parameters. Therefore, for the VLAN group of Instance 1, only links from A to B and from A to C are available, interrupting the loop of this VLAN group.

Figure 6-15



As shown in Figure 6-, Device C has the highest priority in the MSTI 2 (Instance 2) and thereby is selected as the region root. Then MSTP enables the link between B and C to enter the discarding state based on other parameters. Therefore, for the VLAN group of Instance 2, only links from B to C and from A to C are available, interrupting the loop of this VLAN group.

Figure 6-16

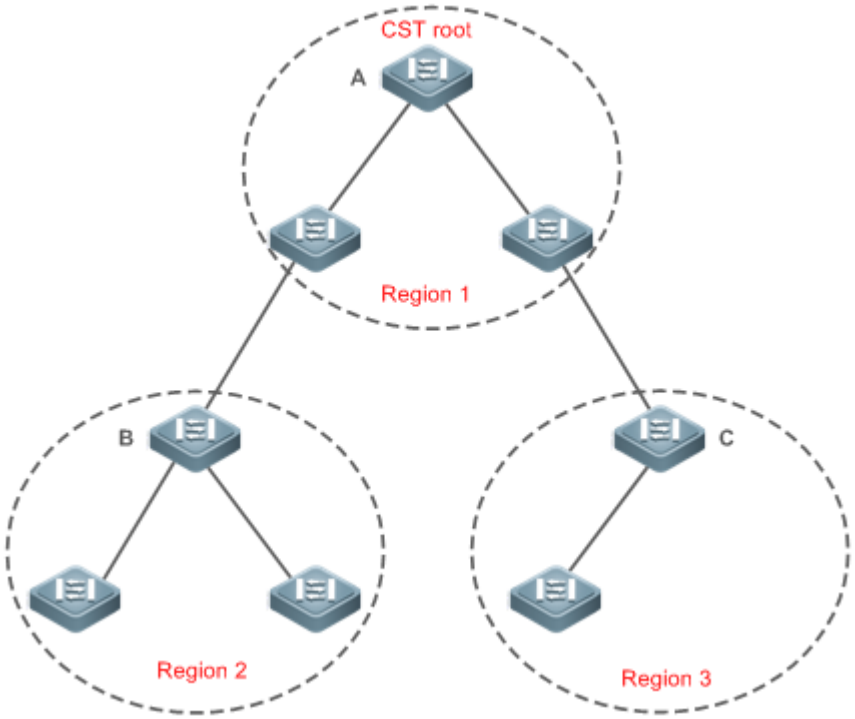


Note that MSTP does not care which VLAN a port belongs to. Therefore, users should configure the path cost and priority of a related port based on the actual VLAN configuration to prevent MSTP from interrupting wrong loops.

↘ CST (Spanning Tree Between MSTP Regions)

Each MSTP region is like a big device for the CST. Different MSTP regions form a bit network topology tree called CST. As shown in Figure 6-, Device A, of which the bridge ID is the smallest, is selected as the root in the entire CST and the CIST regional root in this region. In Region 2, since the root path cost from Device B to the CST root is lowest, Device B is selected as the CIST regional root in this region. For the same reason, Device C is selected as the CIST regional root.

Figure 6-17



The CIST regional root may not be the device of which the bridge ID is the smallest in the region but indicates the device of which the root path cost from this region to the CST root is the smallest.

For the MSTI, the root port of the CIST regional root has a new role "master port". The master port acts as the outbound port of all instances and is in forwarding state for all instances. To make the topology more stable, we suggest that the master port of each region to the CST root be on the same device of the region if possible.

Compatibility Among MSTP, RSTP, and STP

Similar to RSTP, MSTP sends STP BPDUs to be compatible with STP. For details, see "Compatibility Between RSTP and STP".

Since RSTP processes MSTP BPDUs of the CIST, MSTP does not need to send RSTP BPDUs to be compatible with it.

Each STP or RSTP device is a single region and does not form the same region with any devices.

6.3.4 MSTP Optional Features

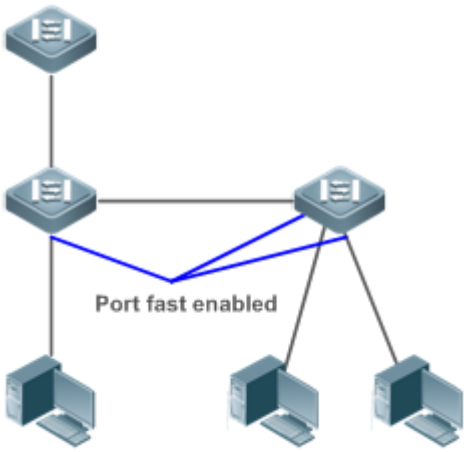
MSTP optional features mainly include PortFast port, BPDU guard, BPDU filter, TC guard, and guard. The optional features are mainly used to deploy MSTP configurations based on the network topology and application characteristics in the MSTP network. This enhances the stability, robustness, and anti-attack capability of MSTP, meeting application requirements of MSTP in different customer scenarios.

Working Principle

PortFast

If a port of a device connects directly to the network terminal, this port is configured as a PortFast port to directly enter the forwarding state. If the PortFast port is not configured, the port needs to wait for 30 seconds to enter the forwarding state. Figure 6- shows which ports of a device can be configured as PortFast ports.

Figure 6-18



If a PortFast port still receives BPDUs, its Port Fast Operational State is Disabled and the port enters the forwarding state according to the normal STP algorithm.

BPDU Guard

BPDU guard can be enabled globally or enabled on an interface.

It is recommended to run the **spanning-tree portfast bpduguard default** command in global configuration mode to enable global BPDU guard. If PortFast is enabled on a port or this port is automatically identified as an edge port, this port enters the error-disabled state to indicate the configuration error immediately after receiving a BPDU. At the same time, the port is disabled, indicating that a network device may be added by an unauthorized user to change the network topology.

It is also recommended to run the **spanning-tree bpduguard enable** command in interface configuration mode to enable BPDU guard on a port (whether PortFast is enabled or not on the port). In this case, the port enters the error-disabled state immediately after receiving a BPDU.

BPDU Filter

BPDU filter can be enabled globally or enabled on an interface.

It is recommended to run the **spanning-tree portfast bpdufilter default** command in global configuration mode to enable global BPDU filter. In this case, the PortFast port neither receives nor sends BPDUs and therefore the host connecting directly to the PortFast port receives no BPDUs. If the port changes its Port Fast Operational State to Disabled after receiving a BPDU, BPDU filter automatically loses effect.

It is also recommended to run the **spanning-tree bpdufilter enable** command in interface configuration mode to enable BPDU filter on a port (whether PortFast is enabled or not on the port). In this case, the port neither receives nor sends BPDUs but directly enters the forwarding state.

TC Protection

TC BPDUs are BPDU packets carrying the TC. If a switch receives such packets, it indicates the network topology changes and the switch will delete the MAC address table. For Layer-3 switches in this case, the forwarding module is re-enabled and the port status in the ARP entry changes. When a switch is attacked by forged TC BPDUs, it will frequently perform the above operations, causing heavy load and affecting network stability. To prevent this problem, you can enable TC protection.

TC protection can only be globally enabled or disabled. This function is disabled by default.

When TC protection is enabled, the switch deletes TC BPDUs within a specified period (generally 4 seconds) after receiving them and monitors whether any TC BPDU packet is received during the period. If a device receives TC BPDU packets during this period, it deletes them when the period expires. This can prevent the device from frequently deleting MAC address entries and ARP entries.

TC Guard

TC protection ensures less dynamic MAC addresses and ARP entries removed when a large number of TC packets are generated on the network. However, a device receiving TC attack packets still performs many removal operations and TC packets can be spread, affecting the entire network. Users can enable TC guard to prevent TC packets from spreading globally or on a port. If TC guard is enabled globally or on a port, a port receiving TC packets filters these TC packets or TC packets generated by itself so that TC packets will not be spread to other ports. This can effectively control possible TC attacks in the network to ensure network stability. Particularly on Layer-3 devices, this function can effectively prevent the access-layer device from flapping and interrupting the core route.

- If TC guard is used incorrectly, the communication between networks is interrupted.
- It is recommended to enable this function only when illegal TC attack packets are received in the network.
- If TC guard is enabled globally, no port spreads TC packets to others. This function can be enabled only on laptop access devices.
- If TC guard is enabled on a port, the topology changes incurred and TC packets received on the port will not be spread to other ports. This function can be enabled only on uplink ports, particularly on ports of the convergence core.

TC Filter

If TC guard is enabled on a port, the port does not forward TC packets received and generated by the port to other ports performing spanning tree calculation on the device. When the status of a port changes (for example, from blocking to forwarding), the port generates TC packets, indicating that the topology may have changed.

In this case, since TC guard prevents TC packets from spreading, the device may not clear the MAC addresses of the port when the network topology changes, causing a data forwarding error.

To resolve this problem, TC filter is introduced. TC filter does not process TC packets received by ports but processes TC packets in case of normal topology changes. If TC filter is enabled, the address removal problem will be avoided and the core route will not be interrupted when ports not enabled with PortFast frequently go up or down, and the core routing entries can be updated in a timely manner when the topology changes.

- TC filter is disabled by default.

BPDU Source MAC Address Check

BPDU source MAC address check prevents BPDU packets from maliciously attacking switches and causing MSTP abnormal. When the switch connected to a port on a point-to-point link is determined, you can enable BPDU source MAC address check to receive BPDU packets sent only by the peer switch and discard all other BPDU packets, thereby preventing malicious attacks. You can enable the BPDU source MAC address check in interface configuration mode for a specific port. One port can only filter one MAC address. If you run the **no bpdu src-mac-check** command to disable BPDU source MAC address check on a port, the port receives all BPDU packets.

BPDU Filter

If the Ethernet length of a BPDU exceeds 1,500, this BPDU will be discarded, preventing receipt of illegal BPDU packets.

Auto Edge

If the designated port of a device does not receive a BPDU from the downlink port within a specific period (3 seconds), the device regards a network device connected to the designated port, configures the port as an edge port, and switches the port directly into the forwarding state. The edge port will be automatically identified as a non-edge port after receiving a BPDU.

You can run the **spanning-tree autoedge disabled** command to disable Auto Edge.

This function is enabled by default.

- If Auto Edge conflicts with the manually configured PortFast, the manual configuration prevails.
- Since this function is used for rapid negotiation and forwarding between the designated port and the downlink port, STP does not support this function. If the designated port is in forwarding state, the Auto Edge configuration does not take effect on this port. It takes only when rapid negotiation is re-performed, for example, when the network cable is removed and plugged.
- If BPDU filter has been enabled on a port, the port directly enters the forwarding state and is not automatically identified as an edge port.
- This function applies only to the designated port.

Root Guard

In the network design, the root bridge and backup root bridge are usually divided into the same region. Due to incorrect configuration of maintenance personnel or malicious attacks in the network, the root bridge may receive configuration information with a higher priority and thereby switches to the backup root bridge, causing incorrect changes in the network topology. Root guard is to resolve this problem.

If root guard is enabled on a port, its roles on all instances are enforced as the designated port. Once the port receives configuration information with a higher priority, it enters the root-inconsistent (blocking) state. If the port does not receive configuration information with a higher priority within a period, it returns to its original state.

If a port enters the blocking state due to root guard, you can manually restore the port to the normal state by disabling root guard on this port or disabling spanning tree guard (running **spanning-tree guard none** in interface configuration mode).

- If root guard is used incorrectly, the network link will be interrupted.
- If root guard is enabled on a non-designated port, this port will be enforced as a designated port and enter the BKN state. This indicates that the port enters the blocking state due to root inconsistency.

If a port enters the BKN state due to receipt of configuration information with a higher priority in MST0, this port will be enforced in the BKN state in all other instances.

Root guard and loop guard cannot take effect on a port at the same time.

Loop Guard

Due to the unidirectional link failure, the root port or backup port becomes the designated port and enters the forwarding state if it does not receive BPDUs, causing a network loop. Loop guard is to prevent this problem.

If a port enabled with loop guard does not receive BPDUs, the port switches its role but stays in discarding state till it receives BPDUs and recalculates the spanning tree.

You can enable loop guard globally or on a port.

Root guard and loop guard cannot take effect on a port at the same time.

Before MSTP is restarted on a port, the port enters the blocking state in loop guard. If the port still receives no BPDU after MSTP is restarted, the port will become a designated port and enter the forwarding state. Therefore, it is recommended to identify the cause why a port enters the blocking state in loop protection and rectify the fault as soon as possible before restarting MSTP. Otherwise, the spanning tree topology will still become abnormal after MSTP is restarted.

BPDU Transparent Transmission

In IEEE 802.1Q, the destination MAC address 01-80-C2-00-00-00 of the BPDU is used as a reserved address. That is, devices compliant with IEEE 802.1Q do not forward the BPDU packets received. However, devices may need to transparently transmit BPDU packets in actual network deployment. For example, if STP is disabled on a device, the device needs to transparently transmit BPDU packets so that the spanning tree between devices is properly calculated.

BPDU transparent transmission is disabled by default.

BPDU transparent transmission takes effect only when STP is disabled. If STP is enabled on a device, the device does not transparently transmit BPDU packets.

6.4 Configuration

Configuration	Description and Command	
Enabling STP	(Mandatory) It is used to enable STP.	
	spanning-tree	Enables STP and configures basic attributes.
	spanning-tree mode	Configures the STP mode.
Configuring STP Compatibility	(Optional) It is used to be compatible with competitor devices.	
	spanning-tree compatible enable	Enables the compatibility mode of a port.

Configuration	Description and Command	
	clear spanning-tree detected-protocols	Performs mandatory version check for BPDUs.
Configuring an MSTP Region	⚠ (Optional) It is used to configure an MSTP region.	
	spanning-tree mst configuration	Enters the MST configuration mode.
Enabling Fast RSTP Convergence	⚠ (Optional) It is used to configure whether the link type of a port is point-to-point connection.	
	spanning-tree link-type	Configures the link type.
Configuring Priorities	⚠ (Optional) It is used to configure the switch priority or port priority.	
	spanning-tree priority	Configures the switch priority.
	spanning-tree port-priority	Configures the port priority.
Configuring the Port Path Cost	⚠ (Optional) It is used to configure the path cost of a port or the default path cost calculation method.	
	spanning-tree cost	Configures the port path cost.
	spanning-tree pathcost method	Configures the default path cost calculation method.
Configuring the Maximum Hop Count of a BPDU Packet	⚠ (Optional) It is used to configure the maximum hop count of a BPDU packet.	
	spanning-tree max-hops	Configures the maximum hop count of a BPDU packet.
Enabling PortFast-related Features	⚠ (Optional) It is used to enable PortFast-related features.	
	spanning-tree portfast	Enables PortFast.
	spanning-tree portfast bpduguard default	Enables BPDU guard on all ports.
	spanning-tree bpduguard enabled	Enables BPDU guard on a port.
	spanning-tree portfast bpdufilter default	Enables BPDU filter on all ports.
	spanning-tree bpdufilter enabled	Enables BPDU filter on a port.
Enabling TC-related Features	⚠ (Optional) It is used to enable TC-related features.	
	spanning-tree tc-protection	Enables TC protection.
	spanning-tree tc-protection tc-guard	Enables TC guard on all ports.
	spanning-tree tc-guard	Enables TC guard on a port.
	spanning-tree ignore tc	Enables TC filter on a port.
Enabling BPDU Source MAC Address Check	⚠ (Optional) It is used to enable BPDU source MAC address check.	
	bpdu src-mac-check	Enables BPDU source MAC address check on a port.

Configuration	Description and Command	
Configuring Auto Edge	(Optional) It is used to configure Auto Edge.	
	spanning-tree autoedge	Enables Auto Edge on a port. This function is enabled by default.
Enabling Guard-related Features	(Optional) It is used to enable port guard features.	
	spanning-tree guard root	Enables root guard on a port.
	spanning-tree loopguard default	Enables loop guard on all ports.
	spanning-tree guard loop	Enables loop guard on a port.
	spanning-tree guard none	Disables the guard feature on a port.
Enabling BPDU Transparent Transmission	(Optional) It is used to enable BPDU transparent transmission	
	bridge-frame forwarding protocol bpdu	Enables BPDU transparent transmission.

6.4.1 Enabling STP

Configuration Effect

- Enable STP globally and configure the basic attributes.
- Configure the STP mode.

Notes

- STP is disabled by default. Once STP is enabled, the device starts to run STP. The device runs MSTP by default.
- The default STP mode is MSTP mode.
- STP and Transparent Interconnection of Lots of Links (TRILL) of the data center cannot be enabled at the same time.

Configuration Steps

Enabling STP

- Mandatory.
- Unless otherwise specified, enable STP on each device.
- Run the spanning-tree [forward-time seconds | hello-time seconds | max-age seconds] command to enable STP and configure basic attributes.
- The forward-time ranges from 4 to 30. The hello-time ranges from 1 to 10. The max-age ranges from 6 to 40.
- Running the clear commands may lose vital information and thus interrupt services. The value ranges of forward-time, hello-time, and max-age are related. If one of them is modified, the other two ranges are affected. The three values must meet the following condition: 2 x (Hello Time + 1 second) <= Max-Age Time <= 2 x (Forward-Delay Time –1 second). Otherwise, the topology may become unstable.

Command	**spanning-tree** [**forward-time** *seconds* | **hello-time** *seconds* | **max-age** *seconds* | **tx-hold-count** *numbers*]

Parameter Description	**forward-time** *seconds*: Indicates the interval when the port status changes. The value ranges from 4 to 30 seconds. The default value is 15 seconds. **hello-time** *seconds*: Indicates the interval when a device sends a BPDU packet. The value ranges from 1 to 10 seconds. The default value is 2 seconds. **max-age** *second*: Indicates the longest TTL of a BPDU packet. The value ranges from 6 to 40 seconds. The default value is 20 seconds. **tx-hold-count** *numbers*: Indicates the maximum number of BPDUs sent per second. The value ranges from 1 to 10. The default value is 3.
Defaults	STP is disabled by default.
Command Mode	Global configuration mode
Usage Guide	The value ranges of forward-time, hello-time, and max-age are related. If one of them is modified, the other two ranges are affected. The three values must meet the following condition: 2 x (Hello Time + 1 second) <= Max-Age Time <= 2 x (Forward-Delay Time – 1 second) Otherwise, the topology may become unstable.

Configuring the STP Mode

- Optional.
- According to related 802.1 protocol standards, STP, RSTP, and MSTP are mutually compatible, without any configuration by the administrator. However, some vendors' devices do not work according to 802.1 protocol standards, possibly causing incompatibility. Therefore, Ruijie provides a command for the administrator to switch the STP mode to a lower version if other vendors' devices are incompatible with Ruijie devices.
- Run the **spanning-tree mode** [**stp | rstp | mstp**] command to modify the STP mode.

Command	**spanning-tree mode** [**stp** | **rstp** | **mstp**]
Parameter Description	**stp**: Spanning Tree Protocol (IEEE 802.1d) **rstp**: Rapid Spanning Tree Protocol (IEEE 802.1w) **mstp**: Multiple Spanning Tree Protocol (IEEE 802.1s)
Defaults	The default value is **mstp**.
Command Mode	Global configuration mode
Usage Guide	However, some vendors' devices do not work according to 802.1 protocol standards, possibly causing incompatibility. If other vendors' devices are incompatible with Ruijie devices, run this command to switch the STP mode to a lower version.

Verification

- Display the configuration.

Configuration Example

Enabling STP and Configuring Timer Parameters

Scenario **Figure 6-19**	
Configuration Steps	● Enable STP and set the STP mode to STP on the devices. ● Configure the timer parameters of root bridge DEV A as follows: Hello Time=4s, Max Age=25s, Forward Delay=18s.
DEV A	Step 1: Enable STP and set the STP mode to STP. `Ruijie#configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.` `Ruijie(config)#spanning-tree` `Ruijie(config)#spanning-tree mode stp` Step 2: Configure the timer parameters of root bridge DEV A. `Ruijie(config)#spanning-tree hello-time 4` `Ruijie(config)#spanning-tree max-age 25` `Ruijie(config)#spanning-tree forward-time 18`
DEV B	Enable STP and set the STP mode to STP. `Ruijie#configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.` `Ruijie(config)#spanning-tree` `Ruijie(config)#spanning-tree mode stp`
Verification	● Run the **show spanning-tree summary** command to display the spanning tree topology and protocol configuration parameters.
DEV A	`Ruijie#show spanning-tree summary` `Spanning tree enabled protocol stp` `  Root ID    Priority    0`

	Address 00d0.f822.3344 this bridge is root Hello Time 4 sec Forward Delay 18 sec Max Age 25 sec Bridge ID Priority 0 Address 00d0.f822.3344 Hello Time 4 sec Forward Delay 18 sec Max Age 25 sec Interface Role Sts Cost Prio OperEdge Type ---------- ---- --- ---------- -------- -------- ---------- Gi0/2 Desg FWD 20000 128 False P2p Gi0/1 Desg FWD 20000 128 False P2p
DEV B	Ruijie#show spanning-tree summary Spanning tree enabled protocol stp Root ID Priority 0 Address 00d0.f822.3344 this bridge is root Hello Time 4 sec Forward Delay 18 sec Max Age 25 sec Bridge ID Priority 32768 Address 001a.a917.78cc Hello Time 2 sec Forward Delay 15 sec Max Age 20 sec Interface Role Sts Cost Prio OperEdge Type ---------- ---- --- ---------- -------- -------- ---------- Gi0/2 Altn BLK 20000 128 False P2p Bound(STP) Gi0/1 Root FWD 20000 128 False P2p Bound(STP)

Common Errors

The timer parameters will take effect only after the device has been elected as a root bridge.

6.4.2 Configuring STP Compatibility

Configuration Effect

- Enable the compatibility mode of a port to realize interconnection between Ruijie devices and other SPs' devices.
- Enable protocol migration to perform forcible version check to affect the compatibility between RSTP and STP.

Notes

- If the compatibility mode is enabled on a port, this port will add different MSTI information into the to-be-sent BPDU based on the current port to realize interconnection between Ruijie devices and other SPs' devices.

Configuration Steps

Enabling the Compatibility Mode on a Port

- Optional.

Command	**spanning-tree compatible enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	If the compatibility mode is enabled on a port, this port will add different MSTI information into the to-be-sent BPDU based on the current port to realize interconnection between Ruijie devices and other SPs' devices.

Enabling Protocol Migration

- Optional.
- If the peer device supports RSTP, you can enforce version check on the local device to force the two devices to run RSTP.

Command	**clear spanning-tree detected-protocols** [**interface** *interface-id*]
Parameter Description	**interface** *interface-id*: Indicates a port.
Command Mode	Privileged EXEC mode
Usage Guide	This command is used to enforce a port to send RSTP BPDU packets and perform forcible check on them.

Verification

- Display the configuration.

Configuration Example

Enabling STP Compatibility

Scenario **Figure 6-20**	
Configuration Steps	● Configure Instances 1 and 2 on Devices A and B, and map Instance 1 with VLAN 10 and Instance 2 with VLAN 20. ● Configure Gi0/1 and Gi0/2 to respectively belong to VLAN 10 and VLAN 20, and enable STP compatibility.
DEV A	Step 1: Configure Instances 1 and 2, and map Instances 1 and 2 respectively with VLANs 10 and 20. `Ruijie#configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.` `Ruijie(config)#spanning-tree mst configuration` `Ruijie(config-mst)#instance 1 vlan 10` `Ruijie(config-mst)#instance 2 vlan 20` Step 2: Configure the VLAN the port belongs to, and enable STP compatibility on the port. `Ruijie(config)#int gi 0/1` `Ruijie(config-if-GigabitEthernet 0/1)#switchport access vlan 10` `Ruijie(config-if-GigabitEthernet 0/1)#spanning-tree compatible enable` `Ruijie(config-if-GigabitEthernet 0/1)#int gi 0/2` `Ruijie(config-if-GigabitEthernet 0/2)#switchport access vlan 20` `Ruijie(config-if-GigabitEthernet 0/2)#spanning-tree compatible enable`
DEV B	Perform the same steps as DEV A.
Verification	● Run the **show spanning-tree summary** command to check whether the spanning tree topology is correctly calculated.
DEV A	`Ruijie#show spanning-tree summary` `Spanning tree enabled protocol mstp`

```

Common Errors

It is recommended to configure a same VLAN list on the two sides of the link.

6.4.3 Configuring an MSTP Region

Configuration Effect

- Configure an MSTP region to adjust which devices belong to the same MSTP region and thereby affect the network topology.

Notes

- To make multiple devices belong to the same MSTP region, configure the same name, revision number, and instance-VLAN mapping table for them.
- You can configure VLANs for Instances 0 to 64, and then the remaining VLANs are automatically allocated to Instance 0. One VLAN belongs to only one instance.
- It is recommended to configure the instance-VLAN mapping table after disabling STP. After the configuration, re-enable MSTP to ensure stability and convergence of the network topology.

Configuration Steps

Configuring an MSTP Region

- Optional.
- Configure an MSTP region when multiple devices need to belong to the same MSTP region.

Command	**spanning-tree mst configuration**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Run this command to enter the MST configuration mode.

Configuring the Relationship between MST Instance and Vlan

Command	**instance** *instance-id* **vlan** *vlan-range*
Parameter Description	*instance-id*: Indicates the MSTI ID, ranging from 0 to 64. *vlan-range*: Indicates the VLAN ID, ranging from 1 to 4,094.
Command Mode	MST configuration mode
Usage Guide	To add a VLAN group to an MSTI, run this command. For example, instance 1 vlan 2-200: Adds VLANs 2 to 200 to Instance 1. instance 1 vlan 2,20,200: Adds VLANs 2, 20, and 200 to Instance 1. You can use the **no** form of this command to remove VLANs from an instance. Removed VLANs are automatically forwarded to Instance 0.

Configuring MST Name

Command	**name** *name*
Parameter Description	*name*: Indicates the MST name. It consists of a maximum of 32 bytes.
Command Mode	MST configuration mode
Usage Guide	N/A

Configuring MST Version

Command	**revision** *version*
Parameter Description	*version*: Indicates the MST revision number, ranging from 0 to 65,535.
Command Mode	MST configuration mode
Usage Guide	N/A

Verification

- Display the configuration.

Configuration Example

Enabling MSTP to Achieve VLAN Load Balancing in the MSTP+VRRP Topology

Scenario **Figure 6-21**	Configuration Steps	• Enable MSTP and create Instances 1 and 2 on Switches A, B, C, and D. • Configure Switch A as the root bridge of Instances 0 and 1 and Switch B as the root bridge of Instance 2. • Configure Switch A as the VRRP master device of VLANs 1 and 10 and Switch B as the VRRP master device of VLAN 20.
A	Step 1: Configure VLANs 10 and 20, and configure ports as Trunk ports. `A(config)#vlan 10` `A(config-vlan)#vlan 20` `A(config-vlan)#exit` `A(config)#int range gi 0/1-2` `A(config-if-range)#switchport mode trunk` `A(config-if-range)#int ag 1` `A(config-if-AggregatePort 1)# switchport mode trunk` Step 2: Enable MSTP and create Instances 1 and 2. `A(config)#spanning-tree` `A(config)# spanning-tree mst configuration` `A(config-mst)#instance 1 vlan 10`

```
A(config-mst)#instance 2 vlan 20
A(config-mst)#exit
```

Step 3: Configure Switch A as the root bridge of Instances 0 and 1.

```
A(config)#spanning-tree mst 0 priority 4096
A(config)#spanning-tree mst 1 priority 4096
A(config)#spanning-tree mst 2 priority 8192
```

Step 4: Configure VRRP priorities to enable Switch A to act as the VRRP master device of VLAN 10, and configure the virtual gateway IP address of VRRP.

```
A(config)#interface vlan 10
A(config-if-VLAN 10)ip address 192.168.10.2 255.255.255.0
A(config-if-VLAN 10) vrrp 1 priority 120
A(config-if-VLAN 10) vrrp 1 ip 192.168.10.1
```

Step 5 Set the VRRP priority to the default value 100 to enable Switch A to act as the VRRP backup device of VLAN 20.

```
A(config)#interface vlan 20
A(config-if-VLAN 20)ip address 192.168.20.2 255.255.255.0
A(config-if-VLAN 20) vrrp 1 ip 192.168.20.1
```

B

Step 1: Configure VLANs 10 and 20, and configure ports as Trunk ports.

```
B(config)#vlan 10
B(config-vlan)#vlan 20
B(config-vlan)#exit
B(config)#int range gi 0/1-2
B(config-if-range)#switchport mode trunk
B(config-if-range)#int ag 1
B(config-if-AggregatePort 1)# switchport mode trunk
```

Step 2: Enable MSTP and create Instances 1 and 2.

```
B(config)#spanning-tree
B(config)# spanning-tree mst configuration
```

	B(config-mst)#instance 1 vlan 10 B(config-mst)#instance 2 vlan 20 B(config-mst)#exit Step 3: Configure Switch A as the root bridge of Instance 2. B(config)#spanning-tree mst 0 priority 8192 B(config)#spanning-tree mst 1 priority 8192 B(config)#spanning-tree mst 2 priority 4096 Step 4: Configure the virtual gateway IP address of VRRP. B(config)#interface vlan 10 B(config-if-VLAN 10)ip address 192.168.10.3 255.255.255.0 B(config-if-VLAN 10) vrrp 1 ip 192.168.10.1 Step 5 Set the VRRP priority to 120 to enable Switch B to act as the VRRP backup device of VLAN 20. B(config)#interface vlan 20 B(config-if-VLAN 20)vrrp 1 priority 120 B(config-if-VLAN 20)ip address 192.168.20.3 255.255.255.0 B(config-if-VLAN 20) vrrp 1 ip 192.168.20.1
C	Step 1: Configure VLANs 10 and 20, and configure ports as Trunk ports. C(config)#vlan 10 C(config-vlan)#vlan 20 C(config-vlan)#exit C(config)#int range gi 0/1-2 C(config-if-range)#switchport mode trunk Step 2: Enable MSTP and create Instances 1 and 2. C(config)#spanning-tree C(config)# spanning-tree mst configuration C(config-mst)#instance 1 vlan 10 C(config-mst)#instance 2 vlan 20 C(config-mst)#exit

	Step 3: Configure the port connecting Device C directly to users as a PortFast port and enable BPDU guard. C(config)#int gi 0/3 C(config-if-GigabitEthernet 0/3)#spanning-tree portfast C(config-if-GigabitEthernet 0/3)#spanning-tree bpduguard enable
D	Perform the same steps as Device C.
Verification	● Run the **show spanning-tree summary** command to check whether the spanning tree topology is correctly calculated. ● Run the **show vrrp brief** command to check whether the VRRP master/backup devices are successfully created.

Common Errors

- MST region configurations are inconsistent in the MSTP topology.
- VLANs are not created before you configure the mapping between the instance and VLAN.
- A device runs STP or RSTP in the MSTP+VRRP topology, but calculates the spanning tree according to the algorithms of different MST regions.

6.4.4 Enabling Fast RSTP Convergence

Configuration Effect

- Configure the link type to make RSTP rapidly converge.

Notes

- If the link type of a port is point-to-point connection, RSTP can rapidly converge. For details, see "Fast RSTP Convergence". If the link type is not configured, the device automatically sets the link type based on the duplex mode of the port. If a port is in full duplex mode, the device sets the link type to point-to-point. If a port is in half duplex mode, the device sets the link type to shared. You can also forcibly configure the link type to determine whether the port connection is point-to-point connection.

Configuration Steps

Configuring the Link Type

- Optional.

Command	**spanning-tree link-type** [**point-to-point** | **shared**]
Parameter Description	**point-to-point**: Forcibly configures the link type of a port to be point-to-point. **shared**: Forcibly configures the link type of a port to be shared.
Command Mode	Interface configuration mode
Usage Guide	If the link type of a port is point-to-point connection, RSTP can rapidly converge. If the link type is not configured, the device automatically sets the link type based on the duplex mode of the port.

Verification

- Display the configuration.
- Run the **show spanning-tree** [**mst** *instance-id*] **interface** *interface-id* command to display the spanning tree configuration of the port.

Configuration Example

Enabling Fast RSTP Convergence

Configuration Steps	Set the link type of a port to point-to-point.
	`Ruijie(config)#int gi 0/1` `Ruijie(config-if-GigabitEthernet 0/1)#spanning-tree link-type point-to-point`
Verification	- Run the **show spanning-tree summary** command to display the link type of the port.
	`Ruijie#show spanning-tree summary` `Spanning tree enabled protocol mstp` `MST 0 vlans map : ALL` `  Root ID    Priority    32768` `            Address     001a.a917.78cc`

```
            this bridge is root
            Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

  Bridge ID  Priority    32768
             Address     00d0.f822.3344
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

Interface        Role Sts Cost       Prio     OperEdge Type
---------------- ---- --- ---------- -------- -------- ----------------
Gi0/1            Root FWD 20000      128      False    P2p
```

Common Errors

If a port is in half duplex mode, the device sets the link type to shared.

6.4.5 Configuring Priorities

Configuration Effect

- Configure the switch priority to determine a device as the root of the entire network and to determine the topology of the entire network.
- Configure the port priority to determine which port enters the forwarding state.

Notes

- It is recommended to set the priority of the core device higher (to a smaller value) to ensure stability of the entire network. You can assign different switch priorities to different instances so that each instance runs an independent STP based on the assigned priorities. Devices in different regions use the priority only of the CIST (Instance 0). As described in bridge ID, the switch priority has 16 optional values: 0, 4,096, 8,192, 12,288, 16,384, 20,480, 24,576, 28,672, 32,768, 36,864, 40,960, 45,056, 49,152, 53,248, 57,344, 61,440. They are integral multiples of 4,096. The default value is 32,768.
- If two ports are connected to a shared device, the device selects a port with a higher priority (smaller value) to enter the forwarding state and a port with a lower priority (larger value) to enter the discarding state. If the two ports have the same priority, the device selects the port with a smaller port ID to enter the forwarding state. You can assign different port priorities to different instances on a port so that each instance runs an independent STP based on the assigned priorities.
- Similar to the switch priority, the port priority also has 16 optional values: 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, 240. They are integral multiples of 16. The default value is 128.

Configuration Steps

Configuring the Switch Priority

- Optional.
- To change the root or topology of a network, configure the switch priority.

Command	**spanning-tree** [**mst** *instance-id*] **priority** *priority*
Parameter Description	**mst** *instance-id*: Indicates the instance ID, ranging from 0 to 64. **priority** *priority*: Indicates the switch priority. There are 16 optional values: 0, 4,096, 8,192, 12,288, 16,384, 20,480, 24,576, 28,672, 32,768, 36,864, 40,960, 45,056, 49,152, 53,248, 57,344, 61,440. They are integral multiples of 4,096.
Command Mode	Global configuration mode
Usage Guide	Configure the switch priority to determine a device as the root of the entire network and to determine the topology of the entire network.

Configuring the Port Priority

- Optional.
- To change the preferred port entering the forwarding state, configure the port priority.

Command	spanning-tree [**mst** *instance-id*] **port-priority** *priority*
Parameter Description	**mst** *instance-id*: Indicates the instance ID, ranging from 0 to 64. **port-priority** *priority*: Indicates the port priority. There are 16 optional values: 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, 240. They are integral multiples of 4,096.
Command Mode	Interface configuration mode
Usage Guide	If a loop occurs in a region, the port with a higher priority is preferred to enter the forwarding state. If two ports have the same priority, the port with a smaller port ID is selected to enter the forwarding state. Run this command to determine which port in the loop of a region enters the forwarding state.

Verification

- Display the configuration.
- Run the **show spanning-tree** [**mst** *instance-id*] **interface** *interface-id* command to display the spanning tree configuration of the port.

Configuration Example

Configuring the Port Priority

Scenario **Figure 6-22**	
Configuration Steps	● Configure the bridge priority so that DEV A becomes the root bridge of the spanning tree. ● Configure the priority of Gi0/2 on DEV A is 16 so that Gi0/2 on DEV B can be selected as the root port.
DEV A	Step 1: Enable STP and configure the bridge priority. `Ruijie(config)#spanning-tree` `Ruijie(config)#spanning-tree mst 0 priority 0` Step 2: Configure the priority of Gi 0/2. `Ruijie(config)# int gi 0/2` `Ruijie(config-if-GigabitEthernet 0/2)#spanning-tree mst 0 port-priority 16`
DEV B	`Ruijie(config)#spanning-tree`
Verification	● Run the **show spanning-tree summary** command to display the topology calculation result of the spanning tree.
DEV A	`Ruijie# Ruijie#show spanning-tree summary` `Spanning tree enabled protocol mstp` `MST 0 vlans map : ALL` `  Root ID    Priority    0` `             Address     00d0.f822.3344` `             this bridge is root` `             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec` `  Bridge ID  Priority    0` `             Address     00d0.f822.3344` `             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec`

	Interface Role Sts Cost Prio OperEdge Type ---------- ---- --- ---------- -------- -------- ---------- Gi0/2 Desg FWD 20000 16 False P2p Gi0/1 Desg FWD 20000 128 False P2p
DEV B	Ruijie#show spanning-tree summary Spanning tree enabled protocol mstp MST 0 vlans map : ALL Root ID Priority 0 Address 00d0.f822.3344 this bridge is root Hello Time 2 sec Forward Delay 15 sec Max Age 20 sec Bridge ID Priority 32768 Address 001a.a917.78cc Hello Time 2 sec Forward Delay 15 sec Max Age 20 sec Interface Role Sts Cost Prio OperEdge Type ---------- ---- --- ---------- -------- -------- ---------- Gi0/2 Root FWD 20000 128 False P2p Gi0/1 Altn BLK 20000 128 False P2p

Common Errors

The port priority will take effect only after the designated port has been changed.

6.4.6 Configuring the Port Path Cost

Configuration Effect

- Configure the path cost of a port to determine the forwarding state of the port and the topology of the entire network.
- If the path cost of a port uses its default value, configure the path cost calculation method to affect the calculation result.

Notes

- A device selects a port as the root port if the path cost from this port to the root bridge is the lowest. Therefore, the port path cost determines the root port of the local device. The default port path cost is automatically calculated based on the port rate (Media Speed). A port with a higher rate will have a low path cost. Since this method can calculate the most scientific path cost, do not change the path cost unless required. You can assign different path costs to different instances on a port so that each instance runs an independent STP based on the assigned path costs.
- If the port path cost uses the default value, the device automatically calculates the port path cost based on the port rate. However, IEEE 802.1d-1998 and IEEE 802.1t define different path costs for the same link rate. The value is a short integer ranging from 1 to 65,535 in 802.1d-1998 while is a long integer ranging from 1 to 200,000,000 in IEEE 802.1t. The path cost of an aggregate port (AP) has two solutions: 1. Ruijie solution: Port Path Cost x 95%; 2. Solution recommended in standards: 20,000,000,000/Actual link bandwidth of the AP, in which Actual link bandwidth of the AP = Bandwidth of a member port x Number of active member ports. The administrator must unify the path cost calculation method in the entire network. The default standard is the private long integer standard.
- The following table lists path costs automatically configured for different link rate in two solutions.

Port Rate	Port	IEEE 802.1d (short)	IEEE 802.1t (long)	IEEE 802.1t (long standard)
10M	Common port	100	2000000	2000000
	AP	95	1900000	2000000÷linkupcnt
100M	Common port	19	200000	200000
	AP	18	190000	200000÷linkupcnt
1000M	Common port	4	20000	20000
	AP	3	19000	20000÷linkupcnt
10000M	Common port	2	2000	2000
	AP	1	1900	20000÷linkupcnt

- Ruijie's long integer standard is used by default. After the solution is changed to the path cost solution recommended by the standards, the path cost of an AP changes with the number of member ports in UP state. If the port path cost changes, the network topology also will change.
- If an AP is static, linkupcnt in the table is the number of active member ports. If an AP is an LACP AP, linkupcnt in the table is the number of member ports forwarding AP data. If no member port in the AP goes up, linkupcnt is 1. For details about AP and LACP, see the *Configuring AP*.

Configuration Steps

Configuring the Port Path Cost

- Optional.
- To determine which port or path data packets prefer to pass through, configure the port path cost.

Command	**spanning-tree** [**mst** *instance-id*] **cost** *cost*
Parameter Description	**mst** *instance-id*: Indicates the instance ID, ranging from 0 to 64. **cost** *cost*: Indicates the path cost, ranging from 1 to 200,000,000.

Command Mode	Interface configuration mode
Usage Guide	A larger value of *cost* indicates a higher path cost.

Configuring the Default Path Cost Calculation Method

- Optional.
- To change the path cost calculation method, configure the default path cost calculation method.

Command	**spanning-tree pathcost method** { *long* [*standard*] | *short* }
Parameter Description	*long*: Uses the path cost specified in 802.1t. *standard*: Uses the cost calculated according to the standard. *short*: Uses the path cost specified in 802.1d.
Command Mode	Global configuration mode
Usage Guide	If the port path cost uses the default value, the device automatically calculates the port path cost based on the port rate.

Verification

- Display the configuration.
- Run the **show spanning-tree** [**mst** *instance-id*] **interface** *interface-id* command to display the spanning tree configuration of the port.

Configuration Example

Configuring the Port Path Cost

Scenario Figure 6-23	
Configuration Steps	● Configure the bridge priority so that DEV A becomes the root bridge of the spanning tree. ● Configure the path cost of Gi 0/2 on DEV B is 1 so that Gi 0/2 can be selected as the root port.
DEV A	`Ruijie(config)#spanning-tree` `Ruijie(config)#spanning-tree mst 0 priority 0`

DEV B	Ruijie(config)#spanning-tree Ruijie(config)# int gi 0/2 Ruijie(config-if-GigabitEthernet 0/2)# spanning-tree cost 1
Verification	● Run the **show spanning-tree summary** command to display the topology calculation result of the spanning tree.
DEV A	Ruijie# Ruijie#show spanning-tree summary Spanning tree enabled protocol mstp MST 0 vlans map : ALL Root ID Priority 0 Address 00d0.f822.3344 this bridge is root Hello Time 2 sec Forward Delay 15 sec Max Age 20 sec Bridge ID Priority 0 Address 00d0.f822.3344 Hello Time 2 sec Forward Delay 15 sec Max Age 20 sec Interface Role Sts Cost Prio OperEdge Type ---------- ---- --- ---------- -------- -------- ---------- Gi0/2 Desg FWD 20000 128 False P2p Gi0/1 Desg FWD 20000 128 False P2p
DEV B	Ruijie#show spanning-tree summary Spanning tree enabled protocol mstp MST 0 vlans map : ALL Root ID Priority 0 Address 00d0.f822.3344 this bridge is root Hello Time 2 sec Forward Delay 15 sec Max Age 20 sec

```
  Bridge ID  Priority    32768
             Address     001a.a917.78cc
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

Interface        Role Sts Cost       Prio     OperEdge Type
---------------- ---- --- ---------- -------- -------- ----------------
Gi0/2            Root FWD 1          128      False    P2p
Gi0/1            Altn BLK 20000      128      False    P2p
```

Common Errors

The changed port path cost will take effect only on the Rx port.

6.4.7 Configuring the Maximum Hop Count of a BPDU Packet

Configuration Effect

- Configure the maximum hop count of a BPDU packet to change the BPDU TTL and thereby affect the network topology.

Notes

- The default maximum hop count of a BPDU packet is 20. Generally, it is not recommended to change the default value.

Configuration Steps

↘ Configuring the Maximum Hop Count

- (Optional) If the network topology is so large that a BPDU packet exceeds the default 20 hops, it is recommended to change the maximum hop count.

Command	**spanning-tree max-hops** *hop-count*
Parameter Description	*hop-count*: Indicates the number of devices a BPDU passes through before being discarded. It ranges from 1 to 40.
Command Mode	Global configuration mode
Usage Guide	In a region, the BPDU sent by the root bridge includes a hop count. Every time a BPDU passes through a device from the root bridge, the hop count decreases by 1. When the hop count becomes 0, the BPDU times out and the device discards the packet. This command specifies the number of devices a BPDU passes through in a region before being discarded. Changing the maximum hop count will affect all instances.

Verification

- Display the configuration.

Configuration Example

Configuring the Maximum Hop Count of a BPDU Packet

Configuration Steps	● Set the maximum hop count of a BPDU packet to 25.
	`Ruijie(config)# spanning-tree max-hops 25`
Verification	● Run the **show spanning-tree** command to display the configuration.
	`Ruijie# show spanning-tree` `StpVersion : MSTP` `SysStpStatus : ENABLED` `MaxAge : 20` `HelloTime : 2` `ForwardDelay : 15` `BridgeMaxAge : 20` `BridgeHelloTime : 2` `BridgeForwardDelay : 15` `MaxHops: 25` `TxHoldCount : 3` `PathCostMethod : Long` `BPDUGuard : Disabled` `BPDUFilter : Disabled` `LoopGuardDef : Disabled` `###### mst 0 vlans map : ALL` `BridgeAddr : 00d0.f822.3344` `Priority: 0` `TimeSinceTopologyChange : 2d:0h:46m:4s` `TopologyChanges : 25` `DesignatedRoot : 0.001a.a917.78cc` `RootCost : 0` `RootPort : GigabitEthernet 0/1` `CistRegionRoot : 0.001a.a917.78cc`

	CistPathCost : 20000

6.4.8 Enabling PortFast-related Features

Configuration Effect

- After PortFast is enabled on a port, the port directly enters the forwarding state. However, since the Port Fast Operational State becomes disabled due to receipt of BPDUs, the port can properly run the STP algorithm and enter the forwarding state.
- If BPDU guard is enabled on a port, the port enters the error-disabled state after receiving a BPDU.
- If BPDU filter is enabled on a port, the port neither sends nor receives BPDUs.

Notes

- The global BPDU guard takes effect only when PortFast is enabled on a port.
- If BPDU filter is enabled globally, a PortFast-enabled port neither sends nor receives BPDUs. In this case, the host connecting directly to the PortFast-enabled port does not receive any BPDUs. If the port changes its Port Fast Operational State to Disabled after receiving a BPDU, BPDU filter automatically fails.
- The global BPDU filter takes effect only when PortFast is enabled on a port.

Configuration Steps

Enabling PortFast

- Optional.
- If a port connects directly to the network terminal, configure this port as a PortFast port.

Command	**spanning-tree portfast**
Parameter Description	N/A
Defaults	PortFast is disabled on a port by default.
Command Mode	Interface configuration mode
Usage Guide	After PortFast is enabled on a port, the port directly enters the forwarding state. However, since the Port Fast Operational State becomes disabled due to receipt of BPDUs, the port can properly run the STP algorithm and enter the forwarding state.

Enabling BPDU Guard

- Optional.
- If device ports connect directly to network terminals, you can enable BPDU guard on these ports to prevent BPDU attacks from causing abnormality in the spanning tree topology. A port enabled with BPDU guard enters the error-disabled state after receiving a BPDU.

- If device ports connect directly to network terminals, you can enable BPDU guard to prevent loops on the ports. The prerequisite is that the downlink device (such as the hub) can forward BPDU packets.

Command	**spanning-tree portfast bpduguard default**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	If BPDU guard is enabled on a port, the port enters the error-disabled state after receiving a BPDU. Run the **show spanning-tree** command to display the configuration.

Enabling BPDU Guard on an Interface

Command	**spanning-tree bpduguard enabled**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	If BPDU guard is enabled on a port, the port enters the error-disabled state after receiving a BPDU.

Enabling BPDU Filter

- Optional.
- To prevent abnormal BPDU packets from affecting the spanning tree topology, you can enable BPDU filter on a port to filter abnormal BPDU packets.

Command	**spanning-tree portfast bpdufilter default**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	If BPDU filter is enabled, corresponding ports neither send nor receive BPDUs.

Enabling BPDU Filter on an Interface

Command	**spanning-tree bpdufilter enabled**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	If BPDU filter is enabled on a port, the port neither sends nor receives BPDUs.

Verification

- Display the configuration.
- Run the **show spanning-tree** [**mst** *instance-id*] **interface** *interface-id* command to display the spanning tree configuration of the port.

Configuration Example

Enabling PortFast on a Port

Scenario **Figure 6-24**	Configuration Steps	● Configure Gi 0/3 of DEV C as a PortFast port and enable BPDU guard.
DEV C	`Ruijie(config)# int gi 0/3` `Ruijie(config-if-GigabitEthernet 0/3)# spanning-tree portfast` `%Warning: portfast should only be enabled on ports connected to a single` `host. Connecting hubs, switches, bridges to this interface when portfast is` `enabled,can cause temporary loops.` `Ruijie(config-if-GigabitEthernet 0/3)#spanning-tree bpduguard enable`
Verification	● Run the **show spanning-tree interface** command to display the port configuration.
DEV C	`Ruijie#show spanning-tree int gi 0/3` `PortAdminPortFast : Enabled` `PortOperPortFast : Enabled` `PortAdminAutoEdge : Enabled` `PortOperAutoEdge : Enabled` `PortAdminLinkType : auto`

```
PortOperLinkType : point-to-point

PortBPDUGuard : Enabled

PortBPDUFilter : Disabled

PortGuardmode  : None

###### MST 0 vlans mapped :ALL

PortState : forwarding

PortPriority : 128

PortDesignatedRoot : 0.00d0.f822.3344

PortDesignatedCost : 0

PortDesignatedBridge :0.00d0.f822.3344

PortDesignatedPortPriority : 128

PortDesignatedPort : 4

PortForwardTransitions : 1

PortAdminPathCost : 20000

PortOperPathCost : 20000

Inconsistent states : normal

PortRole : designatedPort
```

6.4.9 Enabling TC-related Features

Configuration Effect

- If TC protection is enabled on a port, the port deletes TC BPDU packets within a specified time (generally 4 seconds) after receiving them, preventing MAC and ARP entry from being removed.
- If TC guard is enabled, a port receiving TC packets filters TC packets received or generated by itself so that TC packets are not spread to other ports. In this way, possible TC attacks are efficiently prevented to keep the network stable.
- TC filter does not process TC packets received by ports but processes TC packets in case of normal topology changes.

Notes

- It is recommended to enable TC guard only when illegal TC attack packets are received in the network.

Configuration Steps

↘ Enabling TC Protection

- Optional.

- TC protection is disabled by default.

Command	spanning-tree tc-protection
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling TC Guard

- Optional.
- TC guard is disabled by default.
- To filter TC packets received or generated due to topology changes, you can enable TC guard.

Command	spanning-tree tc-protection tc-guard
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Enable TC guard to prevent TC packets from spreading.

Enabling TC Guard on an Interface

Command	spanning-tree tc-guard
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Enable TC guard to prevent TC packets from spreading.

Enabling TC Filter

- Optional.
- TC filter is disabled by default.
- To filter TC packets received on a port, you can enable TC filter on the port.

Command	spanning-tree ignore tc
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	If TC filter is enabled on a port, the port does not process received TC packets.

Verification

- Display the configuration.

Configuration Example

Enabling TC Guard on a Port

Configuration Steps	Enable TC guard on a port.
	`Ruijie(config)#int gi 0/1` `Ruijie(config-if-GigabitEthernet 0/1)#spanning-tree tc-guard`
Verification	• Run the **show run interface** command to display the TC guard configuration of the port.
	`Ruijie#show run int gi 0/1` `Building configuration...` `Current configuration : 134 bytes` `interface GigabitEthernet 0/1` ` switchport mode trunk` ` spanning-tree tc-guard`

Common Errors

- If TC guard or TC filter is incorrectly configured, an error may occur during packet forwarding of the network device. For example, when the topology changes, the device fails to clear MAC address in a timely manner, causing packet forwarding errors.

6.4.10 Enabling BPDU Source MAC Address Check

Configuration Effect

- Enable BPDU source MAC address check. After this, a device receives only BPDU packets with the source MAC address being the specified MAC address and discards other BPDU packets.

Notes

- When the switch connected to a port on a point-to-point link is determined, you can enable BPDU source MAC address check so that the switch receives the BPDU packets sent only by the peer switch.

Configuration Steps

Enabling BPDU Source MAC Address Check

- Optional.

- To prevent malicious BPDU attacks, you can enable BPDU source MAC address check.

Command	**bpdu src-mac-check** *H.H.H*
Parameter Description	*H.H.H*: Indicates an MAC address. The device receives only BPDU packets with this address being the source MAC address.
Command Mode	Interface configuration mode
Usage Guide	BPDU source MAC address check prevents BPDU packets from maliciously attacking switches and causing MSTP abnormal. When the switch connected to a port on a point-to-point link is determined, you can enable BPDU source MAC address check to receive BPDU packets sent only by the peer switch and discard all other BPDU packets, thereby preventing malicious attacks. You can enable BPDU source MAC address check in interface configuration mode for a specific port. One port can only filter one MAC address.

Verification

- Display the configuration.

Configuration Example

Enabling BPDU Source MAC Address Check on a Port

Configuration Steps	Enable BPDU source MAC address check on a port.
	`Ruijie(config)#int gi 0/1` `Ruijie(config-if-GigabitEthernet 0/1)#bpdu src-mac-check 00d0.f800.1234`
Verification	• Run the **show run interface** command to display the spanning tree configuration of the port.
	`Ruijie#show run int gi 0/1` `Building configuration...` `Current configuration : 170 bytes` `interface GigabitEthernet 0/1` ` switchport mode trunk` ` bpdu src-mac-check 00d0.f800.1234` `spanning-tree link-type point-to-point`

Common Errors

- If BPDU source MAC address check is enabled on a port, the port receives only BPDU packets with the configured MAC address being the source MAC address and discards all other BPDU packets.

6.4.11 Configuring Auto Edge

Configuration Effect

- Enable Auto Edge. If a designated port does not receive any BPDUs within a specified time (3 seconds), it is automatically identified as an edge port. However, if the port receives BPDUs, its Port Fast Operational State will become Disabled.

Notes

- Unless otherwise specified, do not disable Auto Edge.

Configuration Steps

Configuring Auto Edge

- Optional.
- Auto Edge is enabled by default.

Command	spanning-tree autoedge
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	If the designated port of a device does not receive a BPDU from the downlink port within a specific period (3 seconds), the device regards a network device connected to the designated port, configures the port as an edge port, and switches the port directly into the forwarding state. The edge port will be automatically identified as a non-edge port after receiving a BPDU. You can run the **spanning-tree autoedge disabled** command to disable Auto Edge.

Verification

- Display the configuration.

Configuration Example

Disabling Auto Edge on a Port

Configuration Steps	Disable Auto Edge on a port.
	`Ruijie(config)#int gi 0/1` `Ruijie(config-if-GigabitEthernet 0/1)#spanning-tree autoedge disabled`
Verification	• Run the **show spanning-tree interface** command to display the spanning tree configuration of the port.
	`Ruijie#show spanning-tree interface gi 0/1`

```
PortAdminPortFast : Disabled
PortOperPortFast : Disabled
PortAdminAutoEdge : Disabled
PortOperAutoEdge : Disabled
PortAdminLinkType : point-to-point
PortOperLinkType : point-to-point
PortBPDUGuard : Disabled
PortBPDUFilter : Disabled
PortGuardmode  : None

###### MST 0 vlans mapped :ALL
PortState : forwarding
PortPriority : 128
PortDesignatedRoot : 0.00d0.f822.3344
PortDesignatedCost : 0
PortDesignatedBridge :0.00d0.f822.3344
PortDesignatedPortPriority : 128
PortDesignatedPort : 2
PortForwardTransitions : 6
PortAdminPathCost : 20000
PortOperPathCost : 20000
Inconsistent states : normal
PortRole : designatedPort
```

Common Errors

If packet loss or Rx/Tx message delay exists, it is recommended to disable Auto Edge function.

6.4.12 Enabling Guard-related Features

Configuration Effect

- If root guard is enabled on a port, its roles on all instances are enforced as the designated port. Once the port receives configuration information with a higher priority, it enters the root-inconsistent (blocking) state. If the port does not receive configuration information with a higher priority within a period, it returns to its original state.

- Due to the unidirectional link failure, the root port or backup port becomes the designated port and enters the forwarding state if it does not receive BPDUs, causing a network loop. Loop guard is to prevent this problem.

Notes

- Root guard and loop guard cannot take effect on a port at the same time.

Configuration Steps

Enabling Root Guard

- Optional.
- The root bridge may receive configuration with a higher priority due to incorrect configuration by maintenance personnel or malicious attacks in the network. As a result, the current root bridge may lose its role, causing incorrect topology changes. To prevent this problem, you can enable root guard on a designated port of a device.

Command	spanning-tree guard root
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	If root guard is enabled, the current root bridge will not change due to incorrect configuration or illegal packet attacks.

Enabling Loop Guard

- Optional.
- You can enable loop guard on a port (root port, master port, or AP) to prevent it from failing to receive BPDUs sent by the designated bridge, increasing device stability. Otherwise, the network topology will change, possibly causing a loop.

Command	spanning-tree loopguard default
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Enabling loop guard on a root port or backup port will prevent possible loops caused by BPDU receipt failure.

Enabling Loop Guard on an Interface

Command	spanning-tree guard loop
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Enabling loop guard on a root port or backup port will prevent possible loops caused by BPDU receipt

	failure.

Disabling Guard

- Optional.

Command	**spanning-tree guard none**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Verification

- Display the configuration.

Configuration Example

Enabling Loop Guard on a Port

Scenario Figure 6-25	
Configuration Steps	• Configure DEV A as the root bridge and DEV B as a non-root bridge on a spanning tree. • Enable loop guard on ports Gi 0/1 and Gi 0/2 of DEV B.
DEV A	`Ruijie(config)#spanning-tree` `Ruijie(config)#spanning-tree mst 0 priority 0`
DEV B	`Ruijie(config)#spanning-tree` `Ruijie(config)# int range gi 0/1-2` `Ruijie(config-if-range)#spanning-tree guard loop`
Verification	• Run the **show spanning-tree interface** command to display the spanning tree configuration of the port.
DEV A	`Omitted.`

DEV B	Ruijie#show spanning-tree int gi 0/1 PortAdminPortFast : Disabled PortOperPortFast : Disabled PortAdminAutoEdge : Enabled PortOperAutoEdge : Disabled PortAdminLinkType : auto PortOperLinkType : point-to-point PortBPDUGuard : Disabled PortBPDUFilter : Disabled PortGuardmode : Guard loop ###### MST 0 vlans mapped :ALL PortState : forwarding PortPriority : 128 PortDesignatedRoot : 0.001a.a917.78cc PortDesignatedCost : 0 PortDesignatedBridge :0.001a.a917.78cc PortDesignatedPortPriority : 128 PortDesignatedPort : 17 PortForwardTransitions : 1 PortAdminPathCost : 20000 PortOperPathCost : 20000 Inconsistent states : normal PortRole : rootPort Ruijie#show spanning-tree int gi 0/2 PortAdminPortFast : Disabled PortOperPortFast : Disabled PortAdminAutoEdge : Enabled

```
PortOperAutoEdge : Disabled
PortAdminLinkType : auto
PortOperLinkType : point-to-point
PortBPDUGuard : Disabled
PortBPDUFilter : Disabled
PortGuardmode  : Guard loop

###### MST 0 vlans mapped :ALL
PortState : discarding
PortPriority : 128
PortDesignatedRoot : 0.001a.a917.78cc

PortDesignatedPort : 18
PortForwardTransitions : 1
PortAdminPathCost : 20000
PortOperPathCost : 20000
Inconsistent states : normal
PortRole : alternatePort
```

Common Errors

- If root guard is enabled on the root port, master port, or AP, the port may be incorrectly blocked.

6.4.13 Enabling BPDU Transparent Transmission

Configuration Effect

- If STP is disabled on a device, the device needs to transparently transmit BPDU packets so that the spanning tree between devices is properly calculated.

Notes

- BPDU transparent transmission takes effect only when STP is disabled. If STP is enabled on a device, the device does not transparently transmit BPDU packets.

Configuration Steps

Enabling BPDU Transparent Transmission

- Optional.
- If STP is disabled on a device that needs to transparently transmit BPDU packets, enable BPDU transparent transmission.

Command	bridge-frame forwarding protocol bpdu
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	In IEEE 802.1Q, the destination MAC address 01-80-C2-00-00-00 of the BPDU is used as a reserved address. That is, devices compliant with IEEE 802.1Q do not forward the BPDU packets received. However, devices may need to transparently transmit BPDU packets in actual network deployment. For example, if STP is disabled on a device, the device needs to transparently transmit BPDU packets so that the spanning tree between devices is properly calculated. BPDU transparent transmission takes effect only when STP is disabled. If STP is enabled on a device, the device does not transparently transmit BPDU packets.

Verification

- Display the configuration.

Configuration Example

Enabling BPDU Transparent Transmission

Scenario Figure 6-26	
	STP is enabled on DEV A and DEV C while is disabled on DEV B.
Configuration Steps	• Enable BPDU transparent transmission on DEV B so that STP between DEV A and DEV C can be correctly calculated.
DEV B	`Ruijie(config)#bridge-frame forwarding protocol bpdu`
Verification	• Run the **show run** command to check whether BPDU transparent transmission is enabled.
DEV B	`Ruijie#show run` `Building configuration...` `Current configuration : 694 bytes` `bridge-frame forwarding protocol bpdu`

6.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the statistics of packets sent and received on a port.	**clear spanning-tree counters** [**interface** *interface-id*]
Clears the STP topology change information.	**clear spanning-tree mst** *instance-id* **topochange record**

Displaying

Description	Command
Displays MSTP parameters and spanning tree topology information.	**show spanning-tree**
Displays the count of sent and received MSTP packets.	**show spanning-tree counters** [**interface** *interface-id*]
Displays MSTP instances and corresponding port forwarding status.	**show spanning-tree summary**
Displays the ports that are blocked by root guard or loop guard.	**show spanning-tree inconsistentports**
Displays the configuration of an MST region.	**show spanning-tree mst configuration**
Displays MSTP information of an instance.	**show spanning-tree mst** *instance-id*
Displays MSTP information of the instance corresponding to a port.	**show spanning-tree mst** *instance-id* **interface** *interface-id*
Displays topology changes of a port in an instance.	**show spanning-tree mst** *instance-id* **topochange record**
Displays MSTP information of all instances corresponding to a port.	**show spanning-tree interface** *interface-id*
Displays the forwarding time.	**show spanning-tree forward-time**
Displays the hello time.	**show spanning-tree hello time**
Displays the maximum hop count.	**show spanning-tree max-hops**
Displays the maximum number of BPDU packets sent per second.	**show spanning-tree tx-hold-count**
Displays the path cost calculation method.	**show spanning-tree pathcost method**

Debugging

System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Description	Command
Debugs all STPs.	**debug mstp all**
Debugs MSTP Graceful Restart (GR).	**debug mstp gr**

Debugs BPDU packet receiving.	**debug mstp rx**
Debugs BPDU packet sending.	**debug mstp tx**
Debugs MSTP events.	**debug mstp event**
Debugs loop guard.	**debug mstp loopguard**
Debugs root guard.	**debug mstp rootguard**
Debugs the bridge detection state machine.	**debug mstp bridgedetect**

Debugs the port role transition state machine.	**debug mstp roletran**
Debugs the port state transition state machine.	**debug mstp statetran**
Debugs the MSTP sending state machine.	**debug mstp transmit**

7 Configuring VLAN Group

7.1 Overview

Each virtual LAN (VLAN) group contains multiple VLANs. VLAN group function associates a wireless LAN (WLAN) with a VLAN group, achieving 1:N mapping between them, which assigns VLANs flexibly to WLAN-accessed stations (STAs).

VLAN assignment mode:

- After STAs pass 802.1X authentication, the authentication server assigns VLANs to STAs.

Protocols and Standards

- N/A

7.2 Applications

Application	Description
VLAN Assignment	The VLAN group assigns VLANs to WLAN-associated STAs.

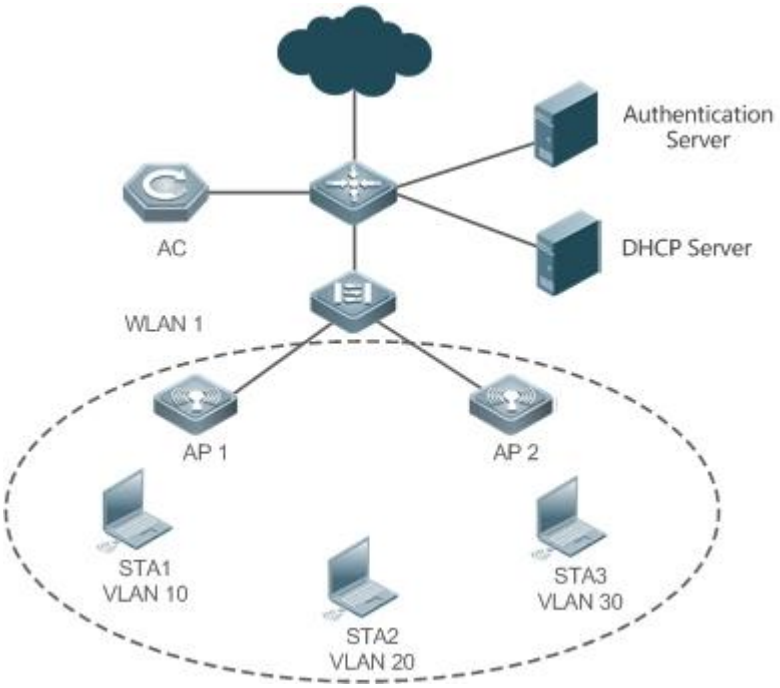
7.2.1 VLAN Assignment

Scenario

Multiple STAs access the same WLAN. VLANs are assigned to STAs based on the VLAN assignment mode of the VLAN group mapped to the current WLAN.

As shown in Figure 7-1, the VLAN group assigns VLANs to STA 1, STA 2, and STA 3 that have accessed WLAN 1.

Figure 7-1



Remarks	STA is a wireless device. AP 1 and AP 2 are the access points through which STAs access the wired network. AC is a wireless access controller. It connects with APs through the wired network to manage APs in a unified manner. WLAN 1 is a wireless local area network.

7.3 Features

Basic Concepts

VLAN Group

Multiple VLANs are added to a VLAN group. When STAs access a WLAN, VLANs are assigned to the STAs based on the VLAN assignment mode of the VLAN group mapped to the current WLAN.

VLAN Assignment Mode

Each VLAN group can assign VLANs based on 802.1X.

Overview

Feature	Description

802.1X-based VLAN Assignment	You can plan VLANs to be assigned after STAs pass 802.1X authentication.

7.3.1 802.1X-based VLAN Assignment

Working Principle

Before authentication, an STA belongs to the default VLAN of a VLAN group mapped to the currently accessed WLAN.

The STA will be authenticated in the default VLAN. After authentication succeeds, the authentication server determines whether to assign a VLAN. If yes, the packets subsequently sent by the STA will be automatically redirected to the assigned VLAN. If no, the packets will be transmitted in the default VLAN of the VLAN group.

7.4 Configuration

Configuration	Description and Command	
Configuring a VLAN Group	⚠ (Mandatory) It is used to create a VLAN group and configure a VLAN list, the VLAN assignment mode, and default VLAN.	
	vlan-group *group-id*	Creates a VLAN group.
	vlan-list *vlan-list*	Configures a VLAN list for a VLAN group.
	vlan-assign-mode XX	Specifies the VLAN assignment mode for a VLAN group.
	default-vlan XX	Configures the default VLAN for a VLAN group.
Configuring WLAN-VLAN Group Mapping	⚠ (Mandatory) It is used to configure the mapping between a WLAN and a VLAN group.	
	vlan-group *group-id*	Configures WLAN-VLAN group mapping on APs.
	interface-mapping *wlan-id* **group** *group-id*	Configures WLAN-VLAN group mapping on ACs.

7.4.1 Configuring a VLAN Group

Configuration Effect

- Create a VLAN group and complete configurations related to the VLAN group.

Notes

- N/A

Configuration Steps

↘ **Creating a VLAN Group**

- Mandatory.

Configuring a VLAN List for a VLAN Group

- Mandatory. Ensure that VLANs have been created.

Configuring the VLAN Assignment Mode for a VLAN Group

- Mandatory.
- Use this command to implement the VLAN assignment policy of a VLAN group.

Configuring the Default VLAN for a VLAN Group

- Mandatory in 802.1X-based assignment mode.
- The default VLAN takes effect when the current WLAN is in 802.1X-based assignment mode, that is, when the authentication server assigns the default VLAN before 802.1X authentication succeeds.

Verification

- Check the configurations of the VLAN group.

Configuration Example

Configuring a VLAN Group

Configuration Steps	• Create VLAN Group 10. • Set the VLAN assignment mode to 802.1X-based mode. • Configure a VLAN list that contains VLAN 1 to VLAN 10. • Set the default VLAN to VLAN 1.
	Ruijie# configure terminal Ruijie(config)# vlan-group 10 Ruijie(config-vlan-group)# vlan-assign-mode dot1x Ruijie(config-vlan-group)# vlan-list 1-10 Ruijie(config-vlan-group)# default-vlan 1 Ruijie(config-vlan-group)# end
Verification	• Check whether the configurations of VLAN Group 10 are correct.
	Ruijie#show vlan-group 10 vlan-group id mode default-vlan vlan-list ------------ ---------- ---------- ---------- 10 dot1x 1 1-10

Common Errors

- A VLAN configured in a VLAN list does not exist.
- The default VLAN configured does not exist in the VLAN list.

⚠ The ID of a created VLAN group ranges from 1 to 128.

A VLAN group contains a maximum of 128 VLANs.

7.4.2 Configuring WLAN-VLAN Group Mapping

Configuration Effect

- Configure the mapping between a WLAN and a VLAN group so that STAs can be associated with the WLAN.

Notes

- N/A

Configuration Steps

Configure WLAN-VLAN Group Mapping

- Mandatory.

Verification

- Check whether the mapping between a WLAN and a VLAN group is correct.

Configuration Example

Configure WLAN-VLAN Group Mapping on ACs

Configuration Steps	• Enter the AP group configuration mode. • Configure the WLAN-VLAN group mapping.
	`Ruijie(config)# ap-group default` `Ruijie(config-ap-group)# interface-mapping 100 vlan-group 100`
Verification	• Run the **show running** command to check whether the configurations are correct.

Configuration Example of 802.1X-based VLAN Assignment

In the WLAN scenario shown in Figure 7-2, leaders, employees, and visitors are differentiated to access the WLAN with different privilege levels. The following configurations are required:

- Create VLAN Group 100, including VLAN 10, VLAN 20, and VLAN 30.
- Map WLAN 1 to VLAN Group 100. When STAs access WLAN 1, the authentication server performs 802.1X authentication for the STAs. After the authentication is complete, the authentication server assigns VLAN 10 to leaders, VLAN 20 to employees, and VLAN 30 to visitors.

Scenario **Figure 7-2**	Configuration Steps	● If the WLAN-VLAN mapping is 1:N, different VLANs can be assigned to STAs in the same WLAN. ● Set the WLAN authentication mode to 802.1X authentication so that different VLANs can be assigned to different STAs.
AP1 & AP2 **AC**	APs apply the centralized forwarding in fit AP architecture by default, and are managed by ACs in a unified manner. Step 1: Create VLANs respectively for different types of users. Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# vlan range 10 , 20 , 30 Ruijie(config-vlan-range)# exit Step 2: Create a VLAN group, add VLAN 10, VLAN 20, and VLAN 30 to the group, and configure VLAN 30 as the default VLAN for visitors. Ruijie(config)# vlan-group 100 Ruijie(config-vlan-group)# vlan-assign-mode dot1x Ruijie(config-vlan-group)# vlan-list 10 , 20 , 30 Ruijie(config-vlan-group)# default-vlan 30 Ruijie(config-vlan-group)# exit Step 3: Create WLAN 1, with the WLAN authentication mode set to 802.1X authentication and the encryption mode set to Advanced Encryption Standard (AES). Ruijie(config)# wlan-config 1 office_wifi Ruijie(config-wlan)# exit Ruijie(config)# wlansec 1

Authentication Server	Ruijie(wlansec)# security wpa enable Ruijie(wlansec)# security wpa akm 802.1x enable Ruijie(wlansec)# security wpa ciphers aes enable Step 4: Configure the mapping between WLAN 1 and VLAN Group 100. Ruijie(config)# ap-group default Ruijie(config-ap-group)# interface-mapping 1 vlan-group 100 Before establishing a new STA type on the authentication server, you need to configure a specific VLAN for the assignment.
Verification	● Check the VLAN group configurations on the AC.
AC	Ruijie# show vlan-group VLAN-Group ID Default VLAN Assign-Mode VLAN-List ---------- ---------- ---------- ---------- 100 30 dot1x 10，20，30

Common Errors

- N/A

7.5 Monitoring

Clearing

N/A

Displaying

Description	Command
Displays the VLAN group information.	**show vlan-group** [*group-id*]

Debugging

⚠ System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Description	Command
Debugs the VLAN group status.	**debug bridge vgoup**

8 Configuring PPPoE-CLIENT

8.1 Overview

PPPoE: Point-to-point Protocol Over Ethernet

Ruijie products support the PPPoE client on Ethernet interfaces, and are therefore able to connect to a host network by accessing a remote hub through a simple access device. The PPPoE protocol enables the PPPoE server to control each access client and perform relevant accounting.

Ruijie products support two dialing modes: Dial-on-Demand Routing (DDR) mode and no Dial-on-Demand Routing (DDR) but always online.

- The PPPoE client is applicable in scenarios where Internet access is implemented through ADSL.

The following sections describe the PPPoE client only.

Protocols and Standards

- RFC2516: A Method for Transmitting PPP Over Ethernet (PPPoE)
- RFC1661: The Point-to-Point Protocol (PPP)

8.2 Applications

Application	Description
ADSL Scenario	In a scenario where Internet access is implemented through the Asymmetric Digital Subscriber Line (ADSL) technology, the device provides dialup and packet forwarding functions.

8.2.1 ADSL Scenario

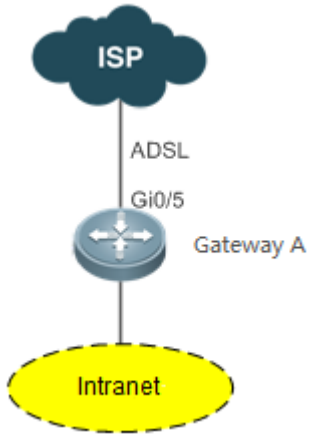
Scenario

In a scenario where Internet access is implemented through ADSL, the device provides dialup and packet forwarding functions.

The dialup networking scenario is illustrated with Figure 8-1 as an example.

- The dialup function is enabled on the device. The device connects to a remote Internet service provider (ISP) over an ADSL line, and obtains Internet access capability.
- Intranet PCs access the Internet through the device.

Figure 8-1



Corresponding Protocols

- Enable the dialup function on the device, and dial up to the Internet over the ADSL line.

8.3 Features

Basic Concepts

ISP

A network operator who provides users with Internet access service, information service, and value-added services (VASs).

ADSL

A line on which users dial up to the Internet.

Data Flow

A flow of packets only forwarded by the device.

Interested Flow

A specific type of packets defined by users during configuration, which can trigger the device to start dialup.

Overview

Feature	Description
Dialup to the Internet	In a scenario where Internet access is implemented through the Asymmetric Digital Subscriber Line (ADSL) technology, the device provides dialup and packet forwarding functions.

8.3.1 Dialup to the Internet

The device has Internet access capability after the dialup is complete; therefore, hosts in the intranet also have Internet access capability.

Working Principle

Dialup corresponds to the negotiation process, whereas Internet access corresponds to the packet forwarding process.

Negotiation can be further divided into three parts: protocol negotiation, protocol keepalive, and protocol termination.

Protocol Negotiation

Protocol negotiation is divided into PPPoE negotiation and PPP negotiation.

During PPPoE negotiation, both parties confirm a unique peer, record the peer's MAC address, and establish a unique session ID.

During PPP negotiation, the server checks the client's authentication information. If the client passes the authentication, the server allocates an IP address to the client. If the client has already been configured with an IP address and the configured IP address meets the server's requirements, the server will agree to use this IP address as the IP address of the client.

After both protocols are up, the device has Internet access capability and prepares a Layer 2 (L2) header that is necessary for data packet encapsulation.

Protocol Keepalive

After PPP is up, both parties periodically send LCP heartbeat packets to each other. If the party at one end does not receive any heartbeat response from the other party, it actively terminates the protocol.

Protocol Termination

In certain cases, either party may actively terminate the protocol.

The initiating party sends a PPP termination packet to end the current PPP session, and then sends a PPPoE termination packet to end the current PPPoE session.

After receiving the PPP termination packet, the passive party returns an acknowledgement packet to agree to the termination of the PPP session; and after receiving the PPPoE termination packet, the passive party returns another acknowledgement packet to agree to the termination of the PPPoE session.

Once either party receives a PPPoE termination protocol, the PPP session and the PPPoE session will immediately terminate, even if it has not received any PPP termination protocol.

Packet Forwarding

Packet sending process: When a data packet is routed to the dialer interface, the device encapsulates the data packet with the prepared L2 header information and ultimately sends the data packet from a physical port.

Packet receiving process: After a packet arrives at a physical port, the device marks the Layer 3 (L3) header position of the packet, executes the next service, and ultimately sends the packet to a host in the intranet.

Related Configuration

Configuring the Ethernet Interface

By default, the following functions are disabled and there is no corresponding default value.

Run the **pppoe enable** command to enable the PPPoE client function on the interface.

Run the **no pppoe enable** command to disable the PPPoE client function on the interface.

Run the **pppoe-client dial-pool-number** *pool-number* command to bind the Ethernet interface to a specific logical dialer pool.

Run the **no pppoe-client dial-pool-number** *pool-number* command to unbind the Ethernet interface from the specific logical dialer pool.

Configuring the Logical Interface

By default, the following functions are disabled.

Run the **interface dialer** *dialer-number* command to add a specific logical interface and enter the configuration mode of the logical interface.

Run the **no interface dialer** *dialer-number* command to delete the specific logical interface.

Run the **ip address negotiate** command to configure negotiation-based IP address acquisition.

Run the **no ip address negotiate** command to remove the configuration of negotiation-based IP address acquisition.

Run the **dialer pool** *number* command to associate a dialer pool, which corresponds to the dialer pool configured on the Ethernet interface.

Run the **no dialer pool** *number* command to remove the association with the dialer pool.

Run the **encapsulation ppp** command to configure the encapsulation protocol PPP. PPPoE is established on the basis of PPP.

Run the **no encapsulation** command to remove the encapsulation protocol configuration.

Run the **mtu** *1488* command to set the Maximum Transmit Unit (MTU) to 1488.

Run the **no mtu** command to remove the MTU configuration.

Run the **dialer-group** *dialer-group-number* command to associate a dialer triggering rule, which corresponds to the dialer-list.

Run the **no dialer-group** command to remove the configuration of the dialer triggering rule.

Run the **ppp chap hostname** *username* command to configure the user name for CHAP authentication.

Run the **no ppp chap hostname** command to remove the user name configuration for CHAP authentication.

Run the **ppp chap password** *password* command to configure the password for CHAP authentication.

Run the **no ppp chap password** command to remove the password configuration for CHAP authentication.

Run the **ppp pap sent-username** *username* **password** *password* command to configure the user name and password for PAH authentication.

Run the **no ppp pap sent-username** command to remove the user name and password configuration for PAH authentication.

Configuring Mandatory Global Parameters

By default, the following functions are disabled and shall be configured according to actual requirements. If other functional modules need to be used together, you also need to configure other global parameters.

Run the **dialer-list number protocol** *protocol-name* { **permit** | **deny** | **list** *access-list-number* } command to define a dialer triggering rule.

Run the **no dialer-list number** command to delete the configured dialer triggering rule.

Run the **ip route** *0.0.0.0 0.0.0.0* **dialer** *dialer-number* [**permanent**] command to configure a route. If you specify the **permanent** option, the route will be always valid, even if the logical interface is within the enable-timeout period, in which case the logical interface will be down.

Run the **no ip route** *0.0.0.0 0.0.0.0* **dialer** *dialer-number* command to remove the route.

8.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of the PPPoE Client	Mandatory configuration.	
	pppoe enable	Enables the PPPoE client function.
	pppoe-client dial-pool-number *number* { **dial-on-demand** | **no-ddr**	Binds a logical dialer pool and specifies the dialing mode.
	interface dialer *dialer-number*	Adds a specific logical interface and enters the configuration mode of the logical interface.
	ip address { **negotiate** | *ip-addr subnet-mask* }	Configures the IP address acquisition mode.
	dialer pool *number*	Associates a dialer pool.
	encapsulation ppp	Configures the encapsulation protocol PPP.
	mtu *1488*	Sets the MTU to 1488.
	dialer-group *dialer-group-number*	Associates a dialer triggering rule.
	ppp chap hostname *username*	Configures the user name for CHAP authentication.
	ppp chap password *password*	Configures the password for CHAP authentication.
	ppp pap sent-username *username* **password** *password*	Configures the user name and password for PAP authentication.
	dialer-list number protocol *protocol-name* { **permit** | **deny** | **list** *access-list-number* }	Defines a dialer triggering rule.

8.4.1 Configuring Basic Functions of the PPPoE Client

Networking Requirements

- The device initiates PPPoE negotiation, and completes the negotiation process, protocol keepalive, and protocol termination.
- The device obtains Internet access capability after the negotiation is complete, and starts to forward a data flow which is routed to the dialer interface.

Notes

- After the kernel module is uninstalled, users can still perform configuration management but negotiation and data flow forwarding cannot be performed.

Configuration Steps

Enabling the PPPoE Client Function

- The configuration is mandatory.
- Perform this configuration in Ethernet interface configuration mode.
- Enable the PPPoE client function.

Binding a Logical Dialer Pool and Specifying the Dialing Mode

- The configuration is mandatory.
- Perform this configuration in Ethernet interface configuration mode.
- Bind the Ethernet interface to a specific logical dialer pool and specify the dialer mode.

Adding a Specific Logical Interface and Entering the Configuration Mode of the Logical Interface

- The configuration is mandatory.
- Perform this configuration in global configuration mode.
- Add a specific logical interface and enter its configuration mode.

Configuring the Way of Acquiring the IP Address of the Logical Interface

- The configuration is mandatory.
- Perform this configuration in logical interface configuration mode.
- Configure the way of acquiring the IP address of the logical interface.

Associating a Dialer Pool

- The configuration is mandatory.
- Perform this configuration in logical interface configuration mode.
- Associate the logical interface with a specific dialer pool.

Configuring the Encapsulation Protocol

- The configuration is mandatory.
- Perform this configuration in logical interface configuration mode.
- Configure the encapsulation protocol PPP on the logical interface.

Configuring the MTU of the Logical Interface

- The configuration is mandatory.
- Perform this configuration in logical interface configuration mode.
- Set the MTU of the logical interface to 1488.

Associating a Dialer Triggering Rule

- The configuration is mandatory.
- Perform this configuration in logical interface configuration mode.
- Associate a dialer triggering rule.

Configuring the User Name for CHAP Authentication

- The configuration is mandatory.
- Perform this configuration in logical interface configuration mode.
- Configure the user name for CHAP authentication.

Configuring the Password for CHAP Authentication

- The configuration is mandatory.
- Perform this configuration in logical interface configuration mode.
- Configure the password for CHAP authentication.

Configuring the User Name and Password for PAP Authentication

- The configuration is mandatory.
- Perform this configuration in logical interface configuration mode.
- Configure the user name and password for PAP authentication.

Defining a Dialer Triggering Rule

- The configuration is mandatory.
- Perform this configuration in global configuration mode.
- Define a dialer triggering rule.

Verification

- Check whether the dialer interface has acquired an IP address.
- Check whether a correct dialer interface route entry has been established on the device.

Related Commands

Enabling the PPPoE Client Function

Command Syntax	**pppoe enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Configuration	The interface on which the PPPoE client will be enabled must be a WAN Ethernet interface.

Usage	

Binding a Logical Dialer Pool and Specifying the Dialing Mode

Command Syntax	**pppoe-client dial-pool-number** *number* { **dial-on-demand** | **no-ddr**
Parameter Description	*number*: number of the dialer pool
Command Mode	Interface configuration mode
Configuration Usage	The PPPoE client function must be enabled on the interface first.

Adding a Specific Logical Interface and Entering its Configuration Mode

Command Syntax	**interface dialer** *dialer-number*
Parameter Description	*dialer-number*: interface number
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring the Way of Acquiring the IP Address of the Logical Interface

Command Syntax	**ip address** { **negotiate** | *ip-addr subnet-mask* }
Parameter Description	*ip-addr*: manually configured IP address *subnet-mask*: manually configured subnet mask
Command Mode	Interface configuration mode
Configuration Usage	If you select **negotiate**, the IP address of the dialer interface will be acquired through negotiation. If you manually specify the IP address of the dialer interface, the peer's consent is required during negotiation for the device to work properly.

Associating a Dialer Pool

Command Syntax	**dialer pool** *number*
Parameter Description	*number*: number of the dialer pool
Command Mode	Interface configuration mode
Configuration Usage	An Ethernet interface will be selected from the dialer pool as the dialer interface to perform dialing.

Configuring the Encapsulation Protocol

Command Syntax	**encapsulation ppp**
Parameter Description	N/A
Command Mode	Interface configuration mode
Configuration Usage	N/A

Configuring the MTU of the Logical Interface

Command Syntax	**mtu** *1488*
Parameter Description	N/A
Command Mode	Interface configuration mode
Configuration Usage	Because Internet access is implemented through the PPPoE protocol, the L2 header of a packet is longer than that of a common Ethernet packet.

Associating a Dialer Triggering Rule

Command Syntax	**dialer-group** *dialer-group-number*
Parameter Description	*dialer-group-number*: number of the dialer triggering rule
Command Mode	Interface configuration mode
Configuration Usage	If the DDR mode is specified, the device will be triggered to perform dialing only when a packet meeting the rule is routed to the dialer interface. If the no-DDR mode is specified, the configuration will not take effect on the device.

Configuring the User Name for CHAP Authentication

Command Syntax	**ppp chap hostname** *username*
Parameter Description	*username*: user name
Command Mode	Interface configuration mode
Configuration Usage	N/A

Configuring the Password for CHAP Authentication

Command Syntax	**ppp chap password** *password*
Parameter Descr	*password*: password

iption	
Command Mode	Interface configuration mode
Configuration Usage	N/A

Configuring the User Name and Password for PAP Authentication

Command Syntax	**ppp pap sent-username** *username* **password** *password*
Parameter Description	*username*: user name *password*: password
Command Mode	Interface configuration mode
Configuration Usage	N/A

Defining a Dialer Triggering Rule

Command Syntax	**dialer-list number protocol** *protocol-name* **ip**{ **permit** | **deny** | **list** *access-list-number* }
Parameter Description	*protocol-name*: protocol name *access-list-number*: ACL number
Command Mode	Global configuration mode
Configuration Usage	N/A

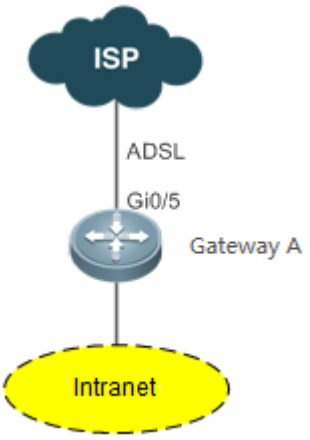
Configuration Example

The following configuration example describes configuration related to the PPPoE client only.

In the ADSL scenario, enable the PPPoE client function and access the Internet through an ADSL line.

Scenario

Figure 8-2



Configuration Steps	● Enable the PPPoE client function on the device, and add the interface Gi0/5 to the dialer pool.
A	A# configure terminal A(config)# interface GigabitEthernet 0/5 A(config-if)# pppoe enable A(config-if)# pppoe-client dial-pool-number 1 no-ddr dial-on-demand A(config-if)# exit A(config)# interface dialer 1 A(config-if)# ip address negotiate A(config-if)# mtu 1488 A(config-if)# encapsulation ppp A(config-if)# ip nat outside A(config-if)# dialer pool 1 A(config-if)# dialer-group 1 A(config-if)# ppp chap hostname pppoe A(config-if)# ppp chap password pppoe A(config-if)# ppp pap sent-username pppoe password pppoe A(config-if)# exit A(config)# access-list 1 permit any A(config)# dialer-list 1 protocol ip permit A(config)# ip nat inside source list 1 interface dialer 1 A(config)# ip route 0.0.0.0 0.0.0.0 dialer 1 A(config)# end A#
Verification	Run the **show ip interface brief | in dialer** *1* command to check whether the dialer interface has acquired an IP address. Run the **show ip route** command to check whether a correct dialer interface route entry has been

	established. A# show ip interface brief | in dialer 1 dialer 1 49.1.1.127/32 YES UP A# show ip route Codes: C - connected, S - static, R - RIP, B - BGP O - OSPF, IA - OSPF inter area N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 ia - IS-IS inter area, * - candidate default Gateway of last resort is 0.0.0.0 to network 0.0.0.0 S* 0.0.0.0/0 is directly connected, dialer 1 C 10.10.3.0/24 is directly connected, GigabitEthernet 0/0 C 10.10.3.1/32 is local host. C 10.202.172.1/32 is directly connected, dialer 1 C 49.1.1.127/32 is local host.

Common Errors

- The negotiation fails because the user name or password is incorrect.
- Intranet hosts cannot access the Internet because NAT configuration is incorrect.
- Intranet hosts cannot access the Internet because route configuration is incorrect.

8.5 Monitoring

Clearing Various Information

If you run the **clear pppoe tunnel** command while the device is operating, packet forwarding will be interrupted due to tunnel clearance.

Function	Command
Clears statistics about the DDR dialer interface.	**clear dialer** [*interface-type interface-number*]
Clears the tunnel.	**clear pppoe tunnel**

Displaying the Running Status

Function	Command

Displays information about the DDR dialer.	**show dialer** [**interface** type number] [**maps**] [**pools**]
Displays PPPoE status information.	**show pppoe** { **ref** | **session** | **tunnel** }

Displaying Debugging Information

System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Command	Function
debug dialer { **pkt** | **mlp|callback|event** }	Enables the DDR debugging switch.
debug ppp [**authentication** | **error** | **event** | **negotiation** | **packet**]	Enables the PPP negotiation debugging switch.
debug pppoe [**datas** | **errors** | **events** | **packets**]	Enables the PPPoE negotiation debugging switch.

9 Configuring RLDP

9.1 Overview

The Rapid Link Detection Protocol (RLDP) achieves rapid detection of unidirectional link failures, directional forwarding failures and downlink loop failures of an Ethernet. When a failure is found, relevant ports will be closed automatically according to failure treatment configuration or the user will be notified to manually close the ports to avoid wrong flow forwarding or an Ethernet layer-2 loop.

9.2 Applications

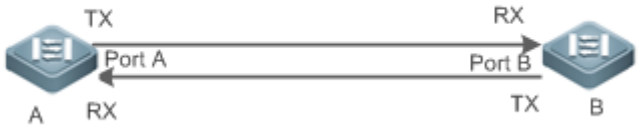
Application	Description
Unidirectional Link Detection	Detect a unidirectional link failure.
Bidirectional Forwarding Detection	Detect a bidirectional link failure.
Downlink Loop Detection	Detect a link loop.

9.2.1 Unidirectional Link Detection

Scenario

As shown in the following figure, A is connected to B via optical fiber. The two lines are the Tx and Rx lines of optical fiber. Unidirectional link detection is enabled on A and B. If any of the Tx of Port A, Rx of Port B, Tx of Port B and Rx of Port A fails, a unidirectional failure will be detected and treated under the RLDP. If the failure is eliminated, the administrator may manually restore the RLDP on A and B and resume detection.

Figure 9-1



Remarks	A and B are layer-2 or layer-3 switches. The Tx of Port A of A is connected to the Rx of Port B of B. The Rx of Port A of A is connected to the Tx of Port B of B.

Deployment

- Global RLDP is enabled.
- Configure unidirectional link detection under Port A and Port B and define a method for failure treatment.

9.2.2 Bidirectional Forwarding Detection

Scenario

As shown in the following figure, A is connected to B via optical fiber, and the two lines are Tx and Rx lines of optical fiber. Unidirectional link detection is enabled on A and B. If the Tx of Port A, Rx of Port B, Rx of Port A and Tx of Port B all fail, a bidirectional failure will be detected and treated under the RLDP. If the failure is eliminated, the administrator may manually restore the RLDP on A and B and resume detection.

Figure 9-2

Remarks	A and B are layer-2 or layer-3 switches. The Tx of Port A of A is connected to the Rx of Port B of B. The Rx of Port A of A is connected to the Tx of Port B of B.

Deployment

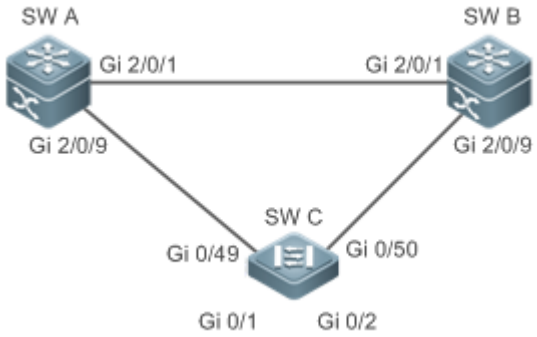
- Global RLDP is enabled.
- Configure BFD under Port A and Port B and define a method for failure treatment.

9.2.3 Downlink Loop Detection

Scenario

As shown in the following figure, A, B and C are connect into a loop. Downlink loop detection is enabled on A, and a loop is detected and treated.

Figure 9-3



Remarks	A, B and C are layer-2 or layer-3 switches. A, B and C are interconnected via exchange ports.

Deployment

- Global RLDP is enabled on A.
- Configure downlink loop detection on the Gi 2/0/1 and Gi 2/0/9 ports of A, and define a method for failure treatment.

9.3 Features

Most Ethernet link detection mechanisms detect link connectivity through automatic physical-layer negotiation. However, in some cases devices are connected on the physical layer and operate normally but layer-2 link communication is disabled or abnormal. The RLDP recognizes a neighbor device and detects a link failure through exchanging Prob packets, Echo packets or Loop packets with the device.

Basic Concepts

Unidirectional Link Failure

A unidirectional link failure occurs in case of a cross-connected optical fiber, a disconnected optical fiber, an open-circuit optical fiber, one open-circuit line in a twisted-pair cable, or unidirectional open circuit of an intermediate device between two devices. In such cases, one end of a link is connected and the other disconnected so that flow is forwarded wrongly or a loop guard protocol (for example, the STP) fails.

Bidirectional Link Failure

A bidirectional link failure occurs in case of two optical fibers, two open-circuit lines in a twisted-pair cable, or bidirectional open circuit of an intermediate device between two devices. In such cases, the both ends of a link are disconnected so that flow is forwarded wrongly.

Loop Failure

A downlink device is wrongly connected to form a loop, resulting in a broadcast storm.

RLDP Packet

The RLDP defines three types of packets: Prob packets, Echo packets and Loop packets.

- Prob packets are layer-2 multicast packets for neighbor negotiation, and unidirectional or bidirectional link detection. The default encapsulation format is SNAP, which changes automatically to EthernetII if a neighbor sends EthernetII packets.
- Echo packets are layer-2 unicast packets as response to Prob packets and used for unidirectional or bidirectional link detection. The default encapsulation format is SNAP, which changes automatically to EthernetII if a neighbor sends EthernetII packets.
- Loop packets are layer-2 multicast packets for downlink loop detection. They can only be received. The default encapsulation format is SNAP.

RLDP Detection Interval and Maximum Detection Times

A detection interval and the maximum detection times can be configured for the RLDP. A detection interval determines the period of sending Prob packets and Loop packets. When a device receives a Prob packet, it replies with an Echo packet immediately. A detection interval and the maximum detection times determine the maximum detection time (equal to a detection interval × the maximum detection times + 1) for unidirectional or bidirectional link detection. If neither Prob nor Echo packet from a neighbor can be received within the maximum detection time, the treatment of unidirectional or bidirectional failure will be triggered.

RLDP Neighbor Negotiation

When configured with unidirectional or bidirectional link detection, a port can learn a peer-end device as its neighbor. One port may learn one neighbor, which is variable. If negotiation is enabled, unidirectional or bidirectional link detection starts after a port finds a neighbor through negotiation, which succeeds when a port receives a Prob packet from the neighbor. However, if the RLDP is enabled under a failure, the port cannot learn a neighbor so that detection cannot start. In this case, recover the link state before enabling the RLDP.

Treatment for Failed Port under RLDP

- Warning: Only print Syslog to indicate a failed port and a failure type.
- Shutdown SVI: Print Syslog, and then inquire an SVI according to the Access VLAN or Native VLAN of a port and shut down the SVI if the port is a physical exchange port or layer-2 AP member port.
- Port violation: Print Syslog, and configure a failed port as in violation state, and the port will enter Linkdown state physically.
- Block: Print Syslog, and configure the forward state of a port as Block, and the port will not forward packets.

Recovery of Failed Port under RLDP

- Manual reset: Manually reset all failed ports to initialized state and restart link detection.
- Manual or automatic errdisable recovery: Recover all failed ports to initialized state manually or regularly (30s by default and configurable) and restart link detection.
- Automatic recovery: Under unidirectional or bidirectional link detection, if the treatment for failed ports is not specified as port violation, recover ports to initialized state based on Prob packets and restart link detection.

Port State under RLDP

- normal: Indicates the state of a port after link detection is enabled.
- error: Indicates the state of a port after a unidirectional or bidirectional link failure or a loop failure is detected.

Overview

Feature	Description

Deploying RLDP Detection	Enable unidirectional or bidirectional link detection or downlink loop detection for failures and implement treatment.

9.3.1 Deploying RLDP Detection

The RLDP provides unidirectional link detection, bidirectional forwarding detection and downlink loop detection.

Working Principle

Unidirectional Link Detection

When this function is enabled, a port sends Prob packets and receives Echo packets from a neighbor regularly as well as receiving Prob packets from a neighbor and replying with Echo packets. Within the maximum detection time, if the port receives Prob packets but no Echo packets, or none of them, treatment for a unidirectional failure will be triggered and detection will stop.

Bidirectional Forwarding Detection

When this function is enabled, a port sends Prob packets and receives Echo packets from a neighbor regularly as well as receiving Prob packets from a neighbor and replying with Echo packets. Within the maximum detection time, if the port receives neither Prob packets nor Echo packets from a neighbor, treatment for a bidirectional failure will be triggered and detection will stop.

Downlink Loop Detection

When this function is enabled, a port sends Loop packets regularly. In the following cases, a loop failure will be triggered after the same port or a different port receives the packets: in one case, the egress and ingress ports are the same routed port or layer-3 AP member port; in another case, the egress and ingress ports are exchange ports or layer-2 AP member ports in a same default VLAN and in Forward state. Treatment for the failure will be implemented and detection will stop.

Related Configuration

- Configuring RLDP Detection

By default, RLDP detection is disabled.

You may run the global command **rldp enable** or the interface command **rldp port** to enable RLDP detection and specify a detection type and treatment.

You may run the **rldp neighbor-negotiation** command to neighbor negotiation, the **rldp detect-interval** to specify a detection interval, the **rldp detect-max** to specify detection times, or the **rldp reset** to recover a failed port.

9.4 Configuration

Configuration	Description and Command	
Configuring Basic RLDP Functions	⚠ (Mandatory) It is used to enable RLDP detection under global configuration mode.	
	rldp enable	Enables global RLDP detection on all ports.

	(Mandatory)It is used to specify under interface configuration mode a detection type and failure treatment for an interface.	
	rldp port	Enables RLDP detection on a port and specifies a detection type and failure treatment.
	(Optional)It is used to configure a detection interval, detection times and neighbor negotiation under global configuration mode.	
	rldp detect-interval	Modifies global RLDP parameters on all ports, such as the detection interval, maximum detection times and neighbor negotiation.
	rldp detect-max	
	rldp neighbor-negotiation	
	(Optional) It is used under privileged mode.	
	rldp reset	Recovers all ports.

9.4.1 Configuring Basic RLDP Functions

Configuration Effect

- Enable RLDP unidirectional link detection, bidirectional forwarding detection, or downlink loop detection to discover failures.

Notes

- Loop detection is effective to all member ports of an AP when configured on one of the ports. Unidirectional link detection and bidirectional forwarding detection are effective only on an AP member port.
- The loop detection on a physical port added to an AP shall be configured the same as that of the other member ports. There are two cases. First, if loop detection is not configured on a newly-added port but on the existing member ports, the new port adopts the configuration and detection results of the existing ports. Second, if a newly-added port and the existing member ports have different loop detection configuration, the new port adopts the configuration and detection results of the existing ports.
- When configuring the RLDP on an AP port, you may configure failure treatment only as "shutdown-port", to which other configurations will be modified.
- When "shutdown-port" is configured on a port, RLDP detection cannot be restored in case of a failure. After troubleshooting, you may run the **rldp reset** or **errdisable recovery** command to restore the port and resume detection. For configuration of the **errdisable recovery** command, please refer to the *Configuring Interface.doc*.

Configuration Steps

Enabling RLDP

- Mandatory.
- Enable RLDP detection on all ports under global configuration mode.

Enabling Neighbor Negotiation

- Optional.
- Enable the function under global configuration mode, and port detection will be started under successful neighbor negotiation.

Configuring Detection Interval

- Optional.
- Specify a detection interval under global configuration mode.

Configuring Maximum Detection Times

- Optional.
- Specify the maximum detection times under global configuration mode.

Configuring Detection under Port

- Mandatory.
- Configure unidirectional RLDP detection, bidirectional RLDP detection or downlink loop detection under interface configuration mode, and specify failure treatment.

Restoring All Failed Ports

- Optional.
- Enable this function under privileged mode to restore all failed ports and resume detection.

Verification

- Display the information of global RLDP, port and neighbor.

Related Commands

Enabling Global RLDP Detection

Command	**rldp enable**
Parameter Description	N/A
Command Mode	Global configuration mode

Usage Guide	Enable global RLDP detection.

Enabling RLDP Detection on Interface

Command	**rldp port { unidirection-detect | bidirection-detect | loop-detect } { warning | shutdown-svi | shutdown-port | block }**
Parameter Description	**unidirection-detect**: Indicates unidirectional link detection. **bidirection-detect**: Indicates bidirectional forwarding detection. **loop-detect**: Indicates downlink loop detection. **warning**: Indicate the failure treatment is warning. **shutdown-svi**: Indicate the failure treatment is closing the SVI that the interface is on. **shutdown-port**: Indicates the failure treatment is port violation. **block**: Indicates the failure treatment is disabling learning and forwarding of a port.
Command Mode	Interface configuration mode
Usage Guide	The interfaces include layer-2 switch ports, layer-3 routed ports, layer-2 AP member ports, and layer-3 AP member ports. Ports on which RLDP is enabled to handle downlink loop failures are random. For example, RLDP downlink loop detection is configured on both downlink ports A and B, and the configured failure handling mode of port A is **warning** while that of port B is **shutdown-port**. When there is a downlink loop between port A and port B, port A may detect the downlink loop failure prior to port B. After port A completes failure handling according to the configuration, it no longer sends packets to detect the downlink loop status. Port B fails to detect the downlink loop failure because it does not receive a loop detection packet from port A, but the downlink loop actually persists. If a detected downlink loop needs to be actually removed in application scenarios, downlink ports in the same loop must be restricted to use a consistent loop failure handling mode and the loop failure handling mode cannot be **warning**.

Modifying Global RLDP Detection Parameters

Command	**rldp** {**detect-interval** *interval* | **detect-max** *num* | **neighbor-negotiation** }
Parameter Description	**detect-interval** *interval*: Indicates a detection interval. **detect-max** *num*: Indicates detection times. **neighbor-negotiation**: Indicates neighbor negotiation.
Command Mode	Global configuration mode
Usage Guide	Modify all RLDP parameters on all ports when necessary.

Recovering Failed Port

Command	**rldp reset**
Parameter Description	N/A
Command	Privileged mode

Mode	
Usage Guide	Recover all failed ports to initialized state and resume detection.

Displaying RLDP State Information

Command	**show rldp** [**interface** *interface-name*]
Parameter Description	*interface-name*: Indicates the interface to display information of.
Command Mode	Privileged mode, global configuration mode, or interface configuration mode
Usage Guide	Display RLDP state information.

Configuration Example

Configuring RLDP Loop Detection on Wireless APs

Scenario Figure 9-5	As shown in the following figure, a large number of APs exist in the wireless AP scenario. If the RLDP loop detection function is configured and modified on APs one by one, the workload is heavy. The RLDP loop detection configurations can be pushed from the AC device to all online APs (or an independent AP). Configuration Steps	● Log in to the AC device and enter the AP configuration mode. ● Enable the RLDP loop detection function on the wired ports of the corresponding AP. ● Enable the RLDP function on corresponding APs in global configuration mode. ● On corresponding APs, configure the recovery time for the RLDP violated port.
A	`A#configure terminal` `A(config)#ap-config all` `A(config-ap)#exec-cmd mode "int gi 0/1" cmd "rldp port loop-detect shutdown-port"` `A(config-ap)#exec-cmd mode configure cmd "rldp enable"` `A(config-ap)#exec-cmd mode configure cmd "errdisable recovery interval 600"`
Verification	● On the AC device, check the RLDP loop detection configurations.

A	`A# show run` `!` `ap-config all` ` exec-cmd mode "int gi 0/1" cmd "rldp port loop-detect shutdown-port"` ` exec-cmd mode configure cmd "rldp enable"` ` exec-cmd mode configure cmd "errdisable recovery interval 600"` `!`

Common Errors

- When the **exec-cmd** command is executed for interface configuration, the input of the corresponding AP wired port is incorrect.
- When the RLDP loop detection configurations are modified, the **no exec-cmd** command is not executed to delete the original configurations or the **exec-cmd** command is not re-executed to cancel the configurations.

9.5 Monitoring

Displaying

Description	Command
Displays RLDP state.	**show rldp** [**interface** *interface-name*]

10 Configuring LLDP

10.1 Overview

The Link Layer Discovery Protocol (LLDP), defined in the IEEE 802.1AB standard, is used to discover the topology and identify topological changes. LLDP encapsulates local information of a device into LLDP data units (LLDPDUs) in the type/length/value (TLV) format and then sends the LLDPDUs to neighbors. It also stores LLDPDUs from neighbors in the management information base (MIB) to be accessed by the network management system (NMS).

With LLDP, the NMS can learn about topology, for example, which ports of a device are connected to other devices and whether the rates and duplex modes at both ends of a link are consistent. Administrators can quickly locate and rectify a fault based on the information.

Protocols and Standards

- IEEE 802.1AB 2005: Station and Media Access Control Connectivity Discovery
- ANSI/TIA-1057: Link Layer Discovery Protocol for Media Endpoint Devices

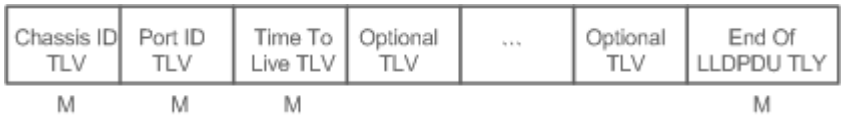
10.2 Features

Basic Concepts

LLDPDU

LLDPDU is a protocol data unit encapsulated into an LLDP packet. Each LLDPDU is a sequence of TLV structures. The TLV collection consists of three mandatory TLVs, a series of optional TLVs, and one End Of TLV. The following figure shows the format of an LLDPDU.

Figure 10-1 LLDPDU Format



In the preceding figure:

- M indicates a mandatory TLV.
- In an LLDPDU, Chassis ID TLV, Port ID TLV, Time To Live TLV, and End Of LLDPDU TLV are mandatory and TLVs of other TLVs are optional.

LLDP Encapsulation Format

LLDP packets can be encapsulated in two formats: Ethernet II and Subnetwork Access Protocols (SNAP).

The following figure shows the format of LLDP packets encapsulated in the Ethernet II format.

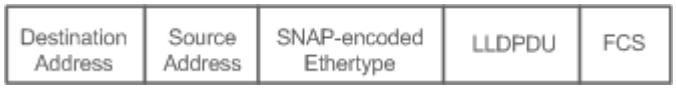
Figure 10-2 Ethernet II Format

In the preceding figure:

- Destination Address: Indicates the destination MAC address, which is the LLDP multicast address 01-80-C2-00-00-0E.
- Source Address: Indicates the source MAC address, which is the port MAC address.
- Ethertype: Indicates the Ethernet type, which is 0x88CC.
- LLDPDU: Indicates the LLDP protocol data unit.
- FCS: Indicates the frame check sequence.

Figure 1-5 shows the format of LLDP packets encapsulated in the SNAP format.

Figure 10-3 SNAP Format



In the preceding figure:

- Destination Address: Indicates the destination MAC address, which is the LLDP multicast address 01-80-C2-00-00-0E.
- Source Address: Indicates the source MAC address, which is the port MAC address.
- SNAP-encoded Ethertype: Indicates the Ethernet type of the SNMP encapsulation, which is AA-AA-03-00-00-00-88-CC.
- LLDPDU: Indicates the LLDP protocol data unit.
- FCS: Indicates the frame check sequence.

TLV

TLVs encapsulated into an LLDPDU can be classified into two types:

- Basic management TLVs
- Organizationally specific TLVs

Basic management TLVs are a collection of basic TLVs used for network management. Organizationally specific TLVs are defined by standard organizations and other institutions, for example, the IEEE 802.1 organization and IEEE 802.3 organization define their own TLV collections.

1. Basic management TLVs

The basic management TLV collection consists of two types of TLVs: mandatory TLVs and optional TLVs. A mandatory TLV must be contained in an LLDPDU for advertisement and an optional TLV is contained selectively.

The following table describes basic management TLVs.

TLV Type	Description	Mandatory/Optional
End Of LLDPDU TLV	Indicates the end of an LLDPDU, occupying two bytes.	Mandatory

Chassis ID TLV	Identifies a device with a MAC address.	Mandatory
Port ID TLV	Identifies a port sending LLDPDUs.	Fixed
Time To Live TLV	Indicates the time to live (TTL) of local information on a neighbor. When a device receives a TLV containing TTL 0, it deletes the neighbor information.	Mandatory
Port Description TLV	Indicates the descriptor of the port sending LLDPDUs.	Optional
System Name TLV	Describes the device name.	Optional
System Description TLV	Indicates the device description, including the hardware version, software version, and operating system information.	Optional
System Capabilities TLV	Describes main functions of the device, such as the bridge, routing, and relay functions.	Optional
Management Address TLV	Indicates the management address, which contains the interface ID and object identifier (OID).	Optional

2. Organizationally specific TLVs

Different organizations, such as the IEEE 802.1, IEEE 802.3, IETF and device suppliers, define specific TLVs to advertise specific information about devices. The organizationally unique identifier (OUI) field in a TLV is used to distinguish different organizations.

- Organizationally specific TLVs are optional and are advertised in an LLDPDU selectively. Currently, there are three types of common organizationally specific TLVs: IEEE 802.1 organizationally specific TLVs, IEEE 802.3 organizationally specific TLVs, and LLDP-MED TLVs.

The following table describes IEEE 802.1 organizationally specific TLVs.

TLV Type	Description
Port VLAN ID TLV	Indicates the VLAN identifier of a port.
Port And Protocol VLAN ID TLV	Indicates the protocol VLAN identifier of a port.
VLAN Name TLV	Indicates the VLAN name of a port.
Protocol Identity TLV	Indicates the protocol type supported by a port.

- IEEE 802.3 organizationally specific TLVs

The following table describes IEEE 802.3 organizationally specific TLVs.

TLV Type	Description
MAC/PHY Configuration//Status TLV	Indicates the rate and duplex mode of a port, and whether to support and enable auto-negotiation.
Power Via MDI TLV	Indicates the power supply capacity of a port.
Link Aggregation TLV	Indicates the link aggregation capacity of a port and the current aggregation state.
Maximum Frame Size TLV	Indicates the maximum size of the frame transmitted by a port.

- LLDP-MED TLV

LLDP-MED is an extension to LLDP based on IEEE 802.1AB LLDP. It enables users to conveniently deploy the Voice Over IP (VoIP) network and detect faults. It provides applications including the network configuration policies, device discovery, PoE management, and inventory management, meeting requirements for low cost, effective management, and easy deployment.

The following table describes LLDP-MED TLVs.

TLV Type	Description
LLDP-MED Capabilities TLV	Indicates the type of the LLDP-MED TLV encapsulated into an LLDPDU and device type (network connectivity device or endpoint device), and whether to support LLDP-MED,.
Network Policy TLV	Advertises the port VLAN configuration, supported application type (such as voice or video services), and Layer-2 priority information.
Location Identification TLV	Locates and identifies an endpoint device.
Extended Power-via-MDI TLV	Provides more advanced power supply management.
Inventory – Hardware Revision TLV	Indicates hardware version of a MED device.
Inventory – Firmware Revision TLV	Indicates the firmware version of the MED device.
Inventory – Software Revision TLV	Indicates the software version of the MED device.
Inventory – Serial Number TLV	Indicates the serial number of the MED device.
Inventory – Manufacturer Name TLV	Indicates the name of the manufacturer of the MED device.
Inventory – Model Name TLV	Indicates the module name of the MED device.
Inventory – Asset ID TLV	Indicates the asset identifier of the MED device, used for inventory management and asset tracking.

Overview

Feature	Description
LLDP Work Mode	Configures the mode of transmitting and receiving LLDP packets.
LLDP Transmission Mechanism	Enables directly connected LLDP-compliant devices to send LLDP packets to the peer.
LLDP Reception Mechanism	Enables directly connected LLDP-compliant devices to receive LLDP packets from the peer.

10.2.1 LLDP Work Mode

Configure the LLDP work mode so as to specify the LLDP packet transmission and reception mode.

Working Principle

LLDP provides three work modes:

- TxRx: Transmits and receives LLDPDUs.
- Rx Only: Only receives LLDPDUs.
- Tx Only: Only transmits LLDPDUs.

When the LLDP work mode is changed, the port initializes the protocol state machine. You can set a port initialization delay to prevent repeated initialization of a port due to frequent changes of the LLDP work mode.

Related Configuration

Configuring the LLDP Work Mode

The default LLDP work mode is TxRx.

You can run the **lldp mode** command to configure the LLDP work mode.

If the work mode is set to TxRx, the device can both transmit and receive LLDP packets. If the work mode is set to Rx Only, the device can only receive LLDP packets. If the work mode is set to Tx Only, the device can only transmit LLDP packets. If the work mode is disabled, the device cannot transmit or receive LLDP packets.

10.2.2 LLDP Transmission Mechanism

LLDP packets inform peers of their neighbors. When the LLDP transmission mode is cancelled or disabled, LLDP packets cannot be transmitted to neighbors.

Working Principle

LLDP periodically transmits LLDP packets when working in TxRx or Tx Only mode. When information about the local device changes, LLDP immediately transmits LLDP packets. You can configure a delay time to avoid frequent transmission of LLDP packets caused by frequent changes of local information.
LLDP provides two types of packets:

- Standard LLDP packet, which contains management and configuration information about the local device.
- Shutdown packet: When the LLDP work mode is disabled or the port is shut down, LLDP Shutdown packets will be transmitted. A Shutdown packet consists of the Chassis ID TLV, Port ID TLV, Time To Live TLV, and End OF LLDP TLV. TTL in the Time to Live TLV is 0. When a device receives an LLDP Shutdown packet, it considers that the neighbor information is invalid and immediately deletes it.

When the LLDP work mode is changed from disabled or Rx to TxRx or Tx, or when LLDP discovers a new neighbor (that is, a device receives a new LLDP packet and the neighbor information is not stored locally), the fast transmission mechanism is started so that the neighbor quickly learns the device information. The fast transmission mechanism enables a device to transmit multiple LLDP packets at an interval of 1 second.

Related Configuration

Configuring the LLDP Work Mode

The default work mode is TxRx.

Run the **lldp mode txrx** or **lldp mode tx** command to enable the LLDP packet transmission function. Run the **lldp mode rx** or **no lldp mode** command to disable the LLDP packet transmission function.

In order to enable LLDP packet reception, set the work mode to TxRx or Rx Only. If the work mode is set to Rx Only, the device can only receive LLDP packets.

Configuring the LLDP Transmission Delay

The default LLDP transmission delay is 2 seconds.

Run the **lldp timer tx-delay** command to change the LLDP transmission delay.

If the delay is set to a very small value, the frequent change of local information will cause frequent transmission of LLDP packets. If the delay is set to a very large value, no LLDP packet may be transmitted even if local information is changed.

Configuring the LLDP Transmission Interval

The default LLDP transmission interval is 30 seconds.

Run the **lldp timer tx-interval** command to change the LLDP transmission interval.

If the interval is set to a very small value, LLDP packets may be transmitted frequently. If the interval is set to a very large value, the peer may not discover the local device in time.

Configuring the TLVs to Be Advertised

By default, an interface is allowed to advertise TLVs of all types except Location Identification TLV.

Run the **lldp tlv-enable** command to change the TLVs to be advertised.

Configuring the LLDP Fast Transmission Count

By default, three LLDP packets are fast transmitted.

Run the **lldp fast-count** command to change the number of LLDP packets that are fast transmitted.

10.2.3 LLDP Reception Mechanism

A device can discover the neighbor and determine whether to age the neighbor information according to received LLDP packets.

Working Principle

A device can receive LLDP packets when working in TxRx or Rx Only mode. After receiving an LLDP packet, a device conducts validity check. After the packet passes the check, the device checks whether the packet contains information about a new neighbor or about an existing neighbor and stores the neighbor information locally. The device sets the TTL of neighbor information according to the value of TTL TLV in the packet. If the value of TTL TLV is 0, the neighbor information is aged immediately.

Related Configuration

Configuring the LLDP Work Mode

The default LLDP work mode is TxRx.

Run the **lldp mode txrx** or **lldp mode rx** command to enable the LLDP packet reception function. Run the **lldp mode tx** or **no lldp mode** command to disable the LLDP packet reception function.

In order to enable LLDP packet reception, set the work mode to TxRx or Rx Only. If the work mode is set to Tx Only, the device can only transmit LLDP packets.

10.3 Configuration

Configuration	Description and Command	
Configuring the LLDP Function	(Optional) It is used to enable or disable the LLDP function in global or interface configuration mode.	
	lldp enable	Enables the LLDP function.
	no lldp enable	Disables the LLDP function.
Configuring the LLDP Work Mode	(Optional) It is used to configure the LLDP work mode.	
	lldp mode {rx | tx | txrx }	Configures the LLDP work mode.
	no lldp mode	Shuts down the LLDP work mode.
Configuring the TLVs to Be Advertised	(Optional) It is used to configure the TLVs to be advertised.	
	lldp tlv-enable	Configures the TLVs to be advertised.
	no lldp tlv-enable	Cancels TLVs.
Configures the Management Address to Be Advertised	(Optional) It is used to configure the management address to be advertised in LLDP packets.	
	lldp management-address-tlv [*ip-address*]	Configures the management address to be advertised in LLDP packets.
	no lldp management-address-tlv	Cancels the management address.
Configuring the LLDP Fast Transmission Count	(Optional) It is used to configure the number of LLDP packets that are fast transmitted.	
	lldp fast-count *value*	Configures the LLDP fast transmission count.
	no lldp fast-count	Restores the default LLDP fast transmission count.
Configuring the TTL Multiplier and Transmission Interval	(Optional) It is used to configure the TTL multiplier and transmission interval.	
	lldp hold-multiplier *value*	Configures the TTL multiplier.
	no lldp hold-multiplier	Restores the default TTL multiplier.
	lldp timer tx-interval *seconds*	Configures the transmission interval.
	no lldp timer tx-interval	Restores the default transmission interval.
Configuring the Transmission Delay	(Optional) It is used to configure the delay time for LLDP packet transmission.	
	lldp timer tx-delay *seconds*	Configures the transmission delay.
	no lldp timer tx-delay	Restores the default transmission delay.

Configuration	Description and Command	
Configuring the Initialization Delay	(Optional) It is used to configure the delay time for LLDP to initialize on any interface.	
	lldp timer reinit-delay *seconds*	Configures the initialization delay.
	no lldp timer reinit-delay	Restores the default initialization delay.
Configuring the LLDP Trap Function	(Optional) It is used to configure the LLDP Trap function.	
	lldp notification remote-change enable	Enables the LLDP Trap function.
	no lldp notification remote-change enable	Disables the LLDP Trap function.
	lldp timer notification-interval	Configures the LLDP Trap transmission interval.
	no lldp timer notification-interval	Restores the default LLDP Trap transmission interval.
Configuring the LLDP Error Detection Function	(Optional) It is used to configure the LLDP error detection function.	
	lldp error-detect	Enables the LLDP error detection function.
	no lldp error-detect	Disables the LLDP error detection function.
Configuring the LLDP Encapsulation Format	(Optional) It is used to configure the LLDP encapsulation format.	
	lldp encapsulation snap	Sets the LLDP encapsulation format to SNAP.
	no lldp encapsulation snap	Sets the LLDP encapsulation format to Ethernet II.
Configuring the LLDP Network Policy	(Optional) It is used to configure the LLDP Network Policy.	
	lldp network-policy profile *profile-num*	Configures an LLDP Network Policy.
	no lldp network-policy profile *profile-num*	Deletes an LLDP Network Policy.
Configuring the Civic Address	(Optional) It is used to configure the civic address of a device.	
	{ **country | state | county | city | division | neighborhood | street-group | leading-street-dir | trailing-street-suffix | street-suffix | number | street-number-suffix | landmark | additional-location-information | name | postal-code | building | unit | floor | room | type-of-place | postal-community-name | post-office-box | additional-code** } *ca-word*	Configures the civic address of a device.

Configuration	Description and Command	
	no { **country | state | county | city | division | neighborhood | street-group | leading-street-dir | trailing-street-suffix | street-suffix | number | street-number-suffix | landmark | additional-location-information | name | postal-code | building | unit | floor | room | type-of-place | postal-community-name | post-office-box | additional-code** } *ca-word*	Deletes civic address of a device.
Configuring the Emergency Telephone Number	⚠ (Optional) It is used to configure the emergency telephone number of a device.	
	lldp location elin identifier *id* **elin-location** *tel-number*	Configures the emergency telephone number of a device.
	no lldp location elin identifier *id*	Deletes the emergency telephone number of a device.

10.3.1 Configuring the LLDP Function

Configuration Effect

- Enable or disable the LLDP function.

Notes

- To make the LLDP function take effect on an interface, you need to enable the LLDP function globally and on the interface.

Configuration Steps

- Optional.
- Configure the LLDP function in global or interface configuration mode.

Verification

Display LLDP status

- Check whether the LLDP function is enabled in global configuration mode.
- Check whether the LLDP function is enabled in interface configuration mode.

Related Commands

↘ Enabling the LLDP Function

Command	**lldp enable**
Parameter De	N/A

scription	
Command Mode	Global configuration mode/Interface configuration mode
Usage Guide	The LLDP function takes effect on an interface only after it is enabled in global configuration mode and interface configuration mode.

Disabling the LLDP Function

Command	**no lldp enable**
Parameter De scription	N/A
Command Mode	Global configuration mode/Interface configuration mode
Usage Guide	N/A

Configuration Example

Disabling the LLDP Function

Configuration Steps	Disable the LLDP function in global configuration mode.
	`Ruijie(config)#no lldp enable`
Verification	Display global LLDP status.
	`Ruijie(config)#show lldp status` `Global status of LLDP: Disable`

Common Errors

- If the LLDP function is enabled on an interface but disabled in global configuration mode, the LLDP function does not take effect on the interface.
- A port can learn a maximum of five neighbors.
- If a neighbor does not support LLDP but it is connected to an LLDP-supported device, a port may learn information about the device that is not directly connected to the port because the neighbor may forward LLDP packets.

10.3.2 Configuring the LLDP Work Mode

Configuration Effect

- If you set the LLDP work mode to TxRx, the interface can transmit and receive packets.
- If you set the LLDP work mode to Tx, the interface can only transmit packets but cannot receive packets.
- If you set the LLDP work mode to Rx, the interface can only receive packets but cannot transmit packets.

- If you disable the LLDP work mode, the interface can neither receive nor transmit packets.

Notes

- LLDP runs on physical ports (AP member ports for AP ports). Stacked ports and VSL ports do not support LLDP.

Configuration Steps

- Optional.
- Set the LLDP work mode to Tx or Rx as required.

Verification

Display LLDP status information on an interface

Check whether the configuration takes effect.

Related Commands

Configuring the LLDP Work Mode

Command	**lldp mode** { **rx** | **tx** | **txrx** }
Parameter Description	**rx**: Only receives LLDPDUs. **tx**: Only transmits LLDPDUs. **txrx**: Transmits and receives LLDPDUs.
Command Mode	Interface configuration mode
Usage Guide	To make LLDP take effect on an interface, make sure to enable LLDP globally and set the LLDP work mode on the interface to Tx, Rx or TxRx.

Disabling the LLDP Work Mode

Command	**no lldp mode**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	After the LLDP work mode on an interface is disabled, the interface does not transmit or receive LLDP packets.

Configuration Example

Configuring the LLDP Work Mode

Configuration Steps	Set the LLDP work mode to Tx in interface configuration mode.
	`Ruijie(config)#interface gigabitethernet 0/1`

	Ruijie(config-if-GigabitEthernet 0/1)#lldp mode tx
Verification	Display LLDP status information on the interface.
	Ruijie(config-if-GigabitEthernet 0/1)#show lldp status interface gigabitethernet 0/1 Port [GigabitEthernet 0/1] Port status of LLDP : Enable Port state : UP Port encapsulation : Ethernet II Operational mode : TxOnly Notification enable : NO Error detect enable : YES Number of neighbors : 0 Number of MED neighbors : 0

10.3.3 Configuring the TLVs to Be Advertised

Configuration Effect

- Configure the type of TLVs to be advertised to specify the LLDPDUs in LLDP packets.

Notes

- If you configure the **all** parameter for the basic management TLVs, IEEE 802.1 organizationally specific TLVs, and IEEE 802.3 organizationally specific TLVs, all optional TLVs of these types are advertised.
- If you configure the **all** parameter for the LLDP-MED TLVs, all LLDP-MED TLVs except Location Identification TLV are advertised.
- If you want to configure the LLDP-MED Capability TLV, configure the LLDP 802.3 MAC/PHY TLV first; If you want to cancel the LLDP 802.3 MAC/PHY TLV, cancel the LLDP-MED Capability TLV first.
- If you want to configure LLDP-MED TLVs, configure the LLDP-MED Capability TLV before configuring other types of LLDP-MED TLVs. If you want to cancel LLDP-MED TLVs, cancel the LLDP-MED Capability TLV before canceling other types of LLDP-MED TLVs If a device is connected to an IP-Phone that supports LLDP-MED, you can configure the Network Policy TLV to push policy configuration to the IP-Phone.
- If a device supports the DCBX function by default, ports of the device are not allowed to advertise IEEE 802.3 organizationally specific TLVs and LLDP-MED TLVs by default.

Configuration Steps

- Optional.
- Configure the type of TLVs to be advertised on an interface.

Verification

Display the configuration of TLVs to be advertised on an interface

Check whether the configuration takes effect.

Related Commands

Configuring TLVs to Be Advertised

Command	**lldp tlv-enable** { **basic-tlv** { **all | port-description | system-capability | system-description | system-name** } **|dot1-tlv** { **all | port-vlan-id | protocol-vlan-id** [*vlan-id*] | **vlan-name** [*vlan-id*] } **|dot3-tlv** { **all | link-aggregation | mac-physic | max-frame-size | power } | med-tlv { all | capability | inventory | location** { **civic-location | elin** } **identifier** *id* **| network-policy profile** [*profile-num*] **| power-over-ethernet** } }

Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuring TLVs to Be Advertised

Configuration	Cancel the advertisement of the IEEE 802.1 organizationally specific Port And Protocol VLAN ID TLV.

Steps	
	Ruijie(config)#interface gigabitethernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)#no lldp tlv-enable dot1-tlv protocol-vlan-id
Verification	Display LLDP TLV configuration in interface configuration mode.
	Ruijie(config-if-GigabitEthernet 0/1)#show lldp tlv-config interface gigabitethernet 0/1 LLDP tlv-config of port [GigabitEthernet 0/1] NAME STATUS DEFAULT ------------------------------ ------ ------- Basic optional TLV: Port Description TLV YES YES System Name TLV YES YES System Description TLV YES YES System Capabilities TLV YES YES Management Address TLV YES YES IEEE 802.1 extend TLV: Port VLAN ID TLV YES YES Port And Protocol VLAN ID TLV NO YES VLAN Name TLV YES YES IEEE 802.3 extend TLV: MAC-Physic TLV YES YES Power via MDI TLV YES YES Link Aggregation TLV YES YES Maximum Frame Size TLV YES YES LLDP-MED extend TLV: Capabilities TLV YES YES Network Policy TLV YES YES Location Identification TLV NO NO Extended Power via MDI TLV YES YES

	Inventory TLV YES YES

10.3.4 Configures the Management Address to Be Advertised

Configuration Effect

- Configure the management address to be advertised in LLDP packets in interface configuration mode.
- After the management address to be advertised is cancelled, the management address in LLDP packets is subject to the default settings.

Notes

- LLDP runs on physical ports (AP member ports for AP ports). Stacked ports and VSL ports do not support LLDP.

Configuration Steps

- Optional.
- Configure the management address to be advertised in LLDP packets in interface configuration mode.

Verification

Display LLDP information on a local interface

- Check whether the configuration takes effect.

Related Commands

Configuring the Management Address to Be Advertised

Command	**lldp management-address-tlv** [*ip-address*]
Parameter Description	*ip-address*: Indicates the management address to be advertised in an LLDP packet.
Command Mode	Interface configuration mode
Usage Guide	A management address is advertised through LLDP packets by default. The management address is the IPv4 address of the minimum VLAN supported by the port. If no IPv4 address is configured for the VLAN, LLDP keeps searching for the qualified IP address. If no IPv4 address is found, LLDP searches for the IPv6 address of the minimum VLAN supported by the port. If no IPv6 address is found, the loopback address 127.0.0.1 is used as the management address.

Canceling the Management Address

Command	**no lldp management-address-tlv**
Parameter Description	N/A
Command	Interface configuration mode

Mode	
Usage Guide	A management address is advertised through LLDP packets by default. The management address is the IPv4 address of the minimum VLAN supported by the port. If no IPv4 address is configured for the VLAN, LLDP keeps searching for the qualified IP address. If no IPv4 address is found, LLDP searches for the IPv6 address of the minimum VLAN supported by the port. If no IPv6 address is found, the loopback address 127.0.0.1 is used as the management address.

Configuration Example

Configuring the Management Address to Be Advertised

Configuration Steps	Set the management address to 192.168.1.1 on an interface.
	Ruijie(config)#interface gigabitethernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)#lldp management-address-tlv 192.168.1.1
Verification	Display configuration on the interface.
	Ruijie(config-if-GigabitEthernet 0/1)#show lldp local-information interface GigabitEthernet 0/1 Lldp local-information of port [GigabitEthernet 0/1] Port ID type : Interface name Port id : GigabitEthernet 0/1 Port description : GigabitEthernet 0/1 Management address subtype : ipv4 Management address : 192.168.1.1 Interface numbering subtype : ifIndex Interface number : 1 Object identifier : 802.1 organizationally information Port VLAN ID : 1 Port and protocol VLAN ID(PPVID) : 1 PPVID Supported : YES PPVID Enabled : NO VLAN name of VLAN 1 : VLAN0001

10.3.5 Configuring the LLDP Fast Transmission Count

Configuration Effect

- Configure the number of LLDP packets that are fast transmitted.

Configuration Steps

- Optional.
- Configure the number of LLDP packets that are fast transmitted in global configuration mode.

Verification

Displaying the global LLDP status information

- Check whether the configuration takes effect.

Related Commands

Configuring the LLDP Fast Transmission Count

Command	**lldp fast-count** *value*
Parameter Description	*value*: Indicates the number of LLDP packets that are fast transmitted. The value ranges from 1 to 10. The default value is 3.
Command Mode	Global configuration mode
Usage Guide	N/A

Restoring the Default LLDP Fast Transmission Count

Command	**no lldp fast-count**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the LLDP Fast Transmission Count

Configuration Steps	Set the LLDP fast transmission count to 5 in global configuration mode.
	`Ruijie(config)#lldp fast-count 5`
Verification	Display the global LLDP status information.
	`Ruijie(config)#show lldp status` `Global status of LLDP : Enable` `Neighbor information last changed time :` `Transmit interval : 30s` `Hold multiplier : 4` `Reinit delay : 2s` `Transmit delay : 2s` `Notification interval : 5s` `Fast start counts : 5`

10.3.6 Configuring the TTL Multiplier and Transmission Interval

Configuration Effect

- Configure the TTL multiplier.
- Configure the LLDP packet transmission interval.

Notes

- Indicates the LLDP packet transmission interval. The value ranges from 1 to 32,768, which is larger than the standard MIB range (5 to 32,768). Thus, it can meet more requirements.

Configuration Steps

- Optional.
- Perform the configuration in global configuration mode.

Verification

Display LLDP status information on an interface

Check whether the configuration takes effect.

Related Commands

Configuring the TTL Multiplier

Command	**lldp hold-multiplier** *value*
Parameter Description	*value*: Indicates the TLL multiplier. The value ranges from 2 to 10. The default value is 4.
Command Mode	Global configuration mode
Usage Guide	In an LLDP packet. the value of Time To Live TLV is calculated based on the following formula: Time to Live TLV= TTL multiplier x Packet transmission interval + 1. Therefore, you can modify the Time to Live TLV in LLDP packets by configuring the TTL multiplier.

Restoring the Default TTL Multiplier

Command	**no lldp hold-multiplier**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	In an LLDP packet, the value of Time To Live TLV is calculated based on the following formula: Time to Live TLV = TTL multiplier x Packet transmission interval + 1. Therefore, you can modify the Time to Live TLV in LLDP packets by configuring the TTL multiplier.

Configuring the Transmission Interval

Command	**lldp timer tx-interval** *seconds*
Parameter De	*seconds*: Indicates the LLDP packet transmission interval. The value ranges from 1 to 32,768.

scription	
Command Mode	Global configuration mode
Usage Guide	N/A

Restoring the Default Transmission Interval

Command	**no lldp timer tx-interval**
Parameter De scription	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the TTL Multiplier and Transmission Interval

Configuration Steps	Set the TTL multiplier to 3 and the transmission interval to 20 seconds. The TTL of local device information on neighbors is 61 seconds.
	`Ruijie(config)#lldp hold-multiplier 3` `Ruijie(config)#lldp timer tx-interval 20`
Verification	Display the global LLDP status information.
	`Ruijie(config)#lldp hold-multiplier 3` `Ruijie(config)#lldp timer tx-interval 20` `Ruijie(config)#show lldp status` `Global status of LLDP : Enable` `Neighbor information last changed time :` `Transmit interval : 20s` `Hold multiplier : 3` `Reinit delay : 2s` `Transmit delay : 2s` `Notification interval : 5s` `Fast start counts : 3`

10.3.7 Configuring the Transmission Delay

Configuration Effect

- Configure the delay time for LLDP packet transmission.

Configuration Steps

- Optional.
- Perform the configuration in global configuration mode.

Verification

Displaying the global LLDP status information

Check whether the configuration takes effect.

Related Commands

Configuring the Transmission Delay

Command	**lldp timer tx-delay** *seconds*
Parameter Description	*seconds*: Indicates the transmission delay. The value ranges from 1 to 8,192.
Command Mode	Global configuration mode
Usage Guide	When local information of a device changes, the device immediately transmits LLDP packets to its neighbors. Configure the transmission delay to prevent frequent transmission of LLDP packets caused by frequent changes of local information.

Restoring the Default Transmission Delay

Command	**no lldp timer tx-delay**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When local information of a device changes, the device immediately transmits LLDP packets to its neighbors. Configure the transmission delay to prevent frequent transmission of LLDP packets caused by frequent changes of local information.

Configuration Example

Configuring the Transmission Delay

Configuration Steps	Set the transmission delay to 3 seconds.
	`Ruijie(config)#lldp timer tx-delay 3`
Verification	Display the global LLDP status information.

```
Ruijie(config)#show lldp status
Global status of LLDP                 : Enable
Neighbor information last changed time :
Transmit interval                     : 30s
Hold multiplier                       : 4
Reinit delay                          : 2s
Transmit delay                        : 3s
Notification interval                 : 5s
Fast start counts                     : 3
```

10.3.8 Configuring the Initialization Delay

Configuration Effect

- Configure the delay time for LLDP to initialize on any interface.

Configuration Steps

- Optional.
- Configure the delay time for LLDP to initialize on any interface.

Verification

Display the global LLDP status information

Check whether the configuration takes effect.

Related Commands

Configuring the Initialization Delay

Command	**lldp timer reinit-delay** *seconds*
Parameter Description	*seconds*: Indicates the initialization delay . The value ranges from 1 to 10 seconds.
Command Mode	Global configuration mode
Usage Guide	Configure the initialization delay to prevent frequent initialization of the state machine caused by frequent changes of the port work mode.

Restoring the Default Initialization Delay

Command	**no lldp timer reinit-delay**
Parameter De	N/A

scription	
Command Mode	Global configuration mode
Usage Guide	Configure the initialization delay to prevent frequent initialization of the state machine caused by frequent changes of the port work mode.

Configuration Example

Configuring the Initialization Delay

Configuration Steps	Set the initialization delay to 3 seconds.
	`Ruijie(config)#lldp timer reinit-delay 3`
Verification	Display the global LLDP status information.
	`Ruijie(config)#show lldp status` `Global status of LLDP : Enable` `Neighbor information last changed time :` `Transmit interval : 30s` `Hold multiplier : 4` `Reinit delay : 3s` `Transmit delay : 2s` `Notification interval : 5s` `Fast start counts : 3`

10.3.9 Configuring the LLDP Trap Function

Configuration Effect

- Configure the interval for transmitting LLDP Trap messages.

Configuration Steps

Enabling the LLDP Trap Function

- Optional.
- Perform the configuration in interface configuration mode.

Configuring the LLDP Trap Transmission Interval

- Optional.
- Perform the configuration in global configuration mode.

Verification

Display LLDP status information

Check whether the LLDP Trap function is enabled.

Check whether the interval configuration takes effect.

Related Commands

Enabling the LLDP Trap Function

Command	**lldp notification remote-change enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	The LLDP Trap function enables a device to send its local LLDP information (such as neighbor discovery and communication link fault) to the NMS server so that administrators learn about the network performance

Disabling the LLDP Trap Function

Command	**no lldp notification remote-change enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	The LLDP Trap function enables a device to send its local LLDP information (such as neighbor discovery and communication link fault) to the NMS server so that administrators learn about the network performance.

Configuring the LLDP Trap Transmission Interval

Command	**lldp timer notification-interval** *seconds*
Parameter Description	*seconds*: Indicates the interval for transmitting LLDP Trap messages. The value ranges from 5 to 3,600 seconds. The default value is 5 seconds.
Command Mode	Global configuration mode
Usage Guide	Configure the LLDP Trap transmission interval to prevent frequent transmission of LLDP Trap messages. LLDP changes detected within this interval will be transmitted to the NMS server.

Restoring the LLDP Trap Transmission Interval

Command	**no lldp timer notification-interval**
Parameter Description	N/A
Command	Global configuration mode

Mode	
Usage Guide	Configure the LLDP Trap transmission interval to prevent frequent transmission of LLDP Trap messages. LLDP changes detected within this interval will be transmitted to the NMS server.

Configuration Example

↘ Enabling the LLDP Trap Function and Configuring the LLDP Trap Transmission Interval

Configuration Steps	Enable the LLDP Trap function and set the LLDP Trap transmission interval to 10 seconds.
	Ruijie(config)#lldp timer notification-interval 10 Ruijie(config)#interface gigabitethernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)#lldp notification remote-change enable
Verification	Display LLDP status information.
	Ruijie(config-if-GigabitEthernet 0/1)#show lldp status Global status of LLDP : Enable Neighbor information last changed time : Transmit interval : 30s Hold multiplier : 4 Reinit delay : 2s Transmit delay : 2s Notification interval : 10s Fast start counts : 3 -- Port [GigabitEthernet 0/1] -- Port status of LLDP : Enable Port state : UP Port encapsulation : Ethernet II Operational mode : RxAndTx Notification enable : YES Error detect enable : YES Number of neighbors : 0 Number of MED neighbors : 0

10.3.10 Configuring the LLDP Error Detection Function

Configuration Effect

- Enable the LLDP error detection function. When LLDP detects an error, the error is logged.
- Configure the LLDP error detection function to detect VLAN configuration at both ends of a link, port status, aggregate port configuration, MTU configuration, and loops.

Notes

N/A

Configuration Steps

- Optional.
- Enable or disable the LLDP error detection function in interface configuration mode.

Verification

Display LLDP status information on an interface

Check whether the configuration takes effect.

Related Commands

Enabling the LLDP Error Detection Function

Command	lldp error-detect
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	The LLDP error detection function relies on specific TLVs in LLDP packets exchanged between devices at both ends of a link. Therefore, a device needs to advertise correct TLVs to ensure the LLDP error detection function.

Disabling the LLDP Error Detection Function

Command	no lldp error-detect
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	The LLDP error detection function relies on specific TLVs in LLDP packets exchanged between devices at both ends of a link. Therefore, a device needs to advertise correct TLVs to ensure the LLDP error detection function.

Configuration Example

Enabling the LLDP Error Detection Function

Configuration Steps	Enable the LLDP error detection function on interface GigabitEthernet 0/1.
	Ruijie(config)#interface gigabitethernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)#lldp error-detect
Verification	Display LLDP status information on the interface.
	Ruijie(config-if-GigabitEthernet 0/1)#show lldp status interface gigabitethernet 0/1 Port [GigabitEthernet 0/1] Port status of LLDP : Enable Port state : UP Port encapsulation : Ethernet II Operational mode : RxAndTx Notification enable : NO Error detect enable : YES Number of neighbors : 0 Number of MED neighbors : 0

10.3.11 Configuring the LLDP Encapsulation Format

Configuration Effect

- Configure the LLDP encapsulation format.

Configuration Steps

- Optional.
- Configure the LLDP encapsulation format on an interface.

Verification

Display LLDP status information of an interface

Check whether the configuration takes effect.

Related Commands

Setting the LLDP Encapsulation Format to SNAP

Command	**lldp encapsulation snap**
Parameter De	N/A

scription	
Command Mode	Interface configuration mode
Usage Guide	The LLDP encapsulation format configuration on a device and its neighbors must be consistent.

Restoring the Default LLDP Encapsulation Format (Ethernet II)

Command	**No lldp encapsulation snap**
Parameter De scription	N/A
Command Mode	Interface configuration mode
Usage Guide	The LLDP encapsulation format configuration on a device and its neighbors must be consistent.

Configuration Example

Setting the LLDP Encapsulation Format to SNAP

Configuration Steps	Set the LLDP encapsulation format to SNAP.
	`Ruijie(config)#interface gigabitethernet 0/1` `Ruijie(config-if-GigabitEthernet 0/1)#lldp encapsulation snap`
Verification	Display LLDP status information on the interface.
	`Ruijie(config-if-GigabitEthernet 0/1)#show lldp status interface gigabitethernet 0/1` `Port [GigabitEthernet 0/1]` `Port status of LLDP : Enable` `Port state : UP` `Port encapsulation : Snap` `Operational mode : RxAndTx` `Notification enable : NO` `Error detect enable : YES` `Number of neighbors : 0` `Number of MED neighbors : 0`

10.3.12 Configuring the LLDP Network Policy

Configuration Effect

- Configure the LLDP Network Policy.
- If a device is connected to an IP-Phone that supports LLDP-MED, you can configure the Network Policy TLV to push policy configuration to the IP-Phone, , which enables the IP-Phone to change the tag and QoS of voice streams. In addition to the LLDP Network Policy, perform the following steps on the device: 1. Enable the Voice VLAN function and add the port connected to the IP-Phone to the Voice VLAN. 2. Configure the port connected to the IP-Phone as a QoS trusted port (the trusted DSCP mode is recommended). 3. If 802.1X authentication is also enabled on the port, configure a secure channel for the packets from the Voice VLAN. If the IP-Phone does not support LLDP-MED, enable the voice VLAN function and add the MAC address of the IP-Phone to the Voice VLAN OUI list manually.
- For the configuration of the QoS trust mode, see *Configuring IP QoS*; for the configuration of the Voice VLAN, see *Configuring Voice VLAN*; for the configuration of the secure channel, see *Configuring ACL*.

Configuration Steps

- Optional.
- Configure the LLDP Network Policy.

Verification

Display the LLDP network policy configuration.

Check whether the configuration takes effect.

Related Commands

Configuring the LLDP Network Policy

Command	**lldp network-policy profile** *profile-num*
Parameter Description	*profile-num*: Indicates the ID of an LLDP Network Policy. The value ranges from 1 to 1,024.
Command Mode	Global configuration mode
Usage Guide	Run this command to enter the LLDP network policy mode after specifying a policy ID. After entering the LLDP network policy mode, run the **{ voice | voice-signaling } vlan** command to configure a specific network policy.

Deleting the LLDP Network Policy

Command	**no lldp network-policy profile** *profile-num*
Parameter Description	*profile-num*: Indicates the LLDP Network Policy ID. The value ranges from 1 to 1,024.
Command Mode	Interface configuration mode
Usage Guide	Run this command to enter the LLDP network policy mode after specifying a policy ID. After entering the LLDP network policy mode, run the **{ voice | voice-signaling } vlan** command to configure a specific network policy.

Configuration Example

Configuring the LLDP Network Policy

Configuration Steps	Set the Network Policy TLV to 1 for LLDP packets to be advertised by port GigabitEthernet 0/1 and set the VLAN ID of the Voice application to 3, CoS to 4, and DSCP to 6.
	Ruijie#config Ruijie(config)#lldp network-policy profile 1 Ruijie(config-lldp-network-policy)# voice vlan 3 cos 4 Ruijie(config-lldp-network-policy)# voice vlan 3 dscp 6 Ruijie(config-lldp-network-policy)#exit Ruijie(config)# interface gigabitethernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# lldp tlv-enable med-tlv network-policy profile 1
Verification	Display the LLDP network policy configuration on the local device.
	network-policy information: ------------------------- network policy profile :1 voice vlan 3 cos 4 voice vlan 3 dscp 6

10.3.13 Configuring the Civic Address

Configuration Effect

- Configure the civic address of a device.

Configuration Steps

- Optional.
- Perform this configuration in LLDP Civic Address configuration mode.

Verification

Display the LLDP civic address of the local device

- Check whether the configuration takes effect.

Related Commands

Configuring the Civic Address of a Device

Command	Configure the LLDP civic address. Use the **no** option to delete the address. { **country | state | county | city | division | neighborhood | street-group | leading-street-dir | trailing-street-suffix | street-suffix | number | street-number-suffix | landmark | additional-location-information | name | postal-code | building | unit | floor | room | type-of-place | postal-community-name | post-office-box | additional-code** } *ca-word*
Parameter Description	**country**: Indicates the country code, with two characters. CH indicates China. **state**: Indicates the CA type is 1. **county**: Indicates that the CA type is 2. **city**: Indicates that the CA type is 3. **division**: Indicates that the CA type is 4. **neighborhood**: Indicates that the CA type is 5. **street-group**: Indicates that the CA type is 6. **leading-street-dir**: Indicates that the CA type is 16. **trailing-street-suffix**: Indicates that the CA type is 17. **street-suffix**: Indicates that the CA type is 18. **number**: Indicates that the CA type is 19. **street-number-suffix**: Indicates that the CA type is 20. **landmark**: Indicates that the CA type is 21. **additional-location-information**: Indicates that the CA type is 22. **name**: Indicates that the CA type is 23. **postal-code**: Indicates that the CA type is 24. **building**: Indicates that the CA type is 25. **unit**: Indicates that the CA type is 26. **floor**: Indicates that the CA type is 27. **room**: Indicates that the CA type is 28. **type-of-place**: Indicates that the CA type is 29. **postal-community-name**: Indicates that the CA type is 30. **post-office-box**: Indicates that the CA type is 31. **additional-code**: Indicates that the CA type is 32. *ca-word*: Indicates the address.
Command Mode	LLDP Civic Address configuration mode
Usage Guide	After entering the LLDP Civic Address configuration mode, configure the LLDP civic address.

Deleting the Civic Address of a Device

Command	**no** { **country | state | county | city | division | neighborhood | street-group | leading-street-dir | trailing-street-suffix | street-suffix | number | street-number-suffix | landmark | additional-location-information | name | postal-code | building | unit | floor | room | type-of-place | postal-community-name | post-office-box | additional-code** }
Parameter Description	N/A

Command Mode	LLDP Civic Address configuration mode
Usage Guide	After entering the LLDP Civic Address configuration mode, configure the LLDP civic address.

Configuring the Device Type

Command	**device-type** *device-type*
Parameter Description	*device-type*: Indicates the device type. The value ranges from 0 to 2. The default value is 1. 0 indicates that the device type is DHCP server. 1 indicates that the device type is switch. 2 indicates that the device type is LLDP MED .
Command Mode	LLDP Civic Address configuration mode
Usage Guide	After entering the LLDP Civic Address configuration mode, configure the device type.

Restoring the Device Type

Command	**no device-type**
Parameter Description	N/A
Command Mode	LLDP Civic Address configuration mode
Usage Guide	After entering the LLDP Civic Address configuration mode, restore the default settings.

Configuration Example

Configuring the Civic Address of a Device

Configuration Steps	Set the address of port GigabitEthernet 0/1 as follows: set country to CH, city to Fuzhou, and postal code to 350000.
	`Ruijie#config` `Ruijie(config)#lldp location civic-location identifier 1` `Ruijie(config-lldp-civic)# country CH` `Ruijie(config-lldp-civic)# city Fuzhou` `Ruijie(config-lldp-civic)# postal-code 350000`
Verification	Display the LLDP civic address of port GigabitEthernet 0/1 1.
	`civic location information:` `---------------------------` `Identifier :1` `country :CH`

	device type :1 city :Fuzhou postal-code :350000

10.3.14 Configuring the Emergency Telephone Number

Configuration Effect

- Configure the emergency telephone number of a device.

Configuration Steps

- Optional.
- Perform this configuration in global configuration mode.

Verification

Display the emergency telephone number of the local device

- Check whether the configuration takes effect.

Related Commands

Configuring the Emergency Telephone Number of a Device

Command	**lldp location elin identifier** *id* **elin-location** *tel-number*
Parameter Description	*id*: Indicates the identifier of an emergency telephone number. The value ranges from 1 to 1,024. *tel-number*: Indicates emergency telephone number, containing 10-25 characters.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the emergency telephone number.

Deleting the Emergency Telephone Number of a Device

Command	**no lldp location elin identifier** *id*
Parameter Description	*id*: Indicates the identifier of an emergency telephone number. The value ranges from 1 to 1,024.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the Emergency Telephone Number of a Device

Configuration Steps	Set the emergency telephone number of port GigabitEthernet 0/1 to 085285555556.

	Ruijie#config Ruijie(config)#lldp location elin identifier 1 elin-location 085283671111
Verification	Display the emergency telephone number of port GigabitEthernet 0/1.
	elin location information: ------------------------- Identifier :1 elin number :085283671111

10.4 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears LLDP statistics.	**clear lldp statistics** [**interface** *interface-name*]
Clears LLDP neighbor information.	**clear lldp table** [**interface** *interface-name*]

Displaying

Description	Command
Displays LLDP information on the local device, which will be organized as TLVs and sent to neighbors.	**show lldp local-information** [**global** | **interface** interface-name]
Displays the LLDP civic address or emergency telephone number of a local device.	**show lldp location** { **civic-location | elin-location** } { **identifier** *id* **| interface** *interface-name* **| static** }
Displays LLDP information on a neighbor.	**show lldp neighbors [interface** *interface-name*] [**detail**]
Displays the LLDP network policy configuration of the local device.	**show lldp network-policy** { **profile** [*profile-num*] | **interface** *interface-name* }
Displays LLDP statistics.	**show lldp statistics** [**global | interface** *interface-name*]
Displays LLDP status information.	**show lldp status** [**interface** *interface-name*]
Displays the configuration of TLVs to be advertised by a port.	**show lldp tlv-config** [**interface** *interface-name*]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs LLDP error processing.	**debug lldp error**
Debugs LLDP event processing.	**debug lldp event**
Debugs LLDP hot backup processing.	**debug lldp ha**
Debugs the LLDP packet reception.	**debug lldp packet**
Debugs the LLDP state machine.	**debug lldp stm**

11 Configuring DLDP

11.1 Overview

The Data Link Detection Protocol (DLDP) is a protocol used to quickly detect faulty Ethernet links.

A typical Ethernet link detection mechanism detects physical link connectivity through autonegotiation at the physical layer. Such a mechanism has limitations when detecting Layer-3 data communication exceptions despite normal physical connections.

DLDP provides reliable Layer-3 link detection information. After detecting a faulty link, DLDP shuts down the logical state of Layer-3 ports to realize fast Layer-3 protocol convergence.

11.2 Applications

Application	Description
Intra-Network Segment DLDP Detection	The source IP address of the detected port and the detected IP address are in the same network segment.
Inter-Network Segment DLDP Detection	The source IP address of the detected port and the detected IP address are in different network segments.

11.2.1 Intra-Network Segment DLDP Detection

Scenario

This section describes the basic DLDP application scenario where the source IP address of the detected port and the detected IP address are in the same network segment.

In Figure 11-1, the Gi 0/1 Layer-3 port on Switch A and the Gi 0/2 Layer-3 port on Switch C are in the same network segment. To detect the Layer-3 link connectivity from Gi 0/1 to Gi 0/2, enable DLDP on Gi 0/1 or Gi 0/2.

Figure 11-1

Remarks	Device A and Device C are switches. Gi 0/1 and Gi 0/2 are Layer-3 ports in the same network segment. B is a network in the same network segment as Gi 0/1 and Gi 0/2.

Deployment

- Enable DLDP on Gi 0/1 or Gi 0/2.

11.2.2 Inter-Network Segment DLDP Detection

Scenario

This section describes the DLDP application scenario where the source IP address of the detected port and the detected IP address are in different network segments.

In Figure 11-2, the Gi 0/1 Layer-3 port on Switch A and the Gi 0/4 Layer-3 port on Switch D are in different network segments. To detect the Layer-3 link connectivity from Gi 0/1 to Gi 0/4, enable DLDP on Gi 0/1 and configure the DLDP next-hop IP address (IP address of the Gi 0/2 port on Switch B).

Figure 11-2

Remarks	Device A, Device B, and Device D are switches. Gi 0/1 and Gi 0/4 are Layer-3 ports in different network segments.

Deployment

- Enable DLDP on Gi 0/1 and configure the DLDP next-hop IP address.

11.3 Features

Basic Concepts

DLDP Detection Interval and Retransmission Times

Detection interval: Indicates the interval at which DLDP detection packets (ICMP echo) are transmitted.

Retransmission times: Indicate the maximum times DLDP detection packets can be retransmitted in the case of a DLDP detection failure.

When a network device does not receive a reply packet from the peer end within the period of the detection interval multiplied by the retransmission times, the device determines that a Layer-3 link failure occurs and shuts down the logical state of its Layer-3 port (despite the normal physical link connection). When Layer-3 link connectivity is recovered, the device restores its Layer-3 port to Up logical state.

DLDP Detection Modes

Active mode and passive mode are two DLDP detection modes.

Active mode (default): ICMP detection packets are sent actively.

Passive mode: ICMP detection packets are received passively.

DLDP Next Hop

Next hop: Indicates the next node connected to the detected IP address in inter-network segment DLDP detection.

In some cases, DLDP needs to detect IP reachability in non-directly connected network segments. You need to configure the next-hop IP address for the detected port to allow DLDP to obtain the next-hop MAC address through an ARP packet before sending a correct ICMP packet.

In this situation, you need to avoid the return of the reply packet from another link; otherwise, DLDP will misjudge that the detected port does not receive an ICMP reply.

DLDP Recovery Times

Recovery times: Indicate the times DLDP needs to receive consecutive reply packets (ICMP reply) before it can determine link failure recovery.

In some cases, link detection may be unstable. For example, a link is only intermittently pingable. In this case, DLDP repeatedly changes the link status between Up and Down, which may further destabilize the ring network.

Recovery times indicate the times DLDP needs to receive consecutive reply packets before DLDP can set the link in Down state to Up. The default recovery times are three times, indicating that the link needs to be successfully pinged three times before it is set to Up. The recovery times setting reduces link detection sensitivity but increases stability. Related parameters are adjustable according to the network condition.

DLDP Bound MAC Address

Bound MAC address: Indicates the MAC address bound to the detected IP address.

In a complex network environment, DLDP may obtain an invalid MAC address if the detected link has abnormal ARP packets transmitted (causing ARP spoofing), which will make DLDP detection abnormal.

To address this problem, you can bind the detected IP address (or next-hop IP address) to a static MAC address to avoid a DLDP failure in the case of ARP spoofing.

Overview

Feature	Description
DLDP Detection	Detects Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the Layer-3 port.
MAC Address Binding	Binds the detected IP address to the MAC address of the detected device to avoid DLDP exceptions otherwise caused by ARP spoofing.
Passive DLDP Detection	When both ends of the detected link are enabled with DLDP, you can configure one end in passive mode to save bandwidth and CPU resources.

11.3.1 DLDP Detection

DLDP detects Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the corresponding Layer-3 port.

Working Principle

After DLDP detection is enabled, DLDP sends an ARP packet to obtain the MAC address and outbound port of the detected device or the next-hop device. Then DLDP periodically sends IPv4 ICMP echo packets to the MAC address and outbound port to detect link connectivity. If DLDP does not receive an IPv4 ICMP reply packet from the detected device within a specific period, DLDP determines that the link is abnormal and sets the Layer-3 port to Down.

Related Configuration

- Enabling DLDP Detection

By default, DLDP detection is disabled on ports.

Run the **dldp** command with the detected IP address specified to enable DLDP detection.

You can configure the next-hop IP address, MAC address of the detected device, transmission interval, retransmission times, and recovery times based on the actual environment.

11.3.2 MAC Address Binding

The MAC address binding feature is used to bind the detected IP address (or next-hop IP address) to the MAC address of the detected device (or next-hop device) to avoid DLDP exceptions otherwise caused by ARP spoofing

Working Principle

You can bind the detected IP address (or next-hop IP address) to a static MAC address to avoid a DLDP failure in the case of ARP spoofing.

Related Configuration

By default, no MAC address is bound in DLDP detection.

Bind the MAC address of the detected device when you run the **dldp** command to enable DLDP detection. If the next-hop IP address is specified, bind the MAC address of the next-hop device.

After DLDP detection is enabled, DLDP sends ARP packets and ICMP packets with a fixed destination IP address and a fixed destination MAC address. If the source IP address and MAC address in the received packet do not match the bound IP address and MAC address, DLDP will not process the packet.

11.3.3 Passive DLDP Detection

When both ends of the detected link are enabled with DLDP, you can configure one end in passive mode to save bandwidth and CPU resources.

Working Principle

After the device at the local end sends an ICMP echo packet, the peer device determines link connectivity according to the packet reception time by using specific detection parameters, which are the same as those at the local end, thus saving bandwidth and CPU resources.

Related Configuration

By default, passive DLDP detection is disabled.

Run the **dldp passive** command to enable passive DLDP detection.

After passive DLDP detection is enabled, DLDP will return an ICMP reply packet upon receiving an ICMP echo packet, instead of actively sending ICMP echo packets to the peer end. If DLDP does not receive an ICMP echo packet within a specific period, it determines that the link to the peer port is abnormal.

11.4 Configuration

Configuration	Description and Command	
Enabling DLDP Detection	(Mandatory) It is used to enable DLDP detection in interface configuration mode.	
	dldp	Enables DLDP detection.
	(Mandatory) It is used to enable passive DLDP detection in interface configuration mode.	
	dldp passive	Enables passive DLDP detection.
	(Optional) It is used to configure the detection interval, retransmission times, and recovery times of DLDP detection in global configuration mode.	
	dldp interval	Modifies the DLDP parameters globally to apply the modifications to DLDP detection on all ports.
	dldp retry	
	dldp resume	

11.4.1 Enabling DLDP Detection

Configuration Effect

- Detect Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the Layer-3 port.

Notes

- DLDP supports the configuration of multiple IP addresses on a Layer-3 port. DLDP sets the port to Down when none of the IP addresses receives an ICMP reply. If one IP address resumes communication, DLDP sets the port to Up again.
- DLDP uses the first IP address of the Layer-3 port as the source IP address of detection packets.

Configuration Steps

↘ **Enabling DLDP Detection**

- Mandatory.
- When you enable DLDP detection in interface configuration mode, you can configure the next-hop IP address, MAC address, transmission interval, retransmission times, and recovery times based on the actual environment.

Configuring a DLDP Detection Mode

- Optional.
- You can configure active or passive DLDP detection in interface configuration mode based on the actual environment.
- If DLDP detection needs to be enabled at both ends of a Layer-3 link, you can configure passive DLDP detection at one end to save bandwidth and CPU resources.

Configuring DLDP Parameters Globally

- Optional.
- You can modify the parameters of DLDP detection on all ports in global configuration mode based on requirements. The parameters include the packet transmission interval, packet retransmission times, and recovery times.

Verification

- Display the device DLDP information, including the status and statistics of DLDP detection on all ports.

Related Commands

Enabling DLDP Detection

Command	**dldp** *ip-address* [*next-hop-ip*] [**mac-address** *mac-addr*] [**interval** *tick*] [**retry** *retry-num*] [**resume** *resume-num*]
Parameter Description	*ip-address*: Indicates the detected IP address. *next-hop-ip*: Indicates the next-hop IP address. *mac-addr*: Indicates the MAC address of the detected device to be bound. If the next-hop IP address is specified, bind the MAC address of the next-hop device. *tick*: Indicates the interval at which detection packets are transmitted. The value ranges from 5 to 6,000 ticks (1 tick = 10 ms). The default value is 100 ticks (1s). *retry-num*: The value ranges from 1 to 3,600. The default value is 4. *resume-num*: Indicates the recovery times. The value ranges from 1 to 200. The default value is 3.
Command Mode	Interface configuration mode
Usage Guide	The port to be enabled with DLDP detection must be a Layer-3 port, such as a router port, L3AP port, and SVI port.

Configuring a DLDP Detection Mode

Command	**dldp passive**

Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	You need to enable DLDP detection before configuring a DLDP detection mode.

Modifying DLDP Detection Parameters Globally

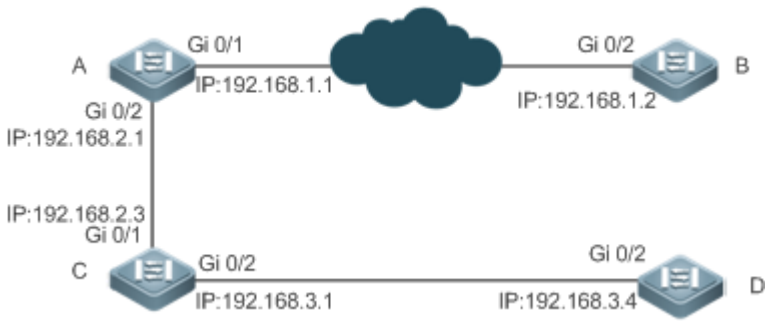
Command	**dldp** { **interval** *tick* | **retry** *retry-num* | **resume** *resume-num* }
Parameter Description	*tick*: Indicates the interval at which detection packets are transmitted. The value ranges from 5 to 6,000 ticks (1 tick = 10 ms). The default value is 100 ticks (1s). *retry-num*: Indicates the interval at which detection packets are retransmitted. The value ranges from 5 to 3,600. The default value is 4. *resume-num:* Indicates the recovery times. The value ranges from 1 to 200. The default value is 3.
Command Mode	Global configuration mode
Usage Guide	Use this command to quickly modify the parameters of DLDP detection on all ports when the actual environment is changed.

Displaying the DLDP Status

Command	**show dldp statistic** [**interface** *interface-name*]
Parameter Description	*interface-name*: Indicates the Layer-3 port on which the DLDP status will be displayed.
Command Mode	Privileged mode, global configuration mode, and interface configuration mode
Usage Guide	Use this command to display the DLDP status on a specific port. You can also use this command to display the DLDP status on all ports.

Configuration Example

Enabling DLDP Detection on Layer-3 Ports on Device A and Device B in a Layer-3 Network

Scenario Figure 11-3	
	


Verification	● Enable DLDP detection on the Gi 0/1 and Gi 0/2 router ports on Device A to detect the Layer-3 link connectivity between Device A and Device B and that between Device A and Device D. ● To control the Gi 0/2 router port of Device B, enable passive DLDP detection on the port.
A	A#configure terminal A(config)#interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#dldp 192.168.1.2 A(config-if-GigabitEthernet 0/1)# exit A(config)#interface GigabitEthernet 0/2 A(config-if-GigabitEthernet 0/1)#dldp 192.168.3.4 192.168.2.3
B	B#configure terminal B(config)#interface GigabitEthernet 0/2 B(config-if-GigabitEthernet 0/1)#dldp 192.168.1.1 B(config-if-GigabitEthernet 0/1)#dldp passive
Verification	● Display the DLDP status on Device A and Device B to check whether DLDP detection is enabled and works normally.
A	A# show dldp Interface Type Ip Next-hop Interval Retry Resume State --------- ------- ---------- ---------- -------- ----- ------ ------ Gi0/1 Active 192.168.1.2 100 4 3 Up Gi0/1 Active 192.168.3.4 192.168.2.3 100 4 3 Up
B	B# show dldp Interface Type Ip Next-hop Interval Retry Resume State --------- ------- ---------- ---------- -------- ----- ------ ------ Gi0/2 Passive 192.168.1.1 100 4 3 Up

Common Errors

- An unreachable IPv4 unicast route is misjudged as a DLDP detection failure.
- DLDP detection fails because the peer device does not support ARP/ICMP replies.
- No next-hop IP address is configured in inter-network segment DLDP detection.

11.5 Monitoring

Clearing

Description	Command
Clears DLDP statistics.	**clear dldp** [**interface** *interface-name* [*ip-address*]]

Displaying

Description	Command
Displays the DLDP status.	**show dldp** [**interface** *interface-name*]
Displays the DLDP statistics on the Up/Down port sates.	**show dldp statistic**

1 Configuring IP Addresses and Services

1.1 Overview

Internet Protocol (IP) sends packets to the destination from the source by using logical (or virtual) addresses, namely IP addresses. At the network layer, routers forward packets based on IP addresses.

Protocols and Standards

- RFC 1918: Address Allocation for Private Internets
- RFC 1166: Internet Numbers

1.2 Applications

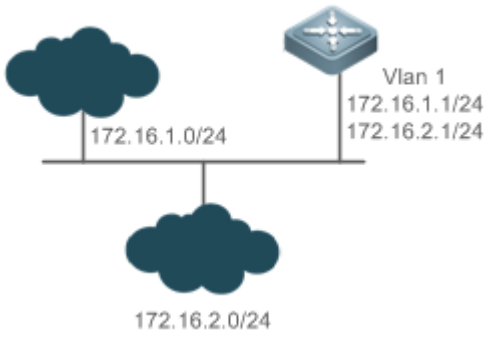
Application	Description
Configuring an IP Address for Communication	Two networks communicate through one switch interface.

1.2.1 Configuring an IP Address for Communication

Scenario

A switch is connected to a Local Area Network (LAN), which is divided into two network segments, namely, 172.16.1.0/24 and 172.16.2.0/24. Computers in the two network segments can communicate with the Internet through switches and computers between the two network segments can communicate with each other.

Figure 1-1Configuring IP Addresses



Deployment

- Configure two IP addresses on VLAN1. One is a primary IP address and the other is a secondary IP address.

- On hosts in the network segment 172.16.1.0/24, set the gateway to 172.16.1.1; on hosts in the network segment 172.16.2.0/24, set the gateway to 172.16.2.1.

1.3 Features

Basic Concepts

IP Address

An IP address consists of 32 bits in binary. To facilitate writing and description, an IP address is generally expressed in decimal. When expressed in decimal, an IP address is divided into four groups, with eight bits in each group. The value range of each group is from 0 to 255, and groups are separated by a full stop ".". For example, "192.168.1.1" is an IP address expressed in decimal.

IP addresses are used for interconnection at the IP layer. A 32-bit IP address consists of two parts, namely, the network bits and the host bits. Based on the values of the first several bits in the network part, IP addresses in use can be classified into four classes.

For a class A address, the most significant bit is 0.7 bits indicate a network ID, and 24 bits indicate a local address. There are 128 class A networks in total.

Figure 1-2

		8	16 24 32
Class A IP address	0	Network ID	Host ID

For a class B address, the first two most significant bits are 10.14 bits indicate a network ID, and 16 bits indicate a local address. There are 16,348 class B networks in total.

Figure 1-3

			8	16 24 32
Class B IP address	1	0	Network ID	Host ID

For a class C address, the first three most significant bits are 110.21 bits indicate a network ID, and 8 bits indicate a local address. There are 2,097,152 class C networks in total.

Figure 1-4

				8	16 24 32
Class C IP address	1	1	0	Network ID	Host ID

For a class D address, the first four most significant bits are 1110 and other bits indicate a multicast address.

Figure 1-5

					8	16	24	32
Class D IP address	1	1	1	0	Multicast address			

The addresses with the first four most significant bits 1111 cannot be assigned. These addresses are called class E addresses and are reserved.

When IP addresses are planned during network construction, IP addresses must be assigned based on the property of the network to be built. If the network needs to be connected to the Internet, users should apply for IP addresses to the corresponding agency. In China, you can apply to China Internet Network Information Center (CNNIC) for IP addresses. Internet Corporation for Assigned Names and Numbers (ICANN) is the final organization responsible for IP address assignment. If the network to be built is an internal private network, users do not need to apply for IP addresses. However, IP addresses cannot be assigned at random. It is recommended to assign dedicated private network addresses.

The following table lists reserved and available addresses.

Class	Address Range	Status
Class A network	0.0.0.0 - 0.255.255.255	Reserved
	1.0.0.0 - 126.255.255.255	Available
	127.0.0.0 - 127.255.255.255	Reserved
Class B network	128.0.0.0 - 191.254.255.255	Available
	191.255.0.0 - 191.255.255.255	Reserved
Class C network	192.0.0.0 - 192.0.0.255	Reserved
	192.0.1.0 - 223.255.254.255	Available
	223.255.255.0 - 223.255.255.255	Reserved
Class D network	224.0.0.0 - 239.255.255.255	Multicast address
Class E network	240.0.0.0 - 255.255.255.254	Reserved
	255.255.255.255	Broadcast address

Three address ranges are dedicated to private networks. These addresses are not used in the Internet. If the networks to which these addresses are assigned need to be connected to the Internet, these IP addresses need to be converted into valid Internet addresses. The following table lists private address ranges. Private network addresses are defined in RFC 1918.

Class	Address Range	Status
Class A network	10.0.0.0 - 10.255.255.255	1 class A network
Class B network	172.16.0.0 - 172.31.255.255	16 class B networks
Class C network	192.168.0.0 - 192.168.255.255	256 class C networks

For assignment of IP addresses, TCP/UDP ports, and other codes, refer to RFC 1166.

Subnet Mask

A subnet mask is also a 32-bit value. The bits that identify the IP address are the network address. In a subnet mask, the IP address bits corresponding to the bits whose values are 1s are the network address, and the IP address bits corresponding to the bits whose values are 0s are the host address. For example, for class A networks, the subnet mask is 255.0.0.0. By using network masks, you can divide a network into several subnets. Subnetting means to use some bits of the host address as the network address, thus decreasing the host capacity, and increasing the number of networks. In this case, network masks are called subnet masks.

Broadcast Packet

Broadcast packets refer to the packets destined for all hosts on a physical network. Ruijie products support two types of broadcast packets: (1) directed broadcast, which indicates that all hosts on the specified network are packet receivers and the host bits of a destination address are all 1s; (2) limited broadcast, which indicates that all hosts on all networks are packet receivers and the 32 bits of a destination address are all 1s.

ICMP Packet

Internet Control Message Protocol (ICMP) is a sub-protocol in the TCP/IP suite for transmitting control messages between IP hosts and network devices. It is mainly used to notify corresponding devices when the network performance becomes abnormal.

TTL

Time To Live (TTL) refers to the number of network segments where packets are allowed to pass before the packets are discarded. The TTL is a value in an IP packet. It informs the network whether packets should be discarded as the packets stay on the network for a long time.

Features

Feature	Description
IP Address	The IP protocol can run on an interface only after the interface is configured with an IP address.
Broadcast Packet Processing	Broadcast addresses are configured and broadcast packets are forwarded and processed.
Sending ICMP Packets	ICMP packets are sent and received.
Limiting Transmission Rate of ICMP Error Packets	This function prevents Denial of Service (DoS) attacks.
IP MTU	Maximum Transmission Unit (MTU) of IP packets on an interface is configured.
IP TTL	The TTL of unicast packets and broadcast packets is configured.
IP Source Route	Source routes are checked.

1.3.1 IP Address

IP addresses are obtained on an interface in the following ways:

1. Manually configuring IP addresses
2. Obtaining IP addresses through DHCP
3. Obtaining IP addresses through PPP negotiation
4. Borrowing IP addresses of other interfaces

These approaches are mutually exclusive. If you configure a new approach to obtain an IP address , the old IP address will be overwritten.

For details on how to obtain IP addresses through DHCP, see the “DHCP” chapter. The following describes the other three approaches for obtaining IP addresses.

Configuring the IP Address for an Interface

A device can receive and send IP packets only after the device is configured with an IP address. Only the interface configured with an IP address can run the IP protocol.

Configuring Multiple IP Addresses for an Interface

Ruijie products support multiple IP address configuration on one interface, of which one is a primary IP address and the others are secondary IP addresses or slave addresses. Theoretically, the number of secondary IP addresses is not limited. However, secondary IP addresses must belong to different networks and secondary IP addresses must be in different networks from primary IP addresses. In network construction, secondary IP addresses are often used in the following circumstances:

- A network does not have enough host addresses. For example, a LAN now needs one class C network to allocate 254 addresses. However, when the number of hosts exceeds 254, one class C network is not enough and another class C network is needed. In this case, two networks need to be connected. Therefore, more IP addresses are needed.
- Many old networks are based on L2 bridged networks without subnetting. You can use secondary IP addresses to upgrade the network to a routing network based on IP layer. For each subnet, one device is configured with one IP address.
- When two subnets of one network are isolated by another network, you can connect the isolated subnets by creating a subnet of the isolated network and configuring a secondary address. One subnet cannot be configured on two or more interfaces of a device.

Before configuring secondary IP addresses, make sure that primary IP addresses are configured. If one device in a network is configured with a secondary IP address, other devices must be configured with secondary IP addresses in the same network. If other devices are not configured with IP addresses, the secondary addresses can be set to primary IP addresses.

Obtaining an IP Addresses through PPP Negotiation

This command is supported on point-to-point interfaces only.

Through this configuration, a point-to-point interface accepts the IP address assigned by the peer end through PPP negotiation.

Borrowing an IP Addresses from Another Interface

One interface may not be configured with an IP address. To enable the interface, it must borrow an IP address from another interface.

- IP addresses of Ethernet interfaces, tunnel interfaces, and loopback interfaces can be borrowed. However, these interfaces cannot borrow IP addresses from other interfaces.
- The IP addresses of borrowed interfaces cannot be borrowed from other interfaces.
- If a borrowed interface has multiple IP addresses, only the primary IP address can be borrowed.
- The IP address of one interface can be lent to multiple interfaces.
- IP addresses of borrowing interfaces are always consistent with and vary with IP addresses of borrowed interfaces.

Configuring the IP Address of a BVI Interface on an AP through AC

- The configuration modes on an Access Controller (AC) include ap-config apname, ap-group, and ap-config, with priorities in a descending order. The configuration pushed to an Access Point (AP) is the configuration in the highest priority.
- In any AP configuration mode, you can configure an IP address for only one BVI interface by using either the **ap-interface bvi** *num***ip address** *ip-address network-mask* command or the **ap-interface bvi** *num***ip address dynamic** command.
- In a Fit AP network, if the **ap-interface bvi** *num***ip address** *ip-address network-mask* command is used, the AP needs to be assigned within different VLANs. Otherwise, an address conflict occurs. If the **ap-interface bvi** *num***ip address dynamic** command is used, the problem does not occur.

Related Configuration

Configuring an Interface with One or More IP Addresses

- By default, an interface is not configured with an IP address.
- The **ip address** command is used to configure an IP address for an interface.
- After an IP address is configured, the IP address can be used for communication when it passes conflict detection.
- The **ip address** *ip-address mask* **secondary** command can be used to configure multiple secondary IP addresses.

Obtaining an IP Address through PPP Negotiation

- By default, the interface cannot obtain an IP address through PPP negotiation.
- The **ip address negotiate** command is used to configure IP address negotiation on a point-to-point interface.

Borrowing an IP Address from Other Interfaces

- By default, an interface is not configured with an IP address.
- The **ip unnumbered** command can be used to borrow IP addresses from other interfaces.

Configuring the IP Address of a BVI Interface on an AP through AC

- By default, the IP address of a BVI interface is not configured in AP configuration mode.
- The **ap-interface bvi** *num* **ip address** command is used to configure the IP address of a BVI interface of an AP on an AC.

1.3.2 Broadcast Packet Processing

Working Principle

Broadcast is divided into two types. One is limited broadcast, and the IP address is 255.255.255.255. Because the broadcast is prohibited by routers, the broadcast is called local network broadcast. The other is directed broadcast. All host bits are 1s, for example, 192.168.1.255/24. The broadcast packets with these IP addresses can be forwarded.

If IP network devices forward limited broadcast packets (destination IP address is 255.255.255.255), the network may be overloaded, which severely affects network performance. This circumstance is called broadcast storm. Devices provide some approaches to confine broadcast storms within the local network and prevent continuous spread of broadcast storms. L2 network devices such as bridges and switches forward and spread broadcast storms.

The best way to avoid broadcast storm is to assign a broadcast address to each network, which is directed broadcast. This requires the IP protocol to use directed broadcast rather than limited broadcast to spread data.

For details about broadcast storms, see RFC 919 and RFC 922.

Directed broadcast packets refer to the broadcast packets destined for a subnet. For example, packets whose destination address is 172.16.16.255 are called directed broadcast packets. However, the node that generates the packets is not a member of the destination subnet.

After receiving directed broadcast packets, the devices not directly connected to the destination subnet forward the packets. After directed broadcast packets reach the devices directly connected to the subnet, the devices convert directed broadcast packets to limited broadcast packets (destination IP address is 255.255.255.255) and broadcast the packets to all hosts on the destination subnet at the link layer.

Related Configuration

↘ Configuring an IP Broadcast Address

- By default, the IP broadcast address of an interface is 255.255.255.255.
- To define broadcast packets of other addresses, run the **ip broadcast-address** command on the interface.

↘ Forwarding Directed Broadcast Packets

- By default, directed broadcast packets cannot be forwarded.
- On the specified interface, you can run the **ip directed-broadcast** command to enable directed broadcast packets forwarding. In this way, the interface can forward directed broadcast packets to networks that are directly connected. Broadcast packets can be transmitted within the destination subnet without affecting forwarding of other directed broadcast packets.
- On an interface, you can define an Access Control List (ACL) to transmit certain directed broadcast packets. After an ACL is defined, only directed broadcast packets that match the ACL are forwarded.

1.3.3 Sending ICMP Packets

Working Principle

ICMP Protocol Unreachable Message

A device receives non-broadcast packets destined for itself, and he packets contain the IP protocol that cannot be processed by the device. The device sends an ICMP protocol unreachable message to the source host. Besides, if the device does not know a route to forward packets, it also sends an ICMP host unreachable message.

ICMP Redirection Message

Sometimes, a route may be less than optimal, which makes a device send packets from the interface that receives packets. If a device sends packets from an interface on which it receives the packets, the device sends an ICMP redirection message to the source, informing the source that the gateway is another device on the same subnet. In this way, the source sends subsequent packets according to the optimal path.

ICMP Mask Response Message

Sometimes, a network device sends an ICMP mask request message to obtain the mask of a subnet.. The network device that receives the ICMP mask request message sends a mask response message.

Related Configuration

Enabling ICMP Protocol Unreachable Message

- By default, the ICMP Protocol unreachable message function is enabled on an interface.
- You can run the [**no**] **ip unreachables** command to disable or enable the function.

Enabling ICMP Redirection Message

- By default, the ICMP redirection message function is enabled on an interface.
- You can run the [**no**] **ip redirects** command to disable or enable the function.

Enabling ICMP Mask Response Message

- By default, the ICMP mask response message function is enabled on an interface.
- You can run the [**no**] **ip mask-reply** command to disable or enable the function.

Enabling Returning of a Timestamp Reply

- By default, returning of a Timestamp Reply is enabled.
- You can run the [**no**] **ip icmp timestamp** command to disable or enable the function.

1.3.4 Limiting Transmission Rate of ICMP Error Packets

Working Principle

This function limits the transmission rate of ICMP error packets to prevent DoS attacks by using the token bucket algorithm.

If an IP packet needs to be fragmented but the Don't Fragment (DF) bit in the header is set to 1, the device sends an ICMP destination unreachable packet (code 4) to the source host. This ICMP error packet is used to discover the path MTU. When there are too many other ICMP error packets, the ICMP destination unreachable packet (code 4) may not be sent. As a result, the path MTU discovery function fails. To avoid this problem, you should limit the transmission rate of ICMP destination unreachable packets and other ICMP error packets respectively.

Related Configuration

Configuring the Transmission Rate of ICMP Destination Unreachable Packets Triggered by DF Bit in the IP Header

- The default transmission rate is 10 packets every 100 milliseconds.
- The **ip icmp error-interval DF** command can be used to configure the transmission rate.

Configuring the Transmission Rate of Other ICMP Error Packets

- The default transmission rate is 10 packets every 100 milliseconds.
- The **ip icmp error-interval** command can be used to configure the transmission rate.

1.3.5 IP MTU

Working Principle

If an IP packet exceeds the IP MTU size, the RGOS software splits the packet. For all devices in the same physical network segment, the IP MTU of interconnected interfaces must be the same. You can adjust the link MTU of interfaces on Ruijie products. After the link MTU of interfaces is changed, the IP MTU of interfaces will be changed. The IP MTU of interfaces automatically keeps consistent with the link MTU of interfaces. However, if the IP MTU of interfaces is adjusted, the link MTU of interfaces will not be changed.

Related Configuration

Setting the IP MTU

- By default, the IP MTU of an interface is 1500.
- The **ip mtu** command can be used to set the IP packet MTU.

1.3.6 IP TTL

Working Principle

An IP packet is transmitted from the source address to the destination address through routers. After a TTL value is set, the TTL value decreases by 1 every time when the IP packet passes a router. When the TTL value drops to zero, the router discards the packet. This prevents infinite transmission of useless packets and waste of bandwidth.

Related Configuration

Setting the IP TTL

- By default, the IP TTL of an interface is 64.
- The **ip ttl** command can be used to set the IP TTL of an interface.

1.3.7 IP Source Route

Working Principle

Ruijie products support IP source routes. When a device receives an IP packet, it checks the options such as source route, loose source route, and record route in the IP packet header. These options are detailed in RFC 791. If the device detects that the packet enables one option, it responds; if the device detects an invalid option, it sends an ICMP parameter error message to the source and then discards the packet.

After the IP source route is enabled, the source route option is added to an IP packet to test the throughput of a specific network or help the packet bypasses the failed network. However, this may cause network attacks such as source address spoofing and IP spoofing.

Related Configuration

↘ **Configuring an IP Source Route**

- By default, the IP source route function is enabled.
- The **ip source-route** command can be used to enable or disable the function.

1.3.8 IP Address Pool

Working Principle

A point-to-point interface can assign an IP address to the peer end through PPP negotiation. During PPP negotiation, the server checks authentication information of the client. If the client passes the authentication, the server assigns an IP address to the client (if the client is configured with an IP address and the IP address meets requirements of the server, the server approves the IP address of the client). The IP address of the peer end can be directly specified or assigned from the address pool.

Related Configuration

↘ **Enabling the Address Pool Function**

- By default, the address pool function is enabled.
- The **ip address-pool local** command can be used to enable or disable the function.

↘ **Creating an Address Pool**

- By default, no IP address pool is configured.
- The **ip local pool** command can be used to create or delete an address pool.

↘ **Assigning an IP Address to the Peer End through PPP Negotiation**

- By default, an interface does not assign an IP address to the peer end.
- The **peer default ip address** command can be used to assign an IP address to the peer end.

1.4 Configuration

Configuration	Description and Command	
Configuring the IP Addresses of an Interface	⚠ (Mandatory) It is used to configure an IP address and allow the IP protocol to run on an interface.	
	ip address	Manually configures the IP address of an interface.
	ip address negotiate	Obtains the IP address of an interface through PPP negotiation.
	ip unnumbered	Borrows an IP address from another interface.
	ap-interface bvi *num* **ip address**	Configures the IP address of a BVI interface on an AP through AC.
Configuring Broadcast Forwarding	⚠ (Optional) It is used to set an IP broadcast address and enable directed broadcast forwarding.	
	ip broadcast-address	Configures an IP broadcast address.
	ip directed-broadcast	Enables directed broadcast forwarding.
Configuring ICMP Forwarding	⚠ (Optional) It is used to enable ICMP packet forwarding.	
	ip unreachables	Enables ICMP unreachable messages and host unreachable messages.
	ip redirects	Enables ICMP redirection messages.
	ip mask-reply	Enables ICMP mask response messages.
	ip icmp timestamp	Enables returning of a Timestamp Reply.
Configuring the Transmission Rate of ICMP Error Packets	⚠ Optional.	
	ip icmp error-interval DF	Configures the transmission rate of ICMP destination unreachable packets triggered by the DF bit in the IP header.
	ip icmp error-interval	Configures the transmission rate of ICMP error packets and ICMP redirection packets.
Setting the IP MTU	⚠ (Optional) It is used to configure the IP MTU on an interface.	
	ip mtu	Sets the MTU value.
Setting the IP TTL	⚠ (Optional) It is used to configure the TTL of unicast packets and broadcast packets.	

Configuration	Description and Command	
	ip ttl	Sets the TTL value.
Configuring an IP Source Route	(Optional) It is used to check the source routes.	
	ip source-route	Enables the IP source route function.

1.4.1 Configuring the IP Addresses of an Interface

Configuration Effect

Configure the IP address of an interface for communication.

Notes

- N/A

Configuration Steps

Configuring the IP Address of an Interface

- Mandatory
- Perform the configuration in L3 interface configuration mode.

Obtaining the IP Address of an Interface through PPP Negotiation

- If a point-to-point interface is not configured with an IP address, obtain an IP address through PPP negotiation.
- Perform the configuration in L3 interface configuration mode.

Borrowing an IP Address from Another Interface

- Optional
- If a point-to-point interface is not configured with an IP address, borrow an IP address from another interface.
- Perform the configuration in L3 interface configuration mode.

Verification

Run the **show ip interface** command to check whether the configuration takes effect.

Related Commands

Manually Configuring the IP Address of an Interface

Command	**ip address** *ip-address network-mask* [**secondary**]
Parameter Description	*ip-address*: 32-bit IP address, with 8 bits for each group. The IP address is expressed in decimal and groups are separated by a full stop (.). *network-mask*: 32-bit network mask. Value 1 indicates the mask bit and 0 indicates the host bit. Every 8 bits form one group. The network mask is expressed in decimal and groups are separated by a full stop (.). **secondary**: Secondary IP address.

Command Mode	Interface configuration mode
Usage Guide	N/A

Obtaining an IP Address of an Interface through PPP Negotiation

Command	**ip address negotiate**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Only point-to-point interfaces support obtaining IP addresses through PPP negotiation. After the **ip address negotiate** command is run on an interface, run the **peer default ip address** command at the peer end.

Borrowing an IP Addresses from Another Interface

Command	**ip unnumbered** *interface-type interface-number*
Parameter Description	*interface-type*: Interface type. *interface-number*: Interface ID.
Command Mode	Interface configuration mode
Usage Guide	An unnumbered interface indicates that the interface is enabled with the IP protocol without an IP address assigned. An unnumbered interface needs to be associated with an interface configured with an IP address. For an IP packet generated on an unnumbered interface, the source IP address of the packet is the IP address of the associated interface. In addition, the routing protocol process decides whether to send a route update packet to the unnumbered interface according to its associated IP address. If you want to use an unnumbered interface, pay attention to the following limitations: An Ethernet interface cannot be set to an unnumbered interface. When a serial interface encapsulates SLIP, HDLC, PPP, LAPB, and Frame-Relay, the serial interface can be set to an unnumbered interface. During Frame -Relay encapsulation, however, only a point-to-point interface can be configured as an unnumbered interface. AnX.25 interface cannot be configured as an unnumbered interface. The **ping** command cannot be used to check whether an unnumbered interface is working properly because an unnumbered interface is not configured with an IP address. However, you can monitor the status of an unnumbered interface remotely through SNMP. A device cannot be cold started through an unnumbered interface.

Configuring the IP Address of a BVI Interface on an AP through AC

Command	**ap-interface bvi** *num***ip address** {*ip-address network-mask* | **dynamic**}
Parameter Description	*num*: BVI interface ID. *ip-address*: 32-bit IP address, with 8 bits for each group. The IP address is expressed in decimal and groups

	are separated by a full stop (.). *network-mask*: 32-bit network mask. Value 1 indicates the mask bit and 0 indicates the host bit. **dynamic:** Configures the IP address and mask of a BVI interface on an AP by dynamically obtaining IP addresses and masks.
Command Mode	AP configuration mode/AP group configuration mode
Usage Guide	Run the command in AP configuration mode () or AP group configuration mode. In other words, the configuration modes on an AC include ap-config apname, ap-group, and ap-config, with priorities in a descending order. You can configure an IP address for only one BVI interface in any AP configuration mode. According to the priority, the AC selects the configuration of the highest priority and pushes it to the corresponding AP. ⚠ In a Fit AP network, if the **ap-interface bvi** *num***ip address** *ip-address network-mask* command is used, the AP needs to be assigned within different VLANs. Otherwise, an address conflict occurs. If the **ap-interface bvi** *num***ip address dynamic** command is used, the problem does not occur.

Configuration Example

↘ Configuring an IP Address for an Interface

Configuration Steps	Configure IP address 192.168.23.110 255.255.255.0 on interface GigabitEthernet 0/0.
	Ruijie#configure terminal Ruijie(config)#interface gigabitEthernet 0/0 Ruijie(config-if-GigabitEthernet 0/0)# no switchport Ruijie(config-if-GigabitEthernet 0/0)#ip address 192.168.23.110 255.255.255.0
Verification	Run the **show ip interface** command to check whether the configuration takes effect.
	Ruijie# show ip interface gigabitEthernet 0/0 GigabitEthernet 0/0 IP interface state is: UP IP interface type is: BROADCAST IP interface MTU is: 1500 IP address is: 192.168.23.110/24 (primary)

↘ Obtaining the IP Address of an Interface through PPP Negotiation

Configuration Steps	Obtain the IP address of an interface through PPP negotiation.

	Ruijie(config)#int virtual-ppp 1 Ruijie(config-if-Virtual-ppp 1)#ip address negotiate
Verification	Run the **show run** command on the AC to display the configuration.
	Ruijie#show run interface virtual-ppp 1 Building configuration... Current configuration: 48 bytes interface Virtual-ppp 1 ip address negotiate

Configuring the IP Address of a BVI Interface on an AP through AC

Configuration Steps	Configure the IP address of a BVI 2 interface of an AP to 192.168.2.1 255.255.255.0 in ap-config ap120 mode.
	Ruijie(config)#ap-config ap120 You are going to config AP(ap120), which is online now. Ruijie(config-ap)#ap-interface bvi 2 ip address 192.168.2.1 255.255.255.0
Verification	Run the **show ap-config running-config** command on the AC to check whether the configuration takes effect.
	Ruijie# show ap-config running-config ap-config ap120 ap-interface bvi 2 ip address 192.168.2.1 255.255.255.0
	Run the **show ip interface brief** command on the AP to check whether the configuration takes effect.
	Ruijie# show ip interface brief Interface IP-Address(Pri) IP-Address(Sec) Status Protocol BVI 2 192.168.2.1/24 no address up up

1.4.2 Configuring Broadcast Forwarding

Configuration Effect

Set the broadcast address of an interface to 0.0.0.0 and enable directed broadcast forwarding.

Notes

N/A

Configuration Steps

Configuring an IP Broadcast Address

- (Optional) Some old hosts may identify broadcast address 0.0.0.0 only. In this case, set the broadcast address of the target interface to 0.0.0.0.
- Perform the configuration in L3 interface configuration mode.

Enabling Directed Broadcast Forwarding

- (Optional) If you want to enable a host to send broadcast packets to all hosts in a domain that it is not in, enable directed broadcast forwarding.
- Perform the configuration in L3 interface configuration mode.

Verification

Run the **show running-config interface** command to check whether the configuration takes effect.

Related Commands

Configuring an IP Broadcast Address

Command	**ip broadcast-address** *ip-address*
Parameter Description	*ip-address*: Broadcast address of an IP network.
Command Mode	Interface configuration mode
Usage Guide	Generally, the destination address of IP broadcast packets is all 1s, which is expressed as 255.255.255.255. The RGOS software can generate broadcast packets of other IP addresses through definition and receive self-defined broadcast packets and the broadcast packets with address 255.255.255.255.

Allowing Forwarding of Directed Broadcast Packets

Command	**ip directed-broadcast** [*access-list-number*]
Parameter Description	*access-list-number*: Access list number, ranging from 1 to 199 and from1300 to 2699. After an ACL is defined, only directed broadcast packets that match the ACL are forwarded.
Command Mode	Interface configuration mode
Usage Guide	If the **no ip directed-broadcast** command is run on an interface, the RGOS software will discard directed broadcast packets received from the network that is directly connected.

Configuration Example

Configuration Steps	On interface gigabitEthernet 0/1, set the destination address of IP broadcast packets to 0.0.0.0 and enable directed broadcast forwarding. `Ruijie#configure terminal` `Ruijie(config)#interface gigabitEthernet 0/1` `Ruijie(config-if-GigabitEthernet 0/1)# no switchport` `Ruijie(config-if-GigabitEthernet 0/1)#ip broadcast-address 0.0.0.0` `Ruijie(config-if-GigabitEthernet 0/1)#ip directed-broadcast`
Verification	Run the **show ip interface** command to check whether the configuration takes effect. `Ruijie#show running-config interface gigabitEthernet 0/1` `ip directed-broadcast` `ip broadcast-address 0.0.0.0`

1.4.3 Configuring ICMP Forwarding

Configuration Effect

Enable ICMP unreachable messages, ICMP redirection messages, and mask response messages on an interface.

Notes

N/A

Configuration Steps

Enabling ICMP Unreachable Messages

- By default, ICMP unreachable messages are enabled.
- Optional)The **no ip unreachables** command can be used to disable ICMP unreachable messages.
- Perform the configuration in L3 interface configuration mode.

Enabling ICMP Redirection Messages

- By default, ICMP redirection messages are enabled.
- Optional)The **no ip redirects** command can be used to disable ICMP redirection messages.
- Perform the configuration in L3 interface configuration mode.

Enabling ICMP Mask Response Messages

- By default, ICMP mask response messages are enabled.
- Optional)The **no ip mask-reply** command can be used to disable ICMP mask response messages.
- Perform the configuration in L3 interface configuration mode.

Enabling Returning of a Timestamp Reply

- By default, Tmestamp Replies are enabled.
- Optional)The **no ip icmp timestamp** command can be used to disable Temestamp Replies.
- Perform the configuration in global configuration mode.

Verification

Run the **show ip interface** command to check whether the configuration takes effect.

Related Commands

Enabling ICMP Unreachable Messages

Command	**ip mask-reply**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Disabling Timestamp Replies

Command	**no ip icmp timestamp**
Parameter Description	N/A
Command Mode	Global configuration mode

Usage Guide	N/A

Configuration Example

Configuration Steps	Enable ICMP unreachable messages, ICMP redirection messages, and mask response messages on interface gigabitEthernet 0/1.
	Ruijie#configure terminal Ruijie(config)#interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# no switchport Ruijie(config-if-GigabitEthernet 0/1)# ip unreachables Ruijie(config-if-GigabitEthernet 0/1)# ip redirects Ruijie(config-if-GigabitEthernet 0/1)# ip mask-reply
Verification	Run the **show ip interface** command to check whether the configuration takes effect.
	Ruijie#show ip interface gigabitEthernet 0/1 GigabitEthernet 0/1 ICMP mask reply is: ON Send ICMP redirect is: ON Send ICMP unreachabled is: ON

1.4.4 Configuring the Transmission Rate of ICMP Error Packets

Configuration Effect

Configure the transmission rate of ICMP error packets.

Notes

N/A

Configuration Steps

Configuring the Transmission Rate of ICMP Destination Unreachable Packets Triggered by the DF Bit in the IP Header

- Optional
- Perform the configuration in global configuration mode.

Configuring the Transmission Rate of Other ICMP Error Packets

- Optional
- Perform the configuration in global configuration mode.

Enabling Returning of a Timestamp Reply

- By default, returning of a Timestamp Reply is enabled.
- You can run the [**no**] **ip icmp timestamp** command to disable or enable the function.

Verification

Run the **show running-config** command to check whether the configuration takes effect.

Related Commands

Configuring the Transmission Rate of ICMP Destination Unreachable Packets Triggered by the DF Bit in the IP Header

Command	**ip icmp error-interval DF** *milliseconds* [*bucket-size*]
Parameter Description	*milliseconds*: Refresh cycle of a token bucket. The value range is from 0 to 2,147,483,647 and the default value is 100 milliseconds. When the value is 0, the transmission rate of ICMP error packets is not limited. *bucket-size*: Number of tokens contained in a token bucket. The value range is from 1 to 200 and the default value is 10.
Command Mode	Global configuration mode.
Usage Guide	This function limits the transmission rate of ICMP error packets to prevent DoS attacks by using the token bucket algorithm. If an IP packet needs to be fragmented but the DF bit in the header is set to 1, the device sends an ICMP destination unreachable packet (code 4) to the source host. This ICMP error packet is used to discover the path MTU. When there are too many other ICMP error packets, the ICMP destination unreachable packet (code 4) may not be sent. As a result, the path MTU discovery function fails. To avoid this problem, you should limit the transmission rate of ICMP destination unreachable packets and other ICMP error packets respectively. It is recommended to set the refresh cycle to integral multiples of 10 milliseconds. If the refresh cycle is set to a value greater than 0 and smaller than 10 milliseconds, the refresh cycle that actually takes effect is 10 milliseconds. For example, if the refresh rate is set to 1 per 5 milliseconds, the refresh rate that actually takes effect is 2 per 10 milliseconds. If the refresh cycle is not integral multiples of 10 milliseconds, the refresh cycle that actually takes effect is automatically converted to integral multiples of 10 milliseconds. For example, if the refresh rate is set to 3 per 15 milliseconds, the refresh rate that actually takes effect is 2 per 10milliseconds.

Configuring the Transmission Rate of Other ICMP Error Packets

Command	**ip icmp error-interval** *milliseconds* [*bucket-size*]
Parameter Description	*milliseconds*: Refresh cycle of a token bucket. The value range is 0to 2,147,483,647, and the default value is **100** (ms). When the value is **0**, the transmission rate of ICMP error packets is not limited. *bucket-size*: Number of tokens contained in a token bucket. The value range is 1to 200 and the default value is **10**.

Command Mode	Global configuration mode.
Usage Guide	This function limits the transmission rate of ICMP error packets to prevent DoS attacks by using the token bucket algorithm. It is recommended to set the refresh cycle to integral multiples of 10 milliseconds. If the refresh cycle is set to a value greater than 0 and smaller than 10 milliseconds, the refresh cycle that actually takes effect is 10 milliseconds. For example, if the refresh rate is set to 1 per 5 milliseconds, the refresh rate that actually takes effect is 2 per 10 milliseconds. If the refresh cycle is not integral multiples of 10 milliseconds, the refresh cycle that actually takes effect is automatically converted to integral multiples of 10 milliseconds. For example, if the refresh rate is set to 3 per 15 milliseconds, the refresh rate that actually takes effect is 2 per 10 milliseconds.

Disabling Returning of Timestamp Reply

Command	**no ip icmp timestamp**
Parameter Description	N/A
Command Mode	Global configuration mode.
Usage Guide	N/A

Configuration Example

Configuration Steps	Set the transmission rate of ICMP destination unreachable packets triggered the DF bit in IP header to 100 packets per second and the transmission rate of other ICMP error packets to 10 packets per second.
	`Ruijie(config)# ip icmp error-interval DF 1000 100` `Ruijie(config)# ip icmp error-interval 1000 10`
Verification	Run the **show running-config** command to check whether the configuration takes effect.
	`Ruijie#show running-config | include ip icmp error-interval` `ip icmp error-interval 1000 10` `ip icmp error-interval DF 1000 100`

1.4.5 Setting the IP MTU

Configuration Effect

Adjust the IP packet MTU.

Notes

N/A

Configuration Steps

- (Optional) When the IP MTU of interconnected interfaces is different on devices in the same physical network segment, set the IP MTU to the same value.
- Perform the configuration in L3 interface configuration mode.

Verification

Run the **show ip interface** command to check whether the configuration takes effect.

Related Commands

↘ Setting the IP MTU

Command	**ip mtu** *bytes*
Parameter Description	*bytes*: IP packet MTU. The value range is from 68 to 1,500 bytes.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuration Steps	Set the IP MTU of interface gigabitEthernet 0/1 to 512 bytes.
	Ruijie#configure terminal Ruijie(config)#interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# no switchport Ruijie(config-if-GigabitEthernet 0/1)#ip mtu 512
Verification	Run the **show ip interface** command to check whether the configuration takes effect.
	Ruijie# show ip interface gigabitEthernet 0/1 IP interface MTU is: 512

1.4.6 Setting the IP TTL

Configuration Effect

Modify the IP TTL value of an interface.

Notes

N/A

Configuration Steps

- Optional

- Perform the configuration in L3 interface configuration mode.

Verification

Run the **show run-config** command to check whether the configuration takes effect.

Related Commands

Setting the IP TTL

Command	**ip ttl** *value*
Parameter Description	*value*: TTL value. The value range is from 0 to 255.
Command Mode	Global configuration mode.
Usage Guide	N/A

Configuration Example

Configuration Steps	• Set the TTL of unicast packets to 100.
	Ruijie#configure terminal Ruijie(config)#ip ttl 100
Verification	Run the **show run-config** command to check whether the configuration takes effect.
	Ruijie#show running-config ip ttl 100

1.4.7 Configuring an IP Source Route

Configuration Effect

Enable or disable the IP source route function.

Notes

N/A

Configuration Steps

- By default, the IP source route function is enabled.
- Optional) The **no ip source-route** command can be used to disable the IP source route function.

Verification

Run the **show run-config** command to check whether the configuration takes effect.

Related Commands

Configuring an IP Source Route

Command	**ip source-route**
Parameter Description	N/A
Command Mode	Global configuration mode.
Usage Guide	N/A

Configuration Example

Configuration Steps	● Disable the IP source route function.
	`Ruijie#configure terminal` `Ruijie(config)#no ip source-route`
Verification	Run the **show run-config** command to check whether the configuration takes effect.
	`Ruijie#show running-config` `no ip source-route`

1.4.8 Configuring an IP Address Pool

Configuration Effect

Assign an IP address to a client through PPP negotiation.

Notes

N/A

Configuration Steps

Enabling the IP Address Pool Function

- Optional
- Perform the configuration in global configuration mode.

Creating an IP Address Pool

- Optional
- An IP address pool can be created only after the IP address pool function is enabled. After the IP address pool function is disabled, the created address pool is automatically deleted.
- Perform the configuration in global configuration mode.

Assigning an IP Address to the Peer End through PPP Negotiation

- Optional
- Perform the configuration in L3 interface configuration mode.

Verification

Run the **show run-config** command to check whether the configuration takes effect.

Related Commands

Enabling the IP Address Pool Function

Command	**ip address-pool local**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, the IP address pool function is enabled. You can configure an IP address pool to assign an IP address to the peer end through PPP negotiation. To disable the IP address pool function, run the **no ip address-pool local** command. All IP address pools configured previously will be deleted.

Creating an IP Address Pool

Command	**ip local pool** *pool-namelow-ip-address*[*high-ip-address*]
Parameter Description	*pool-name*: Name of a local IP address pool. **default** indicates the default address pool name. *low-ip-address*: Smallest IP address in an IP address pool. *high-ip-address*: Optional)Largest IP address in an IP address pool. If the largest IP address is not specified, the IP address pool contains only one IP address, that is, *low-ip-address*.
Command Mode	Global configuration mode
Usage Guide	The command is used to create one or more IP address pools to assign IP addresses to peer ends through PPP negotiation.

Assigning an IP Address to the Peer End through PPP Negotiation

Command	**peer default ip address** {*ip-address* | **pool** [*pool-name*] }
Parameter Description	*ip-address*: IP address assigned to the peer end. *pool-name*: (Optional) Specifies the address pool that assigns IP addresses. If this parameter is not set, IP addresses are assigned from the default address pool.
Command Mode	Interface configuration mode
Usage Guide	If the peer end is not configured with an IP address while the local device is configured with an IP address, you can enable the local device to assign an IP address to the peer end. Run the **ip address negotiate** command on the peer end and the **peer default ip address** command on the local device so that the peer

	end can accept the IP address assigned through PPP negotiation. The **peer default ip address** command can be configured on only PPP or SLIP interfaces. The **peer default ip address pool** command is used to assign an IP address to the peer end from an IP address pool. The IP address pool is configured through the **ip local pool** command. The **peer default ip address** *ip-address* command is used to specify an IP address for the peer end. The command cannot be run on virtual template interfaces or asynchronous interfaces.

Configuration Example

Configuration Steps	● Assign an IP address from address pool “quark” to the peer end on interface “dialer1”.
	Ruijie#configure terminal Ruijie(config)# ip address-pool local Ruijie(config)# ip local pool quark 172.16.23.2 172.16.23.255 Ruijie(config)# interface dialer 1 Ruijie(config-if-dialer 1)#peer default ip address pool quark
Verification	Run the **show run-config** command to check whether the configuration takes effect.
	Ruijie#show running-config ip local pool quark 172.16.23.2 172.16.23.255 ! interface dialer 1 peer default ip address pool quark

1.5 Monitoring

Displaying

Description	Command
Displays the IP address of an interface.	**show ip interface** [*interface-typeinterface-number* | **brief**]
Displays IP packet statistics.	**show ip packet statistics** [**total** | *interface-name*]
Displays address pool statistics.	**show ip pool** [*pool-name*]

2 Configuring ARP

2.1 Overview

In a local area network (LAN), each IP network device has two addresses: 1) local address. Since the local address is contained in the header of the data link layer (DLL) frame, it is a DLL address. However, it is processed by the MAC sublayer at the DLL and thereby is usually called the MAC address. MAC addresses represent IP network devices on LANs. 2) network address. Network addresses on the Internet represent IP network devices and also indicate the networks where the devices reside.

In a LAN, two IP devices can communicate with each other only after they learn the 48-bit MAC address of each other. The process of obtaining the MAC address based on the IP address is called address resolution. There are two types of address resolution protocols: 1) Address Resolution Protocol (ARP); 2) Proxy ARP. ARP and Proxy ARP are described respectively in RFC 826 and RFC 1027.

ARP is used to bind the MAC address with the IP address. When you enter an IP address, you can learn the corresponding MAC address through ARP. Once the MAC address is obtained, the IP-MAC mapping will be saved to the ARP cache of the network device. With the MAC address, the IP device can encapsulate DLL frames and send them to the LAN. By default, IP and ARP packets on the Ethernet are encapsulated in Ethernet II frames.

Protocols and Standards

- RFC 826: An Ethernet Address Resolution Protocol
- RFC 1027: Using ARP to implement transparent subnet gateways

2.2 Applications

Application	Description
LAN-based ARP	A user learns the MAC addresses of other users in the same network segment through ARP.
Proxy ARP-based Transparent Transmission	With Proxy ARP, a user can directly communicate with users in another network without knowing that it exists.

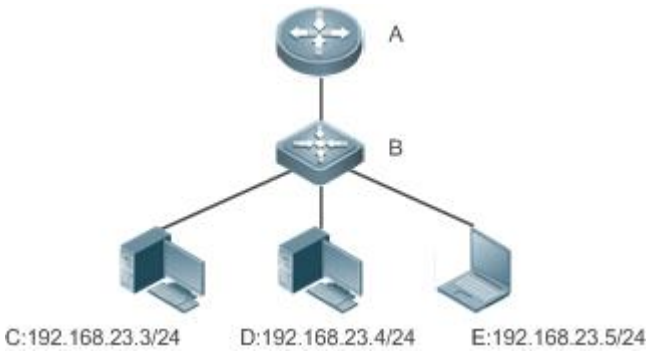
2.2.1 LAN-based ARP

Scenario

ARP is required in all IPv4 LANs.

- A user needs to learn the MAC addresses of other users through ARP to communicate with them.

Figure 2-1



Remarks	A is a router. B is a switch. It acts as the gateway. C, D, and E are hosts.

Deployment

- Enable ARP in a LAN to implement IP-MAC mapping.

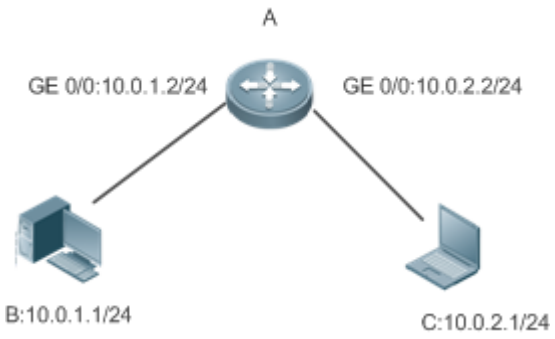
2.2.2 Proxy ARP-based Transparent Transmission

Scenario

Transparent transmission across IPv4 LANs is performed.

- Enable Proxy ARP on the router to achieve direct communication between users in different network segments.

Figure 2-2



Remarks	A is a router connecting two LANs. B and C are hosts in different subnets. No default gateway is configured for them.

Deployment

- Enable Proxy ARP on the subnet gateway. After configuration, the gateway can act as a proxy to enable a host without any route information to obtain MAC addresses of IP users in other subnets.

2.3 Features

Overview

Feature	Description
Static ARP	Users can manually specify IP-MAC mapping to prevent the device from learning incorrect ARP entries.
ARP Attributes	Users can specify the ARP entry timeout, ARP request retransmission times and interval, and maximum number of unresolved ARP entries.
Trusted ARP	Trusted ARP is used to prevent ARP spoofing.
Gratuitous ARP	Gratuitous ARP is used to detect IP address conflicts and enable peripheral devices to update ARP entries.
Proxy ARP	A proxy replies to the ARP requests from other devices in different subnets.
Local Proxy ARP	A proxy replies to the ARP requests from other devices in the same subnet.
ARP Trustworthiness Detection	Neighbor Unreachable Detection (NUD) is used to ensure that correct ARP entries are learned.
Disabling Dynamic ARP Entry Learning	After dynamic ARP learning is disabled on an interface, the interface does not learn dynamic ARP entries.

2.3.1 Static ARP

Static ARP entries can be configured manually or assigned by the authentication server. The manually configured ones prevail. Static ARP can prevent the device from learning incorrect ARP entries.

Working Principle

If static ARP entries are configured, the device does not actively update ARP entries and these ARP entries permanently exist.

When the device forwards Layer-3 packets, the static MAC address is encapsulated in the Ethernet header as the destination MAC address.

Related Configuration

↘ Enabling Static ARP

Run the **arp** *ip-address mac-address type* command in global configuration mode to configure static ARP entries. By default, no static ARP entry is configured. ARP encapsulation supports only the Ethernet II type, which is represented by ARPA.

2.3.2 ARP Attributes

Users can specify the ARP timeout, ARP request retransmission interval and times, maximum number of unresolved ARP entries, maximum number of ARP entries on an interface, and maximum number of ARP entries on a board.

Working Principle

ARP Timeout

The ARP timeout only applies to the dynamically learned IP-MAC mapping. When the ARP entry timeout expires, the device sends a unicast ARP request packet to detect whether the peer end is online. If it receives an ARP reply from the peer end, it does not delete this ARP entry. Otherwise, the device deletes this ARP entry.

When the ARP timeout is set to a smaller value, the mapping table stored in the ARP cache is more accurate but ARP consumes more network bandwidth.

ARP Request Retransmission Interval and Times

The device consecutively sends ARP requests to resolve an IP address to a MAC address. The shorter the retransmission interval is, the faster the resolution is. The more times the ARP request is retransmitted, the more likely the resolution will succeed and the more bandwidth ARP will consume.

Maximum Number of Unresolved ARP Entries

In a LAN, ARP attacks and scanning may cause a large number of unresolved ARP entries generated on the gateway. As a result, the gateway fails to learn the MAC addresses of the users. To prevent such attacks, users can configure the maximum number of unresolved ARP entries.

Maximum Number of ARP Entries on an Interface

Configure the maximum number of ARP entries on a specified interface to prevent ARP entry resource waste.

Maximum Number of ARP Entries on a Board

Configure the maximum number of ARP entries on a specified slot to limit their ARP capabilities and prevent ARP entry resource waste.

Related Configuration

Configuring the ARP Timeout

Run the **arp timeout** *seconds* command in interface configuration mode to configure the ARP timeout. The default timeout is 3,600 seconds. You can change it based on actual situations.

Configuring the ARP Request Retransmission Interval and Times

- Run the **arp retry interval** *seconds* command in global configuration mode to configure the ARP request retransmission interval. The default interval is 1 second. You can change it based on actual situations.
- Run the **arp retry times** *number* command in global configuration mode to configure the ARP request retransmission times. The default number of retransmission times is 5. You can change it based on actual situations.

Configuring the Maximum Number of Unresolved ARP Entries

Run the **arp unresolve** *number* command in global configuration mode to configure the maximum number of unresolved ARP entries. The default value is the maximum number of ARP entries supported by the device. You can change it based on actual situations.

Configuring the Maximum Number of ARP Entries on an Interface

Run the **arp cache interface-limit** *limit* command in interface configuration mode to configure the maximum number of ARP entries learned on an interface. The default number is 0. You can change it based on actual situations. This command also applies to static ARP entries.

Configuring the Maximum Number of ARP Entries on a Board

Run the **arp dynamic-entry-limit** *slot-id subslot-id limit* command in global configuration mode to configure the maximum number of ARP entries learned on a specified board. The default number is 0. You can change it based on actual situations.

2.3.3 Trusted ARP

Working Principle

As a type of special ARP entries, trusted ARP entries are added to the ARP table to prevent ARP spoofing. Trusted ARP entries have characteristics of both static and dynamic ARP entries, with a priority higher than that of dynamic ARP entries and lower than that of static ARP entries. Trusted ARP has an aging mechanism similar to that of dynamic ARP. When an ARP entry ages, the device actively sends an ARP request packet to detect whether the corresponding user exists. If the user sends a reply, the device regards the user active and updates the ARP timeout. Otherwise, the device deletes the ARP entry. Trusted ARP has characteristics of static ARP, that is, the device does not learn ARP packets to update the MAC address and interface ID in the ARP entry.

When a user goes online on a GSN client, the authentication server obtains the user's reliable IP-MAC mapping through the access switch, and adds trusted ARP entries to the user's gateway. This process is transparent to the network administrator and does not affect the administrator’s work on network management.

Since trusted ARP entries come from authentic sources and will not be updated, they can efficiently prevent ARP spoofing targeted at the gateway.

Related Configuration

Enabling Trusted ARP

- Run the **arp trusted user-vlan** *vid1* **translated-vlan** *vid2* command in global configuration mode to implement VLAN redirection. This function is disabled by default. If the VLAN pushed by the server differs from the VLAN in the trusted ARP entry, users need to enable VLAN redirection.
- Run the **arp trusted aging** command in global configuration mode to enable ARP aging. Trusted ARP entries are not aged by default.
- Run the **arp trusted number** command in global configuration mode to configure the capacity of trusted ARP entries. The default value is half of the total capacity of ARP entries. You can change it based on actual situations.

2.3.4 Gratuitous ARP

Working Principle

Gratuitous ARP packets are a special type of ARP packets. In a gratuitous ARP packet, the source and destination IP addresses are the IP address of the local device. Gratuitous ARP packets have two purposes:

5. IP address conflict detection. If the device receives a gratuitous packet and finds the IP address in the packet the same as its own IP address, it sends an ARP reply to notify the peer end of the IP address conflict.
6. ARP update. When the MAC address of an interface changes, the device sends a gratuitous ARP packet to notify other devices to update ARP entries.

The device can learn gratuitous ARP packets. After receiving a gratuitous ARP packet, the device checks whether the corresponding dynamic ARP entry exists. If yes, the device updates the ARP entry based on the information carried in the gratuitous ARP packet.

Related Configuration

↘ Enabling Gratuitous ARP

Run the **arp gratuitous-send interval** *seconds* [*number*] command in interface configuration mode to enable gratuitous ARP. This function is disabled on interfaces by default. Generally you need to enable this function on the gateway interface to periodically update the MAC address of the gateway on the downlink devices, which prevents others from faking the gateway.

2.3.5 Proxy ARP

Working Principle

The device enabled with Proxy ARP can help a host without any route information to obtain MAC addresses of IP users in other subnets. For example, if the device receiving an ARP request finds the source IP address in a different network segment from the destination IP address and knows the route to the destination address, the device sends an ARP reply containing its own Ethernet MAC address. This is how Proxy ARP works.

Related Configuration

↘ Enabling Proxy ARP

- Run the **ip proxy-arp** command in interface configuration mode to enable Proxy ARP.
- This function is enabled on routers while disabled on switches by default.

2.3.6 Local Proxy ARP

Working Principle

Local Proxy ARP means that a device acts as a proxy in the local VLAN (common VLAN or sub VLAN).

After local Proxy ARP is enabled, the device can help users to obtain the MAC addresses of other users in the same subnet. For example, when port protection is enabled on the device, users connected to different ports are isolated at Layer 2. After local Proxy ARP is enabled, the device receiving an ARP request acts as a proxy to send an ARP reply containing its own

Ethernet MAC address. In this case, different users communicate with each other through Layer-3 routes. This is how local Proxy ARP works.

Related Configuration

Enabling Local Proxy ARP

- Run the **local-proxy-arp** command in interface configuration mode to enable local Proxy ARP.
- This function is disabled by default.
- This command is supported only on switch virtual interfaces (SVIs).

2.3.7 ARP Trustworthiness Detection

Working Principle

The **arp trust-monitor enable** command is used to enable anti-ARP spoofing to prevent excessive useless ARP entries from occupying device resources. After ARP trustworthiness detection is enabled on a Layer-3 interface, the device receives ARP request packets from this interface:

1. If the corresponding entry does not exist, the device creates a dynamic ARP entry and performs NUD after 1 to 5 seconds. That is, the device begins to age the newly learned ARP entry and sends a unicast ARP request. If the device receives an ARP update packet from the peer end within the aging time, it stores the entry. If not, it deletes the entry.
2. If the corresponding ARP entry exists, NUD is not performed.
3. If the MAC address in the existing dynamic ARP entry is updated, the device also performs NUD.

Since this function adds a strict confirmation procedure in the ARP learning process, it affects the efficiency of ARP learning.

After this function is disabled, NUD is not required for learning and updating ARP entries.

Related Configuration

Enabling ARP Trustworthiness Detection

Run the **arp trust-monitor enable** command in interface configuration mode to enable ARP trustworthiness detection. This function is disabled by default.

2.3.8 Disabling Dynamic ARP Entry Learning

Working Principle

After dynamic ARP entry learning is disabled on an interface, this interface does not learn dynamic ARP entries.

Related Configuration

Disabling Dynamic ARP Entry Learning

- Dynamic ARP entry learning is enabled on interfaces by default.
- Run the **no arp-learning enable** command in interface configuration mode to disable dynamic ARP entry learning.

2.4 Configuration

Configuration	Description and Command	
Enabling Static ARP	(Optional) It is used to enable static IP-MAC binding.	
	arp	Enables static ARP.
Configuring ARP Attributes	(Optional) It is used to specify the ARP timeout, ARP request retransmission interval and times, maximum number of unresolved ARP entries, maximum number of ARP entries on an interface, and maximum number of ARP entries on a board.	
	arp timeout	Configures the ARP timeout.
	arp retry interval	Configures the ARP request retransmission interval.
	arp unresolve	Configures the maximum number of unresolved ARP entries.
	arp cache interface-limit	Configures the maximum number of ARP entries on an interface.
Enabling Trusted ARP	(Optional) It is used to enable anti-ARP spoofing.	
	arp trusted user-vlan	Enables VLAN redirection when a trusted ARP entry is added.
	arp trusted aging	Enables trusted ARP aging.
	arp trusted	Configures the capacity of trusted ARP entries.
Enabling Gratuitous ARP	(Optional) It is used to detect IP address conflicts and enables peripheral devices to update ARP entries.	
	arp gratuitous-send interval	Enables gratuitous ARP.
Enabling Proxy ARP	(Optional) It is used to act as a proxy to reply to ARP requests from the devices in different subnets.	
	ip proxy-arp	Enables Proxy ARP.
Enabling Local Proxy ARP	(Optional) It is used to act as a proxy to reply to ARP requests from other devices in the same subnet.	
	local-proxy-arp	Enables local Proxy ARP.
Enabling ARP Trustworthiness Detection	(Optional) It is used to unicast ARP request packets to ensure that correct ARP entries are learned.	
	arp trusted-monitor enable	Enables ARP trustworthiness detection.
Disabling Dynamic ARP	(Optional) It is used to disable dynamic ARP learning on an interface.	

Configuration	Description and Command	
Learning	**no arp-learning enable**	Disables dynamic ARP learning on an interface.

2.4.1 Enabling Static ARP

Configuration Effect

Users can manually specify IP-MAC mapping to prevent the device from learning incorrect ARP entries.

Notes

After a static ARP entry is configured, the Layer-3 switch learns the physical port corresponding to the MAC address in the static ARP entry before it performs Layer-3 routing.

Configuration Steps

↘ Configuring Static ARP Entries

- Optional.
- You can configure a static ARP entry to bind the IP address of the uplink device with its MAC address to prevent MAC change caused by ARP attacks.
- Configure static ARP entries in global configuration mode.

Verification

Run the **show running-config** command to check whether the configuration takes effect. Or run the **show arp static** command to check whether a static ARP cache table is created.

Related Commands

↘ Configuring Static ARP Entries

Command	**arp** *ip-address mac-address type*
Parameter Description	*ip-address*: Indicates the IP address mapped to a MAC address, which is in four-part dotted-decimal format. *mac-address*: Indicates the DLL address, consisting of 48 bits. *type*: Indicates the ARP encapsulation type. For an Ethernet interface, the keyword is **arpa**.
Command Mode	Global configuration mode
Usage Guide	The RGOS queries a 48-bit MAC address based on a 32-bit IP address in the ARP cache table. Since most hosts support dynamic ARP resolution, usually the static ARP mapping are not configured. Use the **clear arp-cache** command to delete the dynamic ARP entries.

Configuration Example

Scenario	For the network topology, see Figure 2-1.
Configuration	Configure a static ARP entry on B to statically bind the IP address of A with the MAC address.

Steps	Ruijie(config)#arp 192.168.23.1 00D0.F822.334B arpa
Verification	Run the **show arp static** command to display the static ARP entry. Ruijie(config)#show arp static Protocol Address Age(min) Hardware Type Interface Internet 192.168.23.1 <static> 00D0.F822.334B arpa 1 static arp entries exist.

Common Errors

- The MAC address in static ARP is incorrect.

2.4.2 Configuring ARP Attributes

Configuration Effect

Users can specify the ARP timeout, ARP request retransmission interval and times, maximum number of unresolved ARP entries, maximum number of ARP entries on an interface, and maximum number of ARP entries on a board.

Configuration Steps

Configuring the ARP Timeout

- Optional.
- In a LAN, if a user goes online/offline frequently, it is recommended to set the ARP timeout small to delete invalid ARP entries as soon as possible.
- Configure the ARP timeout in interface configuration mode.

Configuring the ARP Request Retransmission Interval and Times

- Optional.
- If the network resources are insufficient, it is recommended to set the ARP request retransmission interval great and the retransmission times small to reduce the consumption of network bandwidths.
- Configure the ARP request retransmission interval and times in global configuration mode.

Configuring the Maximum Number of Unresolved ARP Entries

- Optional.
- If the network resources are insufficient, it is recommended to set the maximum number of unresolved ARP entries small to reduce the consumption of network bandwidths.
- Configure the maximum number of unresolved ARP entries in global configuration mode.

Configuring the Maximum Number of ARP Entries on an Interface

- Optional.

- Configure the maximum number of ARP entries on an interface in interface configuration mode.

Configuring the Maximum Number of ARP Entries on a Board

- Optional.
- Configure the maximum number of ARP entries on a board in global configuration mode.

Verification

Run the **show arp timeout** command to display the timeouts of all interfaces.

Run the **show running-config** command to display the ARP request retransmission interval and times, maximum number of unresolved ARP entries, maximum number of ARP entries on an interface, and maximum number of ARP entries on a board.

Related Commands

Configuring the ARP Timeout

Command	**arp timeout** *seconds*
Parameter Description	*seconds*: Indicates the timeout in seconds, ranging from 0 to 2,147,483. The default value is 3,600.
Command Mode	Interface configuration mode
Usage Guide	The ARP timeout only applies to the dynamically learned IP-MAC mapping. When the ARP timeout is set to a smaller value, the mapping table stored in the ARP cache is more accurate but ARP consumes more network bandwidth. Unless otherwise specified, do not configure the ARP timeout.

Configuring the ARP Request Retransmission Interval and Times

Command	**arp retry interval** *seconds*
Parameter Description	*seconds*: Indicates the ARP request retransmission interval in seconds, ranging from 1 to 3,600. The default value is 1.
Command Mode	Global configuration mode
Usage Guide	If a device frequently sends ARP requests, affecting network performance, you can set the ARP request retransmission interval longer. Ensure that this interval does not exceed the ARP timeout.

Configuring the Maximum Number of Unresolved ARP Entries

Command	**arp unresolve** *number*
Parameter Description	*number*: Indicates the maximum number of unresolved ARP entries, ranging from 1 to 8,192. The default value is 8,192.
Command Mode	Global configuration mode
Usage Guide	If a large number of unresolved entries exist in the ARP cache table and remain in the table after a while, it is recommended to use this command to limit the number of unresolved ARP entries.

Configuring the Maximum Number of ARP Entries on an Interface

Command	**arp cache interface-limit** *limit*
Parameter Description	*limit*: Indicates the maximum number of ARP entries that can be learned on an interface, including configured ARP entries and dynamically learned ARP entries. The value ranges from 0 to the ARP entry capacity supported by the device. 0 indicates no limit on this number.
Command Mode	Interface configuration mode
Usage Guide	Limiting the number of ARP entries on an interface can prevent malicious ARP attacks from generating excessive ARP entries on the device and occupying entry resources. The configured value must be equal to or greater than the number of the ARP entries learned by the interface. Otherwise, the configuration does not take effect. The configuration is subject to the ARP entry capacity supported by the device.

Configuration Example

Scenario	For the network topology, see Figure 2-1.
Configuration Steps	● Set the ARP timeout to 60 seconds on port GigabitEthernet 0/1. ● Set the maximum number of learned ARP entries to 300 on port GigabitEthernet 0/1. ● Set the ARP request retransmission interval to 3 seconds. ● Set the ARP request retransmission times to 4. ● Set the maximum number of unresolved ARP entries to 4,096.
	`Ruijie(config)#interface gigabitEthernet 0/1` `Ruijie(config-if-GigabitEthernet 0/1)#arp timeout 60` `Ruijie(config-if-GigabitEthernet 0/1)#arp cache interface-limit 300` `Ruijie(config-if-GigabitEthernet 0/1)#exit` `Ruijie(config)#arp retry interval 3` `Ruijie(config)#arp retry times 4` `Ruijie(config)#arp unresolve 4096`
Verification	● Run the **show arp timeout** command to display the timeout of the interface. ● Run the **show running-config** command to display the ARP request retransmission interval and times, maximum number of unresolved ARP entries, maximum number of ARP entries on the interface, and maximum number of ARP entries on the board.
	`Ruijie#show arp timeout` `Interface arp timeout(sec)` `---------- ----------` `GigabitEthernet 0/1 60` `GigabitEthernet 0/2 3600` `GigabitEthernet 0/4 3600`

```
GigabitEthernet 0/5     3600
GigabitEthernet 0/7     3600
VLAN 100                3600
VLAN 111                3600
Mgmt 0                  3600

Ruijie(config)# show running-config
arp unresolve 4096
arp retry times 4
arp retry interval 3
!
interface GigabitEthernet 0/1
 arp cache interface-limit 300
```

2.4.3 Enabling Trusted ARP

Configuration Effect

The gateway is protected from ARP spoofing.

Notes

Configuration Steps

- To deploy a GSN solution, enable trusted ARP.
- To deploy a GSN solution, enable trusted ARP.
- Enable trusted ARP in global configuration mode.

Verification

Run the **show arp trusted** command to display trusted ARP entries.

Run the **show running** command to check whether the configuration takes effect.

Related Commands

↘ **Enabling VLAN Redirection When a Trusted ARP Entry Is Added**

Command	**arp trusted user-vlan** *vid1* **translated-vlan** *vid2*
Parameter	*vid1*: Indicates the VLAN ID configured on the server.

Description	*vid2*: Indicates the ID of the VLAN redirected.
Command Mode	Global configuration mode
Usage Guide	This command takes effect only after trusted ARP is enabled. Configure this command only when the VLAN pushed by the server differs from the VLAN in the trusted ARP entry.

Displaying Trusted ARP Entries

Command	**show arp trusted** [*ip* [*mask*]]
Parameter Description	*ip*: Indicates the IP address. The ARP entry of the specified IP address is displayed. If keyword **trusted** is specified, only the trusted ARP entries are displayed. Otherwise, the non-trusted ARP entries are displayed. *mask*: ARP entries within the IP subnet are displayed. If keyword **trusted** is specified, only the trusted ARP entries are displayed. Otherwise, the non-trusted ARP entries are displayed.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Deleting Trusted ARP Entries

Command	**clear arp trusted** [*ip* [*mask*]]
Parameter Description	*ip*: Indicates the IP address. The ARP entry of the specified IP address is displayed. If keyword **trusted** is specified, only the trusted ARP entries are displayed. Otherwise, the non-trusted ARP entries are displayed. *mask*: ARP entries within the IP subnet are displayed. If keyword **trusted** is specified, only the trusted ARP entries are displayed. Otherwise, the non-trusted ARP entries are displayed.
Command Mode	Privileged EXEC mode
Usage Guide	After you run the **clear arp trusted** command to delete all trusted ARP entries on the switch, users may fail to access the network. It is recommended to use the **clear arp trusted** *ip* command to delete a specified trusted ARP entry.

Enabling Trusted ARP Aging

Command	**arp trusted aging**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After you configure this command, trusted ARP entries begin to age, with the aging time the same as the dynamic ARP aging time. You can run the **arp timeout** command in interface configuration mode to configure the aging time.

Adjusting the Capacity of Trusted ARP Entries

Command	**arp trusted** *number*

Parameter Description	*number*: The minimum value is 10. The maximum number is the capacity supported by the device minus 1,024. By default, the maximum number of trusted ARP entries is half of the total capacity of ARP entries.
Command Mode	Privileged EXEC mode
Usage Guide	To make this command take effect, enable trusted ARP first. Trusted ARP entries and other entries share the memory. If trusted ARP entries occupy much space, dynamic ARP entries may not have sufficient space. Set the number of ARP entries based on the actual requirement. Do not set it to an excessively large value.

Configuration Example

Scenario	For the network topology, see Figure 2-1.
Configuration Steps	● Enable VLAN redirection. ● Enable trusted ARP aging. ● Set the maximum number of trusted ARP entries to 1,024.
	Ruijie(config)#arp trusted user-vlan 2-9 translated-vlan 10 Ruijie(config)#arp trusted aging Ruijie(config)#arp trusted 1024
Verification	● Run the **show running-config** command to check whether the configurations take effect.
	Ruijie(config)# show running-config arp trusted user-vlan 2-9 translated-vlan 10 arp trusted aging arp trusted 1024

Common Errors

- Trusted ARP is disabled, causing failure to assign ARP entries.

2.4.4 Enabling Gratuitous ARP

Configuration Effect

The interface periodically sends gratuitous ARP packets.

Configuration Steps

- Optional.
- When a switch acts as the gateway, enable gratuitous ARP on an interface to prevent other users from learning incorrect gateway MAC address in case of ARP spoofing.
- Enable gratuitous ARP in interface configuration mode.

Verification

Run the **show running-config interface** <*name*> command to check whether the configuration is successful.

Related Commands

Enabling Gratuitous ARP

Command	**arp gratuitous-send interval** *seconds* [*number*]
Parameter Description	*seconds*: Indicates the interval for sending a gratuitous ARP request. The unit is second. The value ranges from 1 to 3,600. *number*: Indicates the number of gratuitous ARP requests that are sent. The default value is 1. The value ranges from 1 to 100.
Command Mode	Interface configuration mode
Usage Guide	If a network interface of a device acts as the gateway for downstream devices but a downstream device pretends to be the gateway, enable gratuitous ARP on the interface to advertise itself as the real gateway.

Configuration Example

Scenario	For the network topology, see Figure 2-1.
Configuration Steps	Configure the GigabitEthernet 0/0 interface to send a gratuitous ARP packet every 5 seconds.
	`Ruijie(config-if-GigabitEthernet 0/0)#arp gratuitous-send interval 5`
Verification	Run the **show running-config interface** command to check whether the configuration takes effect.
	`Ruijie#sh running-config interface gigabitEthernet 0/0` `Building configuration...` `Current configuration : 127 bytes` `!` `interface GigabitEthernet 0/0` ` duplex auto` ` speed auto` ` ip address 30.1.1.1 255.255.255.0` ` arp gratuitous-send interval 5`

2.4.5 Enabling Proxy ARP

Configuration Effect

The device acts as a proxy to reply to ARP request packets from other users.

Notes

By default, Proxy ARP is disabled on Layer-3 switches while enabled on routers.

Configuration Steps

- Optional.
- If a user without any route information needs to obtain the MAC addresses of the IP users in other subnets, enable Proxy ARP on the device so that the device can act as a proxy to send ARP replies.
- Enable Proxy ARP in interface configuration mode.

Verification

Run the **show ip interface** <*name*> command to check whether the configuration takes effect.

Related Commands

Enabling Proxy ARP

Command	**ip proxy-arp**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Scenario	For the network topology, see Figure 2-1.
Configuration Steps	Enable Proxy ARP on port GigabitEthernet 0/0 .
	`Ruijie(config-if-GigabitEthernet 0/0)#ip proxy-arp`
Verification	Run the **show ip interface** command to check whether the configuration takes effect.
	`Ruijie#show ip interface gigabitEthernet 0/0` `GigabitEthernet 0/0` `  IP interface state is: DOWN` `  IP interface type is: BROADCAST` `  IP interface MTU is: 1500` `  IP address is:` `    No address configured` `  IP address negotiate is: OFF` `  Forward direct-broadcast is: OFF`

```
  ICMP mask reply is: ON
  Send ICMP redirect is: ON
  Send ICMP unreachable is: ON
  DHCP relay is: OFF
  Fast switch is: ON
  Help address is: 0.0.0.0
  Proxy ARP is: ON
ARP packet input number: 0
  Request packet     : 0

 Echo reply         : 0
 Unreachable        : 0
 Source quench      : 0
 Routing redirect   : 0
```

2.4.6 Enabling Local Proxy ARP

Configuration Effect

The device acts as a proxy to reply to ARP request packets from other users in the same subnet.

Notes

Local Proxy ARP is supported only on SVIs.

Configuration Steps

- Optional.
- If a user enabled with port protection needs to communicate with users in the VLAN, enable local Proxy ARP on the device.
- Enable local Proxy ARP in interface configuration mode.

Verification

Run the **show run interface** <*name*> command to check whether the configuration takes effect.

Related Commands

Enabling Local Proxy ARP

Command	**local-proxy-arp**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Scenario	For the network topology, see Figure 2-1.
Configuration Steps	Enable local Proxy ARP on the VLAN 1 interface.
	`Ruijie(config-if-VLAN 1)#local-proxy-arp`
Verification	Run the **show ip interface** command to check whether the configuration takes effect.
	`Ruijie#show running-config interface vlan 1` `Building configuration...` `Current configuration : 53 bytes` `interface VLAN 1` ` ip address 192.168.1.2 255.255.255.0` ` local-proxy-arp`

2.4.7 Enabling ARP Trustworthiness Detection

Configuration Effect

Enable ARP trustworthiness detection. If the device receiving an ARP request packet fails to find the corresponding entry, it performs NUD. If the MAC address in the existing dynamic ARP entry is updated, the device immediately performs NUD to prevent ARP attacks.

Notes

Since this function adds a strict confirmation procedure in the ARP learning process, it affects the efficiency of ARP learning.

Configuration Steps

- Optional.
- If there is a need for learning ARP entries, enable ARP trustworthiness detection on the device. If the device receiving an ARP request packet fails to find the corresponding entry, it needs to send a unicast ARP request packet to check whether the peer end exists. If yes, the device learns the ARP entry. If not, the device does not learn the ARP entry. If the MAC address in the ARP entry changes, the device will immediately perform NUD to prevent ARP spoofing.
- Enable ARP trustworthiness detection in interface configuration mode.

Verification

Run the **show running-config interface** <*name*> command to check whether the configuration take effect

Related Commands

Enabling ARP Trustworthiness Detection

Command	**arp trust-monitor enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Enable this function. If the corresponding ARP entry exists and the MAC address is not updated, the device does not perform NUD. Enable this function. If the MAC address of the existing dynamic ARP entry is updated, the device immediately performs NUD. After this function is disabled, the device does not perform NUD for learning or updating ARP entries.

Configuration Example

Scenario	For the network topology, see Figure 2-1.
Configuration Steps	Enable ARP trustworthiness detection on port GigabitEthernet 0/0.
	`Ruijie(config-if-GigabitEthernet 0/0)#arp trust-monitor enable`
Verification	Run the **show running-config interface** command to check whether the configuration takes effect.
	`Ruijie#show running-config interface gigabitEthernet 0/0` `Building configuration...` `Current configuration : 184 bytes` `!` `interface GigabitEthernet 0/0`

	duplex auto speed auto ip address 30.1.1.1 255.255.255.0 arp trust-monitor enable

2.4.8 Disabling Dynamic ARP Learning

Configuration Effect

After dynamic ARP learning is disabled on an interface, the interface does not learn dynamic ARP entries.

Configuration Steps

- Optional.
- Enable dynamic ARP learning in interface configuration mode.

Verification

Run the **show running-config interface** <*name*> command to check whether the configuration takes effect.

Related Commands

Disabling Dynamic ARP Learning

Command	**no arp-learning enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	If the device has learned the dynamic ARP entries and converted the ARP entries into static ARP entries through Web, disable dynamic ARP learning. Otherwise, enable dynamic ARP learning. After this function is enabled, users can convert dynamic ARP entries into static ARP entries through Web. Users can also use the **clear arp** command to clear ARP entries to deny a user Internet access. If the **clear arp** command is not configured, dynamic ARP entries will be cleared when the timeout expires. After the dynamic ARP learning function is disabled on an interface, the any IP ARP and ARP trustworthiness detection functions will not work.

Configuration Example

Scenario	For the network topology, see Figure 2-1.
Configuration Steps	Disable dynamic ARP entry learning on port GigabitEthernet 0/0.
	Ruijie(config-if-GigabitEthernet 0/0)#no arp-learning enable
Verification	Run the **show running-config interface** command to check whether the configuration takes effect.

```
Ruijie#sh running-config interface gigabitEthernet 0/0

Building configuration...
Current configuration : 127 bytes
!
interface GigabitEthernet 0/0
 duplex auto
 speed auto
 ip address 30.1.1.1 255.255.255.0
 no arp-learning enable
```

2.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears dynamic ARP entries. In gateway authentication mode, dynamic ARP entries in authentication VLANs are not cleared.	**clear arp-cache**

Displaying

Description	Command
Displays the ARP table.	**show ip arp**
Displays the trusted ARP table.	**show arp trusted** [*ip* [*mask*]]
Displays the ARP entry counter.	**show arp counter**
Displays the timeout of dynamic ARP entries.	**show arp timeout**

Debugging

System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Description	Command
Debugs ARP packet sending and	**debug arp**

receiving.	
Debugs the creation and deletion of ARP entries.	**debug arp event**

3 Configuring IPv6

3.1 Overview

As the Internet develops rapidly and IPv4 address space is becoming exhausted, IPv4 limitations become more and more obvious. At present, many researches and practices on Internet Protocol Next Generation (IPng) have been conducted. The IPng working group of the Internet Engineering Task Force (IETF) has formulated an IPng protocol named IP Version 6 (IPv6), which is described in RFC 2460.

Main Features

Larger Address Space

Compared with 32 bits in an IPv4 address, the length of an IPv6 address is extended to 128 bits. Therefore, the address space has approximately 2^{128} addresses. IPv6 adopts a hierarchical address allocation mode to support address allocation of multiple subnets from the Internet core network to intranet subnet.

Simpler Packet Header Format

Since the design principle of the IPv6 packet header is to minimize the overhead of the packet header, some non-key fields and optional fields are removed from the packet header to the extended packet header. Therefore, although the length of an IPv6 address is four times of that of an IPv4 address, the IPv6 packet header is only two times of the IPv4 packet header. The IPv6 packet header makes device forwarding more efficient. For example, with no checksum in the IPv6 packet header, the IPv6 device does not need to process fragments (fragmentation is completed by the initiator).

Efficient Hierarchical Addressing and Routing Structure

IPv6 uses a convergence mechanism and defines a flexible hierarchical addressing and routing structure. Multiple networks at the same layer are represented as a uniform network prefix on the upstream device, greatly reducing routing entries maintained by the device and routing and storage overheads of the device.

Easy Management: Plug and Play (PnP)

IPv6 provides automatic discovery and auto-configuration functions to simplify management and maintenance of network nodes. For example, Neighbor Discovery (ND), MTU Discovery, Router Advertisement (RA), Router Solicitation (RS), and auto-configuration technologies provide related services for PnP. Particularly, IPv6 offers two types of auto-configuration: stateful auto-configuration and stateless auto-configuration. In IPv4, Dynamic Host Configuration Protocol (DHCP) realizes auto-configuration of the host IP address and related parameters. IPv6 inherits this auto-configuration service from IPv4 and called it stateful auto-configuration (see DHCPv6). Besides, IPv6 also offers the stateless auto-configuration service.During stateless auto-configuration, a host automatically obtains the local address of the link, address prefix of the local device, and other related configurations.

Security

As an optional extension protocol of IPv4, Internet Protocol Security (IPSec) is a part of IPv6 to provide security for IPv6 packets. At present, IPv6 provides two mechanisms: Authentication Header (AH) and Encapsulated Security Payload (ESP). AH provides data integrity and authenticates IP packet sources to ensure that the packets originate from the nodes identified by the source addresses. ESP provides data encryption to realize end-to-end encryption.

Better QoS Support

A new field in the IPv6 packet header defines how to identify and process data streams. The Flow Label field in the IPv6 packet header is used to authenticate a data flow. Using this field, IPv6 allows users to propose requirements on the communication quality. , A device can identify all packets belonging to a specific data stream based on this field and process these packets according to user requirements.

New Protocol for Neighboring Node Interaction

IPv6 Neighbor Discovery Protocol (NDP) uses a series of Internet Control Message Protocol Version 6 (ICMPv6) packets to implement interactive management of neighboring nodes (nodes on the same link). IPv6 uses NDP packets and efficient multicast/unicast ND packets instead of broadcast-based Address Resolution Protocol (ARP) and Control Message Protocol Version 4 (ICMPv4) router discovery packets.

Extensibility

With strong extensibility, IPv6 features can be added to the extended packet header following the IPv6 packet header. Unlike IPv4, the IPv6 packet header can support at most 40 bytes of options. For an IPv6 packet, the length of the extended packet header is restricted only by the maximum number of bytes in the packet.

Protocols and Standards

- RFC 4291 - IP Version 6 Addressing Architecture
- RFC 2460 - Internet Protocol, Version 6 (IPv6) Specification
- RFC 4443 - Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification
- RFC 4861 - Neighbor Discovery for IP version 6 (IPv6)
- RFC 4862 - IPv6 Stateless Address Auto-configuration
- RFC 5059 - Deprecation of Type 0 Routing Headers in IPv6

3.2 Applications

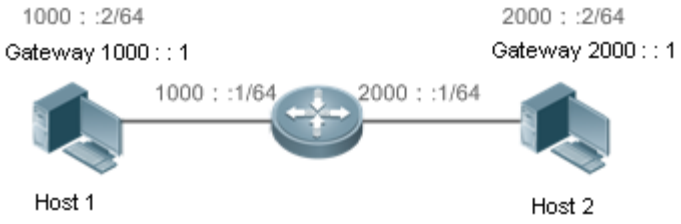
Application	Description
Communication Based on IPv6 Addresses	Two PCs communicate with each other using IPv6 addresses.

3.2.1 Communication Based on IPv6 Addresses

Scenario

As shown in Figure 3-1, Host 1 and Host 2 communicate with each other using IPv6 addresses.

Figure 3-1



Deployment

Hosts can use the stateless address auto-configuration or DHCPv6 address assignment mode. After addresses are configured, hosts can communicate with each other using IPv6 addresses.

3.3 Features

Overview

Feature	Description
IPv6 Address Format	The IPv6 address format makes IPv6 have a larger address space and flexible representation approach.
IPv6 Address Type	IPv6 identifies network applications based on addresses.
IPv6 Packet Header Format	IPv6 simplifies the fixed and extended packet headers to improve the data packet processing and forwarding efficiency of the device.
IPv6 PMTUD	A host dynamically discovers and adjusts the MTU size on the data Tx path, saving router resources and improving IPv6 network efficiency.
IPv6 Neighbor Discovery	ND functions include router discovery, prefix discovery, parameter discovery, address auto-configuration, address resolution (like ARP), next-hop determination, Neighbor Unreachability Detection (NUD), Duplicate Address Detection (DAD), and redirection.
IPv6 Source Routing	This feature is used to specify the intermediate nodes that a packet passes through along the path to the destination address. It is similar to the IPv4 loose source routing option and loose record routing option.
Restricting the Sending Rate of ICMPv6 Error Messages	This feature prevents DoS attacks.
IPv6 HOP-LIMIT	This feature prevents useless unicast packets from being unlimitedly transmitted on the network and wasting network bandwidth.

Feature	Description
Default Gateway on the Management Interface	The default gateway is configured on the management interface to generate a default route for this interface.

3.3.1 IPv6 Address Format

An IPv6 address is represented in the X:X:X:X:X:X:X:X format, where X is a 4-digit hexadecimal integer (16 bits). Each address consists of 8 integers, with a total of 128 bits (each integer contains 4 hexadecimal digits and each digit contains four bits). The following are three valid IPv6 addresses:

2001:ABCD:1234:5678:AAAA:BBBB:1200:2100

800:0:0:0:0:0:0:1

1080:0:0:0:8:800:200C:417A

These integers are hexadecimal, where A to F represent 10 to 15. Each integer in the address must be represented, except the leading zeros in each integer. If an IPv6 address contains a string of zeros (as shown in the second and third examples above), a double colon (::) can be used to represent these zeros. That is, 800:0:0:0:0:0:0:1 can be represented as 800::1.

A double colon indicates that this address can be extended to a complete 128-bit address. In this approach, only when the 16-bit integers are all 0s, can they can be replaced with a double colon. A double colon can exist once in an IPv6 address.

In IPv4/IPv6 mixed environment, an address has a mixed representation. In an IPv6 address, the least significant 32 bits can be used to represent an IPv4 address. This IPv6 address can be represented in a mixed manner, that is, X:X:X:X:X:X:d.d.d.d, where X is a hexadecimal integer and d is a 8-bit decimal integer. For example, 0:0:0:0:0:0:192.168.20.1 is a valid IPv6 address. It can be abbreviated to :::192.168.20.1. Typical applications are IPv4-compatible IPv6 addresses and IPv4-mapped IPv6 addresses. If the first 96 bits are 0 in an IPv4-compatible IPv6 address, this address can be represented as ::A.B.C.D, e.g., ::1.1.1.1. IPv4-compatible addresses have been abolished at present. IPv4-mapped IPv6 addresses are represented as ::FFFF:A.B.C.D to represent IPv4 addresses as IPv6 addresses. For example, IPv4 address 1.1.1.1 mapped to an IPv6 address is represented as ::FFFF:1.1.1.1.

Since an IPv6 address is divided into two parts: subnet prefix and interface ID, it can be represented as an address with an additional value according to an address allocation method like Classless Inter-Domain Routing (CIDR). The additional value indicates how many bits (subnet prefix) in the address represent the network part. That is, the IPv6 node address contains the prefix length. The prefix length is separated from the IPv6 address by a slash. For example, in 12AB::CD30:0:0:0:0/60, the prefix length used for routing is 60 bits.

Related Configuration

↘ Configuring an IPv6 Address

- No IPv6 address is configured on interfaces by default.
- Run the **ipv6 address** command to configure an IPv6 address on an interface.
- After configuration, a host can communicate with others using the configured IPv6 address based on DAD.

3.3.2 IPv6 Address Type

RFC 4291 defines three types of IPv6 addresses:

- Unicast address: ID of a single interface. Packets destined to a unicast address are sent to the interface identified by this address.
- Multicast address: ID of an interface group (the interfaces generally belong to different nodes). Packets destined to a multicast address are sent to all interfaces included in this address.
- Anycast address: ID of an interface group. Packets destined to an anycast address are sent to one interface included in this address (the nearest interface according to the routing protocol).

⚠ IPv6 does not define broadcast addresses.

These three types of addresses are described as follows:

Unicast Addresses

Unicast addresses fall into five types: unspecified address, loopback address, link-local address, site-local address, and global unicast address. At present, site-local addresses have been abolished. Except unspecified, loopback, and link-local addresses, all other addresses are global unicast addresses.

- Unspecified address

The unspecified address is 0:0:0:0:0:0:0:0, which is usually abbreviated to ::. It has two general purposes:

1. If a host has no unicast address when started, it uses the unspecified address as the source address to send an RS packet to obtain prefix information from the gateway and thereby generate a unicast address.
2. When an IPv6 address is configured for a host, the device detects whether the address conflicts with addresses of other hosts in the same network segment and uses the unspecified address as the source address to send a Neighbor Solicitation (NS) packet (similar to a free ARP packet).

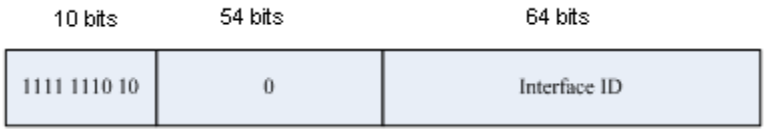
- Loopback address

The loopback address is 0:0:0:0:0:0:0:1, which is usually abbreviated to ::1. Similar to IPv4 address 127.0.0.1, the loopback address is generally used by a node to send itself packets.

- Link-local address

The format of a link-local address is as follows:

Figure 3-2

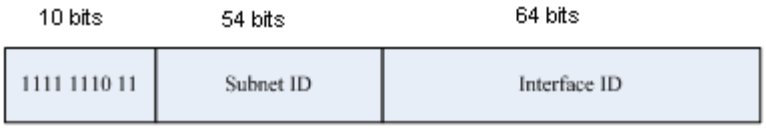


The link-local address is used on a single network link to assign IDs to hosts. The address identified by the first 10 bits in the prefix is the link-local address. A device never forwards packets in which the source or destination address contains the link-local address. The intermediate 54 bits in the address are all 0s. The last 64 bits represent the interface ID, which allows a single network to connect 2^{64}-1 hosts.

- Site-local address

The format of a site-local address is as follows:

Figure 3-3

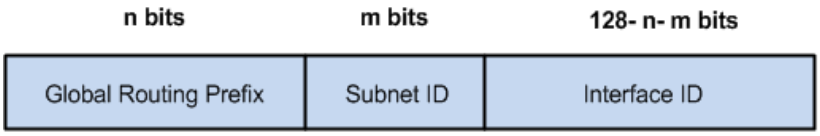


A site-local address is used to transmit data within a site. A device never forwards packets in which the source or destination address contains the site-local address to the Internet. That is, these packets can be forwarded only within the site. A site can be assumed as an enterprise's local area network (LAN). Such addresses are similar to IPv4 private addresses such as 192.168.0.0/16. RFC 3879 has abolished site-local addresses. New addresses do not support the first 10 bits as the prefix and are all regarded as global unicast addresses. Existing addresses can continue to use this prefix.

- Global unicast address

The format of a global unicast address is as follows:

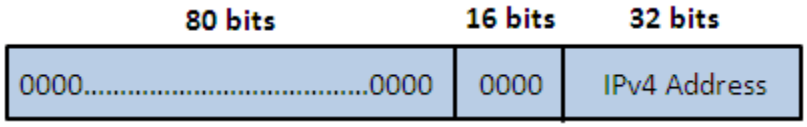
Figure 3-4



Among global unicast addresses, there is a type of IPv4-embedded IPv6 addresses, including IPv4-compatible IPv6 addresses and IPv4-mapped IPv6 addresses. They are used for interconnection between IPv4 nodes and IPv6 nodes.

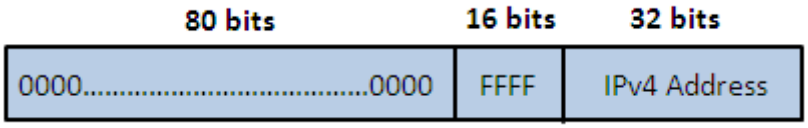
The format of an IPv4-compatible IPv6 address is as follows:

Figure 3-5



The format of an IPv4-mapped IPv6 address is as follows:

Figure 3-6



IPv4-compatible IPv6 addresses are mainly used on automatic tunnels. Nodes on automatic tunnels support both IPv4 and IPv6. Using these addresses, IPv4 devices transmit IPv6 packets over tunnels. At present, IPv4-compatible IPv6 addresses have been abolished. IPv4-mapped IPv6 addresses are used by IPv6 nodes to access IPv4-only nodes. For example, if the

IPv6 application on an IPv4/IPv6 host requests to resolve the name of an IPv4-only host, the name server dynamically generates an IPv4-mapped IPv6 address and returns it to the IPv6 application.

↘ Multicast Addresses

The format of an IPv6 multicast address is as follows:

```
|    8     |  4 |  4 |                   112 bits                   |
+--------+----+----+----------------------------------------------+
|11111111|flgs|scop|                    group ID                    |
+--------+----+----+----------------------------------------------+
```

The first byte in the address is all 1s, representing a multicast address.

- Flag field

The flag field consists of four bits. Currently only the fourth bit is specified to indicate whether this address is a known multicast address assigned by the Internet Assigned Numbers Authority (IANA) or a temporary multicast address in a certain scenario. If the flag bit is 0, this address is a known multicast address. If the flag bit is 1, this address is a temporary multicast address. The remaining three flag bits are reserved for future use.

- Scope field

The scope field consists of four bits to indicate the multicast range. That is, a multicast group includes the local node, local link, local site, and any node in the IPv6 global address space.

- Group ID field

The group ID consists of 112 bits to identify a multicast group. A multicast ID can represent different groups based on the flag and scope fields.

IPv6 multicast addresses are prefixed with FF00::/8. One IPv6 multicast address usually identifies interfaces on a series of different nodes. After a packet is sent to a multicast address, the packet is then forwarded to the interfaces on each node identified by this multicast address. For a node (host or device), you must add the following multicast addresses:

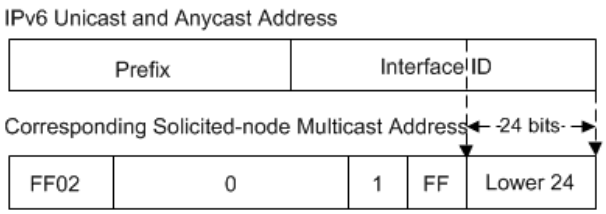
3. Multicast address for all nodes on the local link, that is, FF02::1
4. Solicited-node multicast address, prefixed with FF02:0:0:0:0:1:FF00:0000/104

If the node is a device, it also has to be added to the multicast address of all devices on the local link, that is, FF02::2.

The solicited-node multicast address corresponds to the IPv6 unicast and anycast address. You must add a corresponding solicited-node multicast address for each configured unicast and anycast address of an IPv6 node. The solicited-node multicast address is prefixed with FF02:0:0:0:0:1:FF00:0000/104. The remaining 24 bits are composed of the least significant 24 bits of the unicast or anycast address. For example, if the unicast address is FE80::2AA:FF:FE21:1234, the solicited-node multicast address is FF02::1:FF21:1234.

The solicited-node multicast address is usually used in NS packets. Its address format is as follows:

Figure 3-7



Anycast Addresses

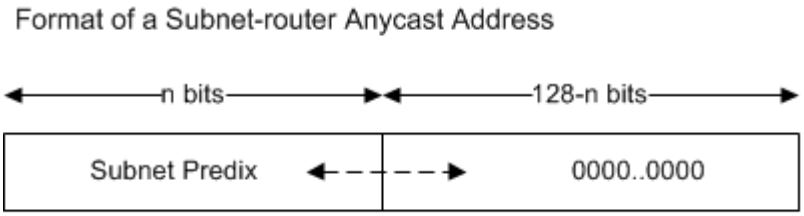
Similar to a multicast address, an anycast address can also be shared by multiple nodes. The difference is that only one node in the anycast address receives data packets while all nodes included in the multicast address receive data packets. Since anycast addresses are allocated to the normal IPv6 unicast address space, they have the same formats with unicast addresses. Every member in an anycast address must be configured explicitly for easier recognition.

Anycast addresses can be allocated only to devices and cannot be used as source addresses of packets.

RFC 2373 redefines an anycast address called subnet-router anycast address. Figure 3-8 shows the format of a subnet-router anycast address. Such an address consists of the subnet prefix and a series of 0s (interface ID).

The subnet prefix identifies a specified link (subnet). Packets destined to the subnet-router anycast address will be forwarded to a device on this subnet. A subnet-router anycast address is usually used by the application on a node to communicate with a device on a remote subnet.

Figure 3-8



Related Configuration

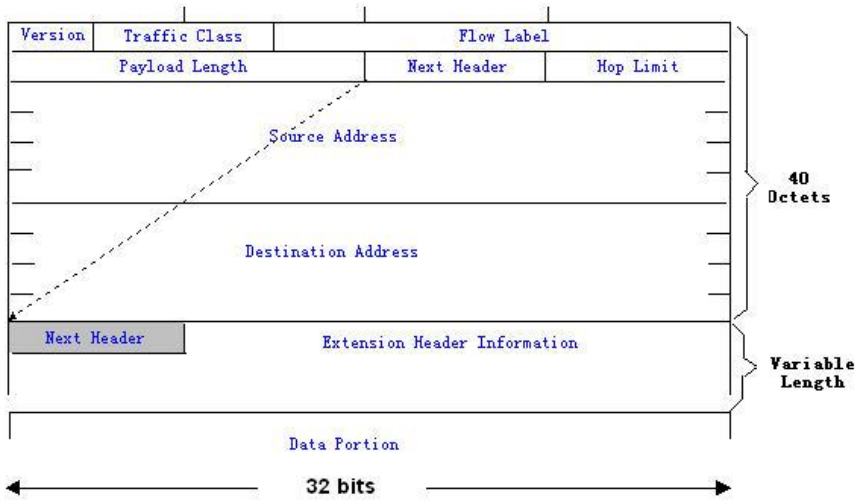
Configuring an IPv6 Address

- No IPv6 address is configured on interfaces by default.
- Run the **ipv6 address** command to configure the IPv6 unicast address and anycast address of an interface.
- After an interface goes up, it will automatically join the corresponding multicast group.

3.3.3 IPv6 Packet Header Format

Figure 3-9 shows the format of the IPv6 packet header.

Figure 3-9



The IPv4 packet header is in unit of four bytes. The IPv6 packet header consists of 40 bytes, in unit of eight bytes. The IPv6 packet header has the following fields:

- Version

This field consists of 4 bits. In an IPv6 address, this field must be 6.

- Traffic Class

This field consists of 8 bits. This field indicates the service provided by this packet, similar to the TOS field in an IPv4 address.

- Flow Label

This field consists of 20 bits to identify packets belonging to the same service flow. One node can act as the Tx source of multiple service flows. The flow label and source address uniquely identify one service flow.

- Payload Length

This field consists of 16 bits, including the packet payload length and the length of IPv6 extended options (if available). That is, it includes the IPv6 packet length except the IPv6 packet header.

- Next Header

This field indicates the protocol type in the header field following the IPv6 packet header. Similar to the Protocol field in the IPv4 address header, the Next Header field is used to indicate whether the upper layer uses TCP or UDP. It can also be used to indicate existence of the IPv6 extension header.

- Hop Limit

This field consists of 8 bits. Every time a device forwards a packet, the field value reduced by 1. If the field value reaches 0, this packet will be discarded. It is similar to the Lifetime field in the IPv4 packet header.

- Source Address

This field consists of 128 bits and indicates the sender address in an IPv6 packet.

- Destination Address

This field consists of 128 bits and indicates the receiver address in an IPv6 packet.

At present, IPv6 defines the following extension headers:

- Hop-By-Hop Options

This extension header must follow the IPv6 packet header. It consists of option data to be checked on each node along the path.

- Routing Options (Type 0 routing header)

This extension header indicates the nodes that a packet passes through from the source address to the destination address. It consists of the address list of the passerby nodes. The initial destination address in the IPv6 packet header is the first address among the addresses in the routing header, but not the final destination address of the packet. After the node corresponding to the destination address in the IPv6 packet header receives a packet, it processes the IPv6 packet header and routing header, and sends the packet to the second address, the third address, and so on in the routing header list till the packet reaches the final destination address.

- Fragment

The source node uses this extension header to fragment the packets of which the length exceeds the path MTU (PMTU).

- Destination Options

This extension header replaces the option fields of IPv4. At present, the Destination Options field can only be filled with integral multiples of 64 bits (eight bytes) if required. This extension header can be used to carry information to be checked by the destination node.

- Upper-layer header

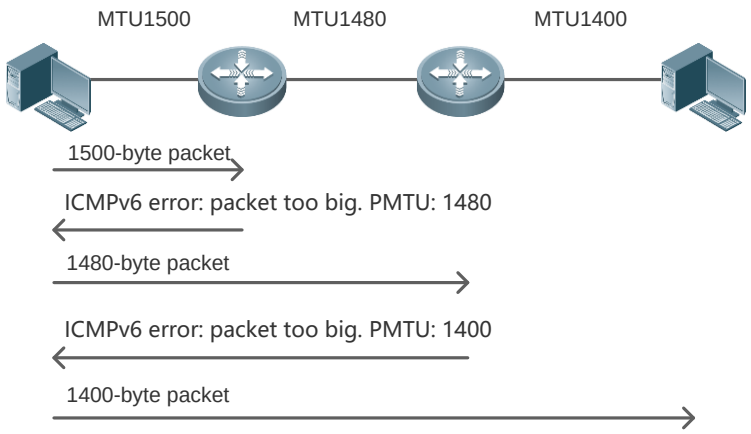
This extension header indicates the protocol used at the upper layer, such as TCP (6) and UDP (17).

Another two extension headers AH and ESP will be described in the *Configuring IPSec*.

3.3.4 IPv6 PMTUD

Similar to IPv4 Path MTU Discovery (PMTUD), IPv6 PMTUD allows a host to dynamically discover and adjust the MTU size on the data Tx path. If the length of a data packet to be sent by a host is greater than the PMTU, the host performs packet fragmentation on its own. In this manner, the IPv6 device does not need to perform fragmentation, saving device resources and improving the IPv6 network efficiency.

Figure 3-10



As shown in Figure 3-10, if the length of a packet to be sent by the host is greater than the PMTU, the router discards this packet and sends an ICMPv6 Packet Too Big message containing its PMTU to the host. The host then fragments the packet based on the new PMTU. In this manner, the router does not need to perform fragmentation, saving router resources and improving the IPv6 network efficiency.

Related Configuration

Configuring the IPv6 MTU of an Interface

- The default IPv6 MTU is 1500 on an Ethernet interface.
- Run the **ipv6 mtu** command to modify the IPv6 MTU of an interface.

3.3.5 IPv6 Neighbor Discovery

NDP is a basic part of IPv6. Its main functions include router discovery, prefix discovery, parameter discovery, address auto-configuration, address resolution (like ARP), next-hop determination, NUD, DAD, and redirection. NDP defines five ICMP packets: RS (ICMP type: 133), RA (ICMP type: 134), NS (similar to ARP request, ICMP type: 135), NA (similar to ARP reply, ICMP type: 136), ICMP Redirect (ICMP type: 137).

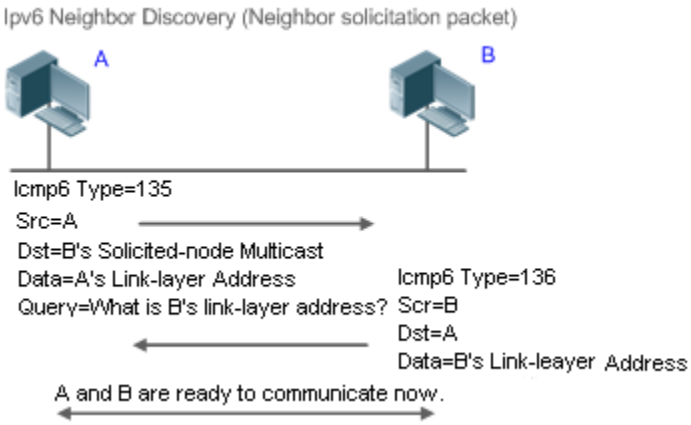
All the above ICMP packets carry one or multiple options. These options are optional in some cases but are significant in other cases. NDP mainly defines five options: Source Link-Layer Address Option, Type=1; Target Link-Layer Address Option, Type=2; Prefix Information Option, Type=3; Redirection Header Option, Type=4; MTU Option, Type=5.

Address Resolution

When a node attempts to communicate with another, the node has to obtain the link-layer address of the peer end by sending it an NS packet. In this packet, the destination address is the solicited-node multicast address corresponding to the IPv6 address of the destination node. This packet also contains the link-layer address of the source node. After receiving this NS packet, the peer end replies with an NA packet in which the destination address is the source address of the NS packet, that is, the link-layer address of the solicited node. After receiving this NA packet, the source node can communicate with the destination node.

Figure 3-11 shows the address resolution process.

Figure 3-11



NUD

If the reachable time of a neighbor has elapsed but an IPv6 unicast packet needs to be sent to it, the device performs NUD.

While performing NUD, the device can continue to forward IPv6 packets to the neighbor.

DAD

To know whether the IPv6 address configured for a host is unique, the device needs to perform DAD by sending an NS packet in which the source IPv6 address is the unspecified address.

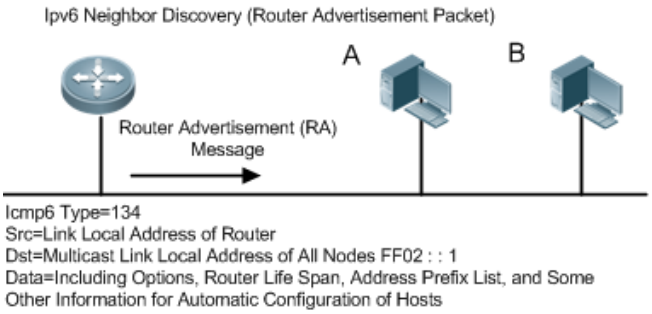
If a device detects an address conflict, this address is set to the duplicate status so that the device cannot receive IPv6 packets with this address being the destination address. Meanwhile, the device also starts a timer for this duplicate address to periodically perform DAD. If no address conflict is detected in re-detection, this address can be properly used.

Router, Prefix, and Parameter Discovery

A device periodically sends RA packets to all local nodes on the link.

Figure 3-12 shows the RA packet sending process.

Figure 3-12



An RA packet usually contains the following content:

- One or multiple IPv6 address prefixes (used for on-link determination or stateless address auto-configuration)
- Validity of the IPv6 address prefix

- Host auto-configuration method (stateful or stateless)
- Default device information (whether the device acts as the default device; if yes, the interval for acting as the default device is also included.)
- Other information provided for host configuration, such as hop limit, MTU, and NS retransmission interval

RA packets can also be used as replies to the RS packets sent by a host. Using RS packets, a host can obtain the auto-configured information immediately after started rather than wait for the RA packets sent by the device. If no unicast address is configured for a newly started host, the host includes the unspecified address (0:0:0:0:0:0:0:0) as the source address in the RS packet. Otherwise, the host uses the configured unicast address as the source address and the multicast address of all local routing devices (FF02::2) as the destination address in the RS packet. As an reply to the RS packet, the RA packet uses the source address of the RS packet as the destination address (if the source address is the unspecified address, it uses the multicast address of all local nodes (FF02::1).

In an RA packet, the following parameters can be configured:

- Ra-interval: Interval for sending the RA packet.
- Ra-lifetime: Lifetime of a router, that is, whether the device acts as the default router on the local link and the interval for acting as the default router.
- Prefix: Prefix of an IPv6 address on the local link. It is used for on-link determination or stateless address auto-configuration, including other parameter configurations related to the prefix.
- Ns-interval: NS packet retransmission interval.
- Reachabletime: Period when the device regards a neighbor reachable after detecting a Confirm Neighbor Reachability event.
- Ra-hoplimit: Hops of the RA packet, used to set the hop limit for a host to send a unicast packet.
- Ra-mtu: MTU of the RA packet.
- Managed-config-flag: Whether a host receiving this RA packet obtains the address through stateful auto-configuration.
- Other-config-flag: Whether a host receiving this RA packet uses DHCPv6 to obtain other information except the IPv6 address for auto-configuration.

Configure the above parameters when configuring IPv6 interface attributes.

Redirection

If a router receiving an IPv6 packet finds a better next hop, it sends the ICMP Redirect packet to inform the host of the better next hop. The host will directly send the IPv6 packet to the better next hop next time.

Maximum Number of Unresolved ND Entries

- You can configure the maximum number of unresolved ND entries to prevent malicious scanning network segments from generating a large number of unresolved ND entries and occupying excessive memory space.

Maximum Number of ND Options

- You can configure the maximum number of ND options to prevent forged ND packets from carrying unlimited ND options and occupying excessive CPU space on the device.

Maximum Number of Neighbor Learning Entries on an Interface

- You can configure the maximum number of neighbor learning entries on an interface to prevent neighbor learning attacks from occupying ND entries and memory space of the device and affecting forwarding efficiency of the device.

Related Configuration

Enabling IPv6 Redirection

- By default, ICMPv6 Redirect packets can be sent on IPv6 interfaces.
- Run the **no ipv6 redirects** command in interface configuration mode to prohibit an interface from sending Redirect packets.

Configuring IPv6 DAD

- By default, an interface sends one NS packet to perform IPv6 DAD.
- Run the **ipv6 nd dad attempts** *value* command in interface configuration mode to configure the number of NS packets consecutively sent by DAD. Value 0 indicates disabling DAD for IPv6 addresses on this interface.
- Run the **no ipv6 nd dad attempts** command to restore the default configuration.
- By default, the device performs DAD on duplicate IPv6 addresses every 60 seconds.
- Run the **ipv6 nd dad retry** value command in global configuration mode to configure the DAD interval. Value 0 indicates disabling DAD for the device.
- Run the **no ipv6 nd dad retry** command to restore the default configuration.

Configuring the Reachable Time of a Neighbor

- The default reachable time of an IPv6 neighbor is 30s.
- Run the **ipv6 nd reachable-time** *milliseconds* command in interface configuration mode to modify the reachable time of a neighbor.

Configuring the Stale Time of a Neighbor

- The default stale time of an IPv6 neighbor is 1 hour. After the time elapses, the device performs NUD.
- Run the **ipv6 nd stale-time** *seconds* command in interface configuration mode to modify the stale time of a neighbor.

Configuring Prefix Information

- By default, the prefix in an RA packet on an interface is the prefix configured in the **ipv6 address** command on the interface.
- Run the **ipv6 nd prefix** command in interface configuration mode to add or delete prefixes and prefix parameters that can be advertised.

Enabling/disabling RA Suppression

- By default, an IPv6 interface does not send RA packets.
- Run the **no ipv6 nd suppress-ra** command in interface configuration mode to disable RA suppression.

Configuring the Maximum Number of Unresolved ND Entries

- The default value is 0, indicating no restriction. It is only restricted to the ND entry capacity supported by the device.
- Run the **ipv6 nd unresolved** *number* command in global configuration mode to restrict the number of unresolved neighbors. After the entries exceed this restriction, the device does not actively resolve subsequent packets.

Configuring the Maximum Number of ND Entries Learned on an Interface

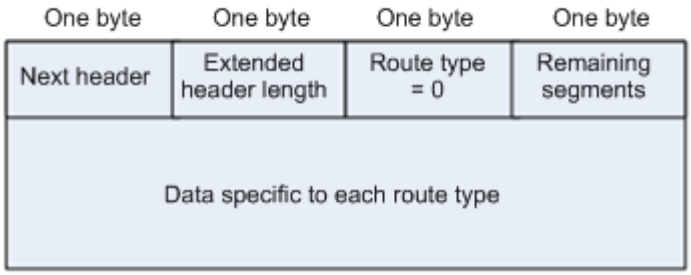
- Run the **ipv6 nd cache interface-limit** *value* command in interface configuration mode to restrict the number of neighbors learned on an interface. The default value is 0, indicating no restriction.

3.3.6 IPv6 Source Routing

Working Principle

Similar to the IPv4 loose source routing and loose record routing options, the IPv6 routing header is used to specify the intermediate nodes that the packet passes through along the path to the destination address. It uses the following format:

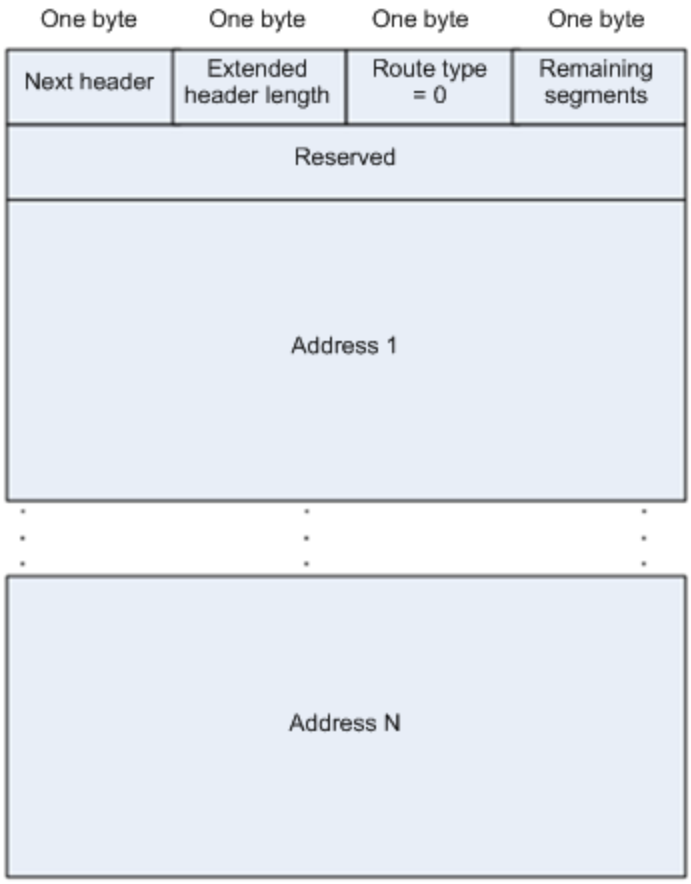
Figure 3-13



The Segments Left field is used to indicate how many intermediate nodes are specified in the routing header for the packet to pass through from the current node to the final destination address.

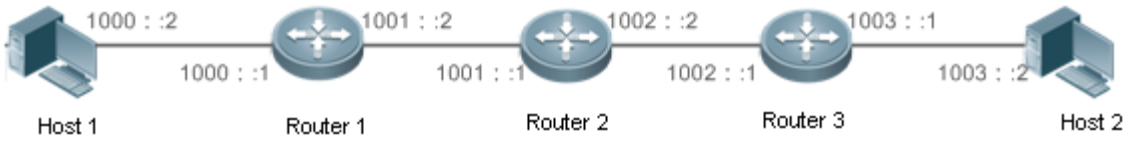
Currently, two routing types are defined: 0 and 2. The Type 2 routing header is used for mobile communication. RFC 2460 defines the Type 0 routing header (similar to the loose source routing option of IPv4). The format of the Type 0 routing header is as follows:

Figure 3-14



The following example describes the application of the Type 0 routing header, as shown in Figure 3-15.

Figure 3-15



Host 1 sends Host 2 a packet specifying the intermediate nodes Router 2 and Router 3. The following table lists the changes of fields related to the IPv6 header and routing header during the forwarding process.

Transmission Node	Fields in the IPv6 Header	Fields Related to the Type 0 Routing Header
Host 1	Source address=1000::2 Destination address=1001::1 (Address of Router 2)	Segments Left=2 Address 1=1002::1 (Address of Router 3) Address 2=1003::2 (Address of Host 2)
Router 1	No change	
Router 2	Source address=1000::2 Destination address=1002::1 (Address of Router 3)	Segments Left=1 Address 1=1001::1 (Address of Router 2) Address 2=1003::2 (Address of Host 2)

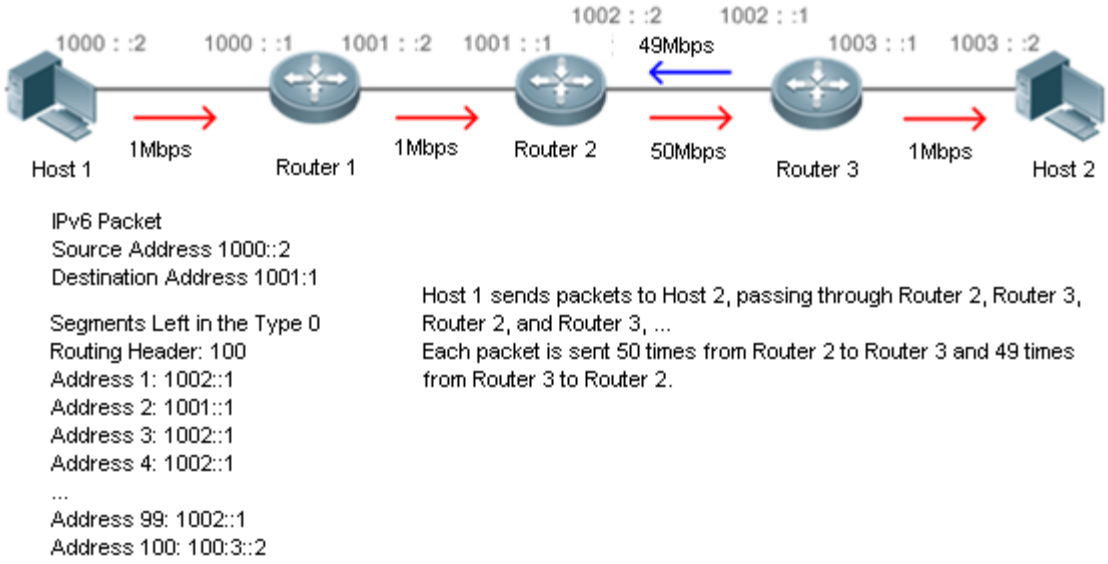
Router 3	Source address=1000::2 Destination address=1003::2 (Address of Host 2)	Segments Left=0 Address 1=1001::1 (Address of Router 2) Address 1=1002::2 (Address of Router 3)
Host 2	No change	

The forwarding process is as follows:

5. Host 1 sends a packet in which the destination address is Router 2's address 1001::1, the Type 0 routing header is filled with Router 3's address 1002::1 and Host 2's address 1003::2, and the value of the Segments Left field is 2.
6. Router 1 forwards this packet to Router 2.
7. Router 2 changes the destination address in the IPv6 header to Address 1 in the routing header. That is, the destination address becomes Router 3's address 1002::1, Address 1 in the routing header becomes Router 2's address 1001::1, and the value of the Segments Left field becomes 1. After modification, Router 2 forwards the packet to Router 3.
8. Router 3 changes the destination address in the IPv6 header to Address 2 in the routing header. That is, the destination address becomes Host 2's address 1003::2, Address 2 in the routing header becomes Router 3's address 1002::1, and the value of the Segments Left field becomes 0. After modification, Router 3 forwards the packet to Host 2.

The Type 0 routing header may be used to initiate DoS attacks. As shown in Figure 3-16, Host 1 sends packets to Host 2 at 1 Mbps and forges a routing header to cause multiple round-trips between Router 2 and Router 3 (50 times from Router 2 to Router 3 and 49 times from Router 3 to Router 2). At the time, the routing header generates the traffic amplification effect:" 50 Mbps from Router 2 to Router 3 and 49 Mbps from Router 3 to Router 2." Due to this security problem, RFC 5095 abolished the Type 0 routing header.

Figure 3-16



Related Configuration

Enabling IPv6 Source Routing

- The Type 0 routing header is not supported by default.
- Run the **ipv6 source-route** command in global configuration mode to enable IPv6 source routing.

3.3.7 Restricting the Sending Rate of ICMPv6 Error Messages

Working Principle

The destination node or intermediate router sends ICMPv6 error messages to report the errors incurred during IPv6 data packet forwarding and transmission. There are mainly four types of error messages: Destination Unreachable, Packet Too Big, Time Exceeded, and Parameter Problem.

When receiving an invalid IPv6 packet, a device discards the packet and sends back an ICMPv6 error message to the source IPv6 address. In the case of invalid IPv6 packet attacks, the device may continuously reply to ICMPv6 error messages till device resources are exhausted and thereby fail to properly provide services. To solve this problem, you can restrict the sending rate of ICMPv6 error messages.

If the length of an IPv6 packet to be forwarded exceeds the IPv6 MTU of the outbound interface, the router discards this IPv6 packet and sends back an ICMPv6 Packet Too Big message to the source IPv6 address. This error message is mainly used as part of the IPv6 PMTUD process. If the sending rate of ICMPv6 error messages is restricted due to excessive other ICMPv6 error messages, ICMPv6 Packet Too Big messages may be filtered, causing failure of IPv6 PMTUD. Therefore, it is recommended to restrict the sending rate of ICMPv6 Packet Too Big messages independently of other ICMPv6 error messages.

Although ICMPv6 Redirect packets are not ICMPv6 error messages, Ruijie recommends restricting their rates together with ICMPv6 error messages except Packet Too Big messages.

Related Configuration

Configuring the Sending Rate of ICMPv6 Packet Too Big Messages

- The default rate is 10 per 100 ms.
- Run the **ipv6 icmp error-interval too-big** command to configure the sending rate of ICMPv6 Packet Too Big messages.

Configuring the Sending Rate of Other ICMPv6 Error Messages

- The default rate is 10 per 100 ms.
- Run the **ipv6 icmp error-interval** command to configure the sending rate of other ICMPv6 error messages.

3.3.8 IPv6 Hop Limit

Working Principle

An IPv6 data packet passes through routers from the source address and destination address. If a hop limit is configured, it decreases by one every time the packet passes through a router. When the hop limit decreases to 0, the router discards the packet to prevent this useless packet from being unlimitedly transmitted on the network and wasting network bandwidth. The hop limit is similar to the TTL of IPv4.

Related Configuration

Configuring the IPv6 Hop Limit

- The default IPv6 hop limit of a device is 64.
- Run the **ipv6 hop-limit** command to configure the IPv6 hop limit of a device.

3.3.9 Default Gateway on the Management Interface

Working Principle

The default gateway is configured on the management interface to generate a default route for this interface.

Related Configuration

Configuring the Default Gateway on the Management Interface

- Run the **ipv6 gateway** *ipv6-address* command in interface configuration mode to configure the default gateway on the management interface.
- No default gateway is configured on the management interface by default.

3.4 Configuration

Configuration	Description and Command	
Configuring an IPv6 Address	(Mandatory) It is used to configure IPv6 addresses and enable IPv6.	
	ipv6 enable	Enables IPv6 on an interface.
	ipv6 address	Configures the IPv6 unicast address of an interface.
Configuring IPv6 NDP	(Optional) It is used to enable IPv6 redirection on an interface.	
	ipv6 redirects	Enables IPv6 redirection on an interface.
	(Optional) It is used to enable DAD.	
	ipv6 nd dad attempts	Configures the number of consecutive NS packets sent during DAD.
	(Optional) It is used to configure ND parameters.	
	ipv6 nd reachable-time	Configures the reachable time of a neighbor.
	ipv6 nd prefix	Configures the address prefix to be advertised in an RA packet.
	ipv6 nd suppress-ra	Enables RA suppression on an interface.
	(Optional) It is used to configure the maximum number of unresolved ND entries.	
	ipv6 nd unresolved	Configures the maximum number of unresolved ND entries.

Configuration	Description and Command	
	(Optional) It is used to configure the maximum number of neighbors learned on an interface.	
	ipv6 nd cache interface-limit	Configures the maximum number of neighbors learned on an interface.
Enabling PMTUD	(Optional) It is used to restrict the MTU of IPv6 packets sent on an interface.	
	ipv6 mtu	Configures the IPv6 MTU.
Enabling IPv6 Source Routing	(Optional) It is used to enable IPv6 source routing.	
	ipv6 source-route	Configures the device to forward IPv6 packets carrying the routing header.
Configuring the Sending Rate of ICMPv6 Error Messages	Optional.	
	ipv6 icmp error-interval too-big	Configures the sending rate of ICMPv6 Packet Too Big messages.
	ipv6 icmp error-interval	Configures the sending rates of other ICMPv6 error messages and ICMPv6 Redirect packets.
Configuring the IPv6 Hop Limit	(Optional) It is used to restrict the hop limit of IPv6 unicast packets sent on an interface.	
	ipv6 hop-limit	Configures the IPv6 hop limit.
Configuring the Default Gateway on the Management Interface	(Optional) It is used to configure the default gateway on the management interface.	
	ipv6 gateway *ipv6-address*	Configures the default gateway on the management interface.

3.4.1 Configuring an IPv6 Address

Configuration Effect

Configure the IPv6 address of an interface to implement IPv6 network communication.

Configuration Steps

Enabling IPv6 on an Interface

- (Optional) If you do not want to enable IPv6 by configuring an IPv6 address, run the **ipv6 enable** command.

Configuring the IPv6 Unicast Address of an Interface

- Mandatory.

Verification

Run the **show ipv6 interface** command to check whether the configured address takes effect.

Related Commands

Enabling IPv6 on an Interface

Command	**ipv6 enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	IPv6 can be enabled on an interface by two methods: 1) running the **ipv6 enable** command in interface configuration mode; 2) configuring an IPv6 address on the interface. If an IPv6 address is configured on an interface, IPv6 is automatically enabled on this interface. In this case, IPv6 cannot be disabled even when you run the **no ipv6 enable** command.

Configuring the IPv6 Unicast Address of an Interface

Command	**ipv6 address** *ipv6-address* / *prefix-length* **ipv6 address** *ipv6-prefix* / *prefix-length* **eui-64** **ipv6 address** *prefix-name sub-bits* / *prefix-length* [**eui-64**]
Parameter Description	*ipv6-address*: Indicates the IPv6 address, which must comply with the address format defined in RFC 4291. Separated by a colon (:), each address field consists of 16 bits and is represented by hexadecimal digits. *ipv6-prefix*: Indicates the IPv6 address prefix, which must comply with the address format defined in RFC 4291. *prefix-length*: Indicates the length of the IPv6 address prefix, that is, the part representing the network in the IPv6 address. *prefix-name*: Indicates the name of the universal prefix. This specified universal prefix is used to create the interface address. *sub-bits*: Indicates the subprefix bits and host bits of the address to be concatenated with the prefixes provided by the general prefix specified with the *prefix-name* parameter. This value is combined with the universal prefix to create the interface address. This value must be in the form documented in RFC 4291. *eui-64*: Indicates the created IPv6 address, consisting of the configured address prefix and 64-bit interface ID.
Command Mode	Interface configuration mode
Usage Guide	If an IPv6 interface is created and is Up state, the system automatically generates a link-local address for this interface. The IPv6 address of an interface can also be created by the universal prefix mechanism. That is, IPv6 address = Universal prefix + Sub prefix + Host bits. The universal prefix can be configured by running the **ipv6 general-prefix** command or learned by the prefix discovery function of the DHCPv6 client (see the *Configuring DHCPv6*). Sub prefix + Host bits are specified by the *sub-bits* and *prefix-length* parameters in the **ipv6 address** command. If you run the **no ipv6 address** command without specifying an address, all manually configured addresses will be deleted.

	Run the **no ipv6 address** *ipv6-prefix/prefix-length* **eui-64** command to delete the configured address.

Configuration Example

Configuring an IPv6 Address on an Interface

Configuration Steps	Enable IPv6 on the GigabitEthernet 0/0 interface and add IPv6 address 2000::1 to the interface.
	Ruijie(config)#interface gigabitEthernet 0/0 Ruijie(config-if-GigabitEthernet 0/0)#ipv6 enable Ruijie(config-if-GigabitEthernet 0/0)#ipv6 address 2000::1/64
Verification	Run the **show ipv6 interface** command to verify that an address is successfully added to the GigabitEthernet 0/0 interface.
	Ruijie(config-if-GigabitEthernet 0/0)#show ipv6 interface gigabitEthernet 0/0 interface GigabitEthernet 0/0 is Down, ifindex: 1, vrf_id 0 address(es): Mac Address: 00:00:00:00:00:00 INET6: FE80::200:FF:FE00:1 [TENTATIVE], subnet is FE80::/64 INET6: 2000::1 [TENTATIVE], subnet is 2000::/64 Joined group address(es): MTU is 1500 bytes ICMP error messages limited to one every 100 milliseconds ICMP redirects are enabled ND DAD is enabled, number of DAD attempts: 1 ND reachable time is 30000 milliseconds ND advertised reachable time is 0 milliseconds ND retransmit interval is 1000 milliseconds ND advertised retransmit interval is 0 milliseconds ND router advertisements are sent every 200 seconds<160--240> ND router advertisements live for 1800 seconds

3.4.2 Configuring IPv6 NDP

Configuration Effect

Configure NDP-related attributes, for example, enable IPv6 redirection and DAD.

Notes

RA suppression is enabled on interfaces by default. To configure a device to send RA packets, run the **no ipv6 nd suppress-ra** command in interface configuration mode.

Configuration Steps

Enabling IPv6 Redirection on an Interface

- (Optional) IPv6 redirection is enabled by default.
- To disable IPv6 redirection on an interface, run the **no ipv6 redirects** command.

Configuring the Number of Consecutive NS Packets Sent During DAD

- Optional.
- To prevent enabling DAD for IPv6 addresses on an interface or modify the number of consecutive NS packets sent during DAD, run the **ipv6 nd dad attempts** command.

Configuring the Reachable Time of a Neighbor

- Optional.
- To modify the reachable time of a neighbor, run the **ipv6 nd reachable-time** command.

Configuring the Address Prefix to Be Advertised in an RA Packet

- By default, the prefix in an RA packet on an interface is the prefix configured in the **ipv6 address** command on the interface.
- (Optional) Run the **ipv6 nd prefix** command to add or delete prefixes and prefix parameters that can be advertised. Or run the **peer default ipv6 pool** command to assign a prefix from the prefix pool for advertisement

Enabling/Disabling RA Suppression on an Interface

- Optional.
- If a device needs to send RA packets, run the **no ipv6 nd suppress-ra** command.

Configuring the Maximum Number of Unresolved ND Entries

- Optional.
- If a large number of unresolved ND entries are generated due to scanning attacks, run the **ipv6 nd unresolved** command to restrict the number of unresolved neighbors.

Configuring the Maximum Number of ND Options

- Optional.
- If a device needs to process more options, run the **ipv6 nd max-opt** command.

Configuring the Maximum Number of ND Entries Learned on an Interface

- Optional.
- If the number of IPv6 hosts is controllable, run the **ipv6 nd cache interface-limit** command to restrict the number of neighbors learned on an interface. This prevents ND learning attacks from occupying the memory space and affecting device performance.

Verification

Run the following commands to check whether the configuration is correct:

- **show ipv6 interface** *interface-type interface-num*: Check whether the configurations such as the redirection function, reachable time of a neighbor, and NS sending interval take effect.
- **show ipv6 interface** *interface-type interface-num* **ra-inifo**: Check whether the prefix and other information configured for RA packets are correct.
- **show run**

Related Commands

Enabling IPv6 Redirection on an Interface

Command	**ipv6 redirects**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	All ICMPv6 error messages are transmitted at a limited transmission rate. By default, a maximum number of 10 ICMPv6 error messages are transmitted per second (10 pps).

Configuring the Number of Consecutive NS Packets Sent During DAD

Command	**ipv6 nd dad attempts** *value*
Parameter Description	*value*: Indicates the number of NS packets.
Command Mode	Interface configuration mode
Usage Guide	You need to enable DAD before configuring an IPv6 address on an interface. Then the address is in tentative state. If no address conflict is detected by DAD, this address can be correctly used. If an address conflict is detected and the interface ID of this address uses EUI-64, duplicate link-layer addresses exist on this link. In this case, the system automatically disables this interface to prevent IPv6-related operations on this interface). At the time, you must configure a new address and restart the interface to re-enable DAD. When an interface changes from the down state to the up state, DAD is re-enabled for the addresses on this interface.

Configuring the Reachable Time of a Neighbor

Command	**ipv6 nd reachable-time** *milliseconds*

Parameter Description	*milliseconds*: Indicates the reachable time of a neighbor, ranging from 0 to 3,600,000. The unit is millisecond. The default value is 30s.
Command Mode	Interface configuration mode
Usage Guide	A device detects unreachable neighbors based on the configured reachable time. The shorter the configured reachable time, the faster the device detects unreachable neighbors but the more it consumes network bandwidth and device resources. Therefore, it is not recommended to set this time too small. The configured value is advertised in an RA packet and is also used on the device. If the value is 0, the reachable time is not specified on the device and it is recommended to use the default value.

Configuring the Address Prefix to Be Advertised in an RA Packet

Command	**ipv6 nd prefix {***ipv6-prefix*/*prefix-length* | **default**} [[*valid-lifetime* { **infinite** | *preferred-lifetime* }] | [**at** *valid-date preferred-date*] | [**infinite** {**infinite** | *preferred-lifetime*}]] [**no-advertise**] | [[**off-link**] [**no-autoconfig**]]
Parameter Description	*ipv6-prefix*: Indicates the network ID of IPv6, which must comply with the address representation format in RFC 4291. *prefix-length*: Indicates the length of the IPv6 address prefix. A slash (/) must be added before the prefix. *valid-lifetime*: Indicates the period when a host receiving the prefix of an RA packet regards the prefix valid. The value ranges from 0 to 4,294,967,295. The default value is 30 days. *preferred-lifetime*: Indicates the preferred period when a host receiving the prefix of an RA packet regards the prefix valid. The value ranges from 0 to 4,294,967,295. The default value is 7 days. **at** *valid-date preferred-date*: Indicates the valid date and preferred deadline configured for the RA prefix. It uses the format of *dd+mm+yyyy+hh+mm*. **infinite**: Indicates that the prefix is permanently valid. **default**: Indicates that the default parameter configuration is used. **no-advertise**: Indicates that the prefix is not advertised by a router. **off-link**: If the prefix of the destination address in the IPv6 packet sent by a host matches the configured prefix, the device regards the destination address on the same link and directly reachable. This parameter indicates that this prefix does not require on-link determination. **no-autoconfig**: Indicates that the prefix in the RA packet received by a host cannot be used for address auto-configuration.
Command Mode	Interface configuration mode
Usage Guide	This command can be used to configure parameters related to each prefix, including whether to advertise this prefix. By default, an RA packet uses the prefix configured by running the **ipv6 address** command. Run the **ipv6 nd prefix** command to add other prefixes. Run the **ipv6 nd prefix default** command to configure the default parameters for an interface. That is, if no parameter is specified when a prefix is added, use the parameters configured in the **ipv6 nd prefix default** command as the parameters of the new prefix. The default parameter configurations are abandoned once a parameter is specified for the prefix. That is, when you use the **ipv6 nd prefix default** command to modify the default parameter configurations, only the prefix configured for the default parameters changes and

	configurations of the prefix remain the same. **at** *valid-date preferred-date*: You can specify the valid date of the prefix in two methods: 1) specifying a fixed time for each prefix in an RA packet; 2) specifying the deadline. In the second method, the valid date of the prefix in each RA packet decreases till it becomes 0.

Enabling/Disabling RA Suppression on an Interface

Command	**ipv6 nd suppress-ra**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	To enable RA suppression on an interface, run the **ipv6 suppress-ra** command.

Configuring the Maximum Number of Unresolved ND Entries

Command	**ipv6 nd unresolved** *number*
Parameter Description	*number*: Indicates the maximum number of unresolved ND entries.
Command Mode	Global configuration mode
Usage Guide	To prevent malicious scanning attacks from creating a large number of unresolved ND entries and occupying entry resources, you can restrict the number of unresolved ND entries.

Configuring the Maximum Number of ND Entries Learned on an Interface

Command	**ipv6 nd cache interface-limit** *value*
Parameter Description	*value*: Indicates the maximum number of neighbors learned by an interface.
Command Mode	Interface configuration mode
Usage Guide	Restricting the number of ND entries learned on an interface can prevent malicious neighbor attacks. If this number is not restricted, a large number of ND entries will be generated on the device, occupying excessive memory space. The configured value must be equal to or greater than the number of the ND entries learned by the interface. Otherwise, the configuration does not take effect. The configuration is subject to the ND entry capacity supported by the device.

Configuration Example

Enabling IPv6 Redirection on an Interface

Configuration Steps	Enable IPv6 redirection on interface GigabitEthernet 0/0.
	`Ruijie(config-if-GigabitEthernet 0/0)#ipv6 redirects`

Verification	Run the **show ipv6 interface** command to check whether the configuration takes effect.
	Ruijie#show ipv6 interface gigabitEthernet 0/0 interface GigabitEthernet 0/0 is Down, ifindex: 1, vrf_id 0 address(es): Mac Address: 00:00:00:00:00:00 INET6: FE80::200:FF:FE00:1 [TENTATIVE], subnet is FE80::/64 Joined group address(es): MTU is 1500 bytes ICMP error messages limited to one every 100 milliseconds ICMP redirects are enabled ND DAD is enabled, number of DAD attempts: 1 ND reachable time is 30000 milliseconds ND advertised reachable time is 0 milliseconds ND retransmit interval is 1000 milliseconds ND advertised retransmit interval is 0 milliseconds ND router advertisements are sent every 200 seconds<160--240> ND router advertisements live for 1800 seconds

Configuring IPv6 DAD

Configuration Steps	Configure the interface to send three consecutive NS packets during DAD.
	Ruijie(config-if-GigabitEthernet 0/0)# ipv6 nd dad attempts 3
Verification	Run the **show ipv6 interface** command to check whether the configuration takes effect.
	Ruijie#show ipv6 interface gigabitEthernet 0/0 interface GigabitEthernet 0/0 is Down, ifindex: 1, vrf_id 0 address(es): Mac Address: 00:00:00:00:00:00 INET6: FE80::200:FF:FE00:1 [TENTATIVE], subnet is FE80::/64 Joined group address(es): MTU is 1500 bytes

```
  ICMP error messages limited to one every 100 milliseconds
  ICMP redirects are enabled
  ND DAD is enabled, number of DAD attempts: 3
  ND reachable time is 30000 milliseconds
  ND advertised reachable time is 0 milliseconds
  ND retransmit interval is 1000 milliseconds
  ND advertised retransmit interval is 0 milliseconds
  ND router advertisements are sent every 200 seconds<160--240>
  ND router advertisements live for 1800 seconds
Ruijie(config-if-GigabitEthernet 0/0)#
```

Configuring Prefix Information in an RA Packet

Configuration Steps	Add a prefix 1234::/64 to interface GigabitEthernet 0/0.
	`Ruijie(config-if-GigabitEthernet 0/0)#ipv6 nd prefix 1234::/6`
Verification	Run the **show ipv6 interface** command to check whether the configuration takes effect.
	`Ruijie#show ipv6 interface gigabitEthernet 0/0 ra-info` `GigabitEthernet 0/0: DOWN (RA is suppressed)` `  RA timer is stopped` `  waits: 0, initcount: 0` `  statistics: RA(out/in/inconsistent): 0/0/0, RS(input): 0` `  Link-layer address: 00:00:00:00:00:00` `  Physical MTU: 1500` `  ND router advertisements live for 1800 seconds` `  ND router advertisements are sent every 200 seconds<160--240>` `  Flags: !M!O, Adv MTU: 1500` `  ND advertised reachable time is 0 milliseconds` `  ND advertised retransmit time is 0 milliseconds` `  ND advertised CurHopLimit is 64` `  Prefixes: <total: 1>` `    1234::/64(Def, CFG, vltime: 2592000, pltime: 604800, flags: LA)`

Configuring RA Packets to Obtain Prefixes from the Prefix Pool

Configuration Steps	Configure RA packets to obtain prefixes from the prefix pool "ra-pool".
	`Ruijie(config-if-GigabitEthernet 0/0)#peel default ipv6 pool ra-pool`
Verification	Run the **show run** command to check whether the configuration takes effect.
	`Ruijie(config-if-GigabitEthernet 0/0)#show run interface gigabitEthernet 0/0` `Building configuration...` `Current configuration : 125 bytes` `interface GigabitEthernet 0/0` ` ipv6 enable` ` no ipv6 nd suppress-ra` `peel default ipv6 pool ra-pool` `!`

Disabling RA Suppression

Configuration Steps	Disable RA suppression on an interface.
	`Ruijie(config-if-GigabitEthernet 0/0)# no ipv6 nd suppress-ra`
Verification	Run the **show run** command to check whether the configuration takes effect.
	`Ruijie(config-if-GigabitEthernet 0/0)#show run interface gigabitEthernet 0/0` `Building configuration...` `Current configuration : 125 bytes` `interface GigabitEthernet 0/0` ` ipv6 enable` ` no ipv6 nd suppress-ra` `!`

Configuring the Maximum Number of Unresolved ND Entries

Configuration Steps	Set the maximum number of unresolved ND entries to 200.
	`Ruijie(config)# ipv6 nd unresolved 200`
Verification	Run the **show run** command to check whether the configuration takes effect.
	`Ruijie#show run` `ipv6 nd unresolved 200` `!`

Configuring the Maximum Number of ND Entries Learned on an Interface

Configuration Steps	Set the maximum number of ND entries learned on an interface to 100.
	`Ruijie(config-if-GigabitEthernet 0/1)# ipv6 nd cache interface-limit 100`
Verification	Run the **show run** command to check whether the configuration takes effect.
	`Ruijie#show run` `!` `interface GigabitEthernet 0/1` `ipv6 nd cache interface-limit 100` `!`

3.4.3 Enabling PMTUD

Configuration Effect

When sending an IPv6 packet, a host fragments the packet based on the PMTU.

Notes

The IPv6 MTU of an interface must be less than or equal to the interface MTU.

Configuration Steps

Configuring the IPv6 MTU of an Interface

- Optional.

Verification

- Run the **show run** command to check whether the configuration is correct.

- Run the **show ipv6 interface** command to check whether the IPv6 MTU of an interface is correct.
- Capture the locally sent IPv6 packets of which the length exceeds the PMTU. The packet capture result shows that the IPv6 packet is fragmented based on the PMTU.

Related Commands

Configuring the IPv6 MTU of an Interface

Command	**ipv6 mtu** *bytes*
Parameter Description	*bytes*: Indicates the MTU of an IPv6 packet, ranging from 1280 to 1500. The unit is byte.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuring the IPv6 MTU of an Interface

Configuration Steps	Change the IPv6 MTU of interface GigabitEthernet 0/0 to 1,300.
	`Ruijie(config-if-GigabitEthernet 0/0)#ipv6 mtu 1300`
Verification	Run the **show ipv6 interface** command to check whether the configuration takes effect.
	`Ruijie(config-if-GigabitEthernet 0/0)#show ipv6 interface` `interface GigabitEthernet 0/ is Down, ifindex: 1, vrf_id 0` `  address(es):` `    Mac Address: 00:d0:f8:22:33:47` `    INET6: FE80::2D0:F8FF:FE22:3347 [ TENTATIVE ], subnet is FE80::/64` `    INET6: 1020::1 [ TENTATIVE ], subnet is 1020::/64` `    INET6: 1023::1 [ TENTATIVE ], subnet is 1023::/64` `  Joined group address(es):` `  MTU is 1300 bytes` `  ICMP error messages limited to one every 100 milliseconds` `  ICMP redirects are enabled` `  ND DAD is enabled, number of DAD attempts: 1` `  ND reachable time is 30000 milliseconds` `  ND advertised reachable time is 0 milliseconds`

Configuration Steps	Change the IPv6 MTU of interface GigabitEthernet 0/0 to 1,300.
	`Ruijie(config-if-GigabitEthernet 0/0)#ipv6 mtu 1300`
Verification	Run the **show ipv6 interface** command to check whether the configuration takes effect.
	`ND retransmit interval is 1000 milliseconds` `ND advertised retransmit interval is 0 milliseconds` `ND router advertisements are sent every 200 seconds<160--240>` `ND router advertisements live for 1800 seconds`

3.4.4 Enabling IPv6 Source Routing

Configuration Effect

RFC 5095 abolished the Type 0 routing header. Ruijie devices do not support the Type 0 routing header by default. The administrator can run the **ipv6 source-route** command to in global configuration mode to enable IPv6 source routing.

Configuration Steps

↘ Enabling IPv6 Source Routing

- Optional.
- To enable IPv6 source routing, run the **ipv6 source-route** command.

Verification

The device can properly forward packets carrying the Type 0 routing header.

Related Commands

↘ Enabling IPv6 Source Routing

Command	**ipv6 source-route**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Since the Type 0 header may cause the device prone to DoS attacks, the device does not forward IPv6 packets carrying the routing header by default, but still processes IPv6 packets with itself being the final destination address and the Type 0 routing header.

Configuration Example

↘ Enabling IPv6 Source Routing

Configuration Steps	Enable IPv6 source routing.
	`Ruijie(config)#ipv6 source-route`
Verification	Run the **show run** command to check whether the configuration takes effect.
	`Ruijie#show run | inc ipv6 source-route` `ipv6 source-route`

3.4.5 Configuring the Sending Rate of ICMPv6 Error Messages

Configuration Effect

Configure the sending rate of ICMPv6 error messages.

Configuration Steps

Configuring the Sending Rate of ICMPv6 Packet Too Big Messages

- Optional.
- If a device receives many IPv6 packets with the packet length exceeding the IPv6 MTU of the outbound interface and thereby sends many ICMPv6 Packet Too Big messages to consume much CPU resources, run the **ipv6 icmp error-interval too-big** command to restrict the sending rate of this error message.

Configuring the Sending Rate of Other ICMPv6 Error Messages

- Optional.
- If a device receives many illegal IPv6 packets and thereby generates many ICMPv6 error messages, run the **ipv6 icmp error-interval** command to restrict the sending rate of ICMPv6 error messages. (This command does not affect the sending rate of ICMPv6 Packet Too Big messages.)

Verification

Run the **show running-config** command to check whether the configuration takes effect.

Related Commands

Configuring the Sending Rate of ICMPv6 Packet Too Big Messages

Command	**ipv6 icmp error-interval too-big** *milliseconds* [*bucket-size*]
Parameter Description	*milliseconds*: Indicates the refresh period of a token bucket, ranging from 0 to 2,147,483,647. The unit is millisecond. The default value is 100. If the value is 0, the sending rate of ICMPv6 error messages is not restricted. *bucket-size*: Indicates the number of tokens in a token bucket, ranging from 1 to 200. The default value is 10.
Command	Global configuration mode

Mode	
Usage Guide	To prevent DoS attacks, use the token bucket algorithm to restrict the sending rate of ICMPv6 error messages. If the length of an IPv6 packet to be forwarded exceeds the IPv6 MTU of the outbound interface, the router discards this IPv6 packet and sends back an ICMPv6 Packet Too Big message to the source IPv6 address. This error message is mainly used as part of the IPv6 PMTUD process. If other ICMPv6 error messages are excessive, ICMPv6 Packet Too Big messages cannot be sent, causing failure of IPv6 PMTUD. Therefore, it is recommended to restrict the sending rate of ICMPv6 Packet Too Big messages independently of other ICMPv6 error messages. Since the precision of the timer is 10 milliseconds, it is recommended to set the refresh period of a token bucket to an integer multiple of 10 milliseconds. If the refresh period of the token bucket is between 0 and 10, the actual refresh period is 10 milliseconds. For example, if the sending rate is set to 1 every 5 milliseconds, two error messages are sent every 10 milliseconds in actual situations. If the refresh period of the token bucket is not an integer multiple of 10 milliseconds, it is automatically converted to an integer multiple of 10 milliseconds. For example, if the sending rate is set to 3 every 15 milliseconds, two tokens are refreshed every 10 milliseconds in actual situations.

Configuring the Sending Rate of Other ICMPv6 Error Messages

Command	**ipv6 icmp error-interval** *milliseconds* [*bucket-size*]
Parameter Description	*milliseconds*: Indicates the refresh period of a token bucket, ranging from 0 to 2,147,483,647. The unit is millisecond. The default value is 100. If the value is 0, the sending rate of ICMPv6 error messages is not restricted. *bucket-size*: Indicates the number of tokens in a token bucket, ranging from 1 to 200. The default value is 10.
Command Mode	Global configuration mode
Usage Guide	To prevent DoS attacks, use the token bucket algorithm to restrict the sending rate of ICMPv6 error messages. Since the precision of the timer is 10 milliseconds, it is recommended to set the refresh period of a token bucket to an integer multiple of 10 milliseconds. If the refresh period of the token bucket is between 0 and 10, the actual refresh period is 10 milliseconds. For example, if the sending rate is set to 1 every 5 milliseconds, two error messages are sent every 10 milliseconds in actual situations. If the refresh period of the token bucket is not an integer multiple of 10 milliseconds, it is automatically converted to an integer multiple of 10 milliseconds. For example, if the sending rate is set to 3 every 15 milliseconds, two tokens are refreshed every 10 milliseconds in actual situations.

Configuration Example

Configuring the Sending Rate of ICMPv6 Error Messages

Configuration Steps	Set the sending rate of the ICMPv6 Packet Too Big message to 100 pps and that of other ICMPv6 error messages to 10 pps.

	Ruijie(config)#ipv6 icmp error-interval too-big 1000 100 Ruijie(config)#ipv6 icmp error-interval 1000 10
Verification	Run the **show running-config** command to check whether the configuration takes effect.
	Ruijie#show running-config | include ipv6 icmp error-interval ipv6 icmp error-interval 1000 10 ipv6 icmp error-interval too-big 1000 100

3.4.6 Configuring the IPv6 Hop Limit

Configuration Effect

Configure the number of hops of a unicast packet to prevent the packet from being unlimitedly transmitted.

Configuration Steps

Configuring the IPv6 Hop Limit

- Optional.
- To modify the number of hops of a unicast packet, run the **ipv6 hop-limit value** command.

Verification

- Run the **show running-config** command to check whether the configuration is correct.
- Capture the IPv6 unicast packets sent by a host. The packet capture result shows that the hop-limit field value in the IPv6 header is the same as the configured hop limit.

Related Commands

Configuring the IPv6 Hop Limit

Command	**ipv6 hop-limit value**
Parameter Description	*value*: Indicates the number of hops of a unicast packet sent by the device. The value ranges from 1 to 255.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the IPv6 Hop Limit

Configuration Steps	Change the IPv6 hop limit of a device to 250.
	Ruijie(config)#ipv6 hop-limit 250

Verification	Run the **show running-config** command to check whether the configuration takes effect.
	`Ruijie#show running-config` `ipv6 hop-limit 254`

3.4.7 Configuring the Default Gateway on the Management Interface

Configuration Effect

Configure the default gateway on the management interface. A default route is generated, with the outbound interface being the management interface and the next hop being the configured gateway.

Notes

The configuration is supported only on the management interface.

Configuration Steps

Configuring the Default Gateway on the Management Interface

- Optional.
- To configure a default route and the next hop for the management interface, run the **ipv6 gateway** command.

Verification

- Run the **show running-config** command to check whether the configuration is correct.

Related Commands

Configuring the Default Gateway on the Management Interface

Command	**ipv6 gateway** *ipv6-address*
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	This command is supported only on the management interface.

Configuration Example

Configuring the Default Gateway on the Management Interface

Configuration Steps	Sett the default gateway of the management interface to 2000::1.
	`Ruijie(config)# interface mgmt 0` `Ruijie(config-mgmt)# ipv6 gateway 2000::1`
Verification	Run the **show running-config interface vlan 2** command to check whether the configuration takes effect.

Configuration Steps	Sett the default gateway of the management interface to 2000::1.
	`Ruijie(config)# interface mgmt 0` `Ruijie(config-mgmt)# ipv6 gateway 2000::1`
Verification	Run the **show running-config interface vlan 2** command to check whether the configuration takes effect.
	`Ruijie#show running-config interface mgmt 0` `Ipv6 gateway 2000::1`

3.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the dynamically learned neighbors.	**clrear ipv6 neighbors** [*interface-id*]

Displaying

Description	Command
Displays IPv6 information of an interface.	**show ipv6 interface** [[*interface-id*] [ra-info]] [brief [*interface-id*]]
Displays neighbor information.	**show ipv6 neighbors** [**verbose**] [*interface-id*] [*ipv6-address*] [static]

Debugging

System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Description	Command
Debugs ND entry learning.	**debug ipv6 nd**

4 Configuring DHCP

4.1 Overview

The Dynamic Host Configuration Protocol (DHCP) is a LAN protocol based on the User Datagram Protocol (UDP) for dynamically assigning reusable network resources, for example, IP addresses.

The DHCP works in Client/Server mode. A DHCP client sends a request message to a DHCP server to obtain an IP address and other configurations. When a DHCP client and a DHCP server are not in a same subnet, they need a DHCP relay to forward DHCP request and reply packets.

Protocols and Standards

- RFC2131: Dynamic Host Configuration Protocol
- RFC2132: DHCP Options and BOOTP Vendor Extensions
- RFC3046: DHCP Relay Agent Information Option

4.2 Applications

Application	Description
Providing DHCP Service in a LAN	Assigns IP addresses to clients in a LAN.
Enabling DHCP Client	Enable DHCP Client.
Applying AM Rule on DHCP Server	Apply DHCP Server in Super VLAN environment.
Deploying DHCP Relay in WLAN	In a WLAN, users from different network segments requests IP addresses.
Applying AM Rule on DHCP Relay	In a Super VLAN, users from different network segments requests IP addresses.
Assigning DNS Addresses Obtained from External DHCP Server	In a WLAN, assign preferentially DNS addresses obtained from external DHCP server in WLAN.

4.2.1 Providing DHCP Service in a LAN

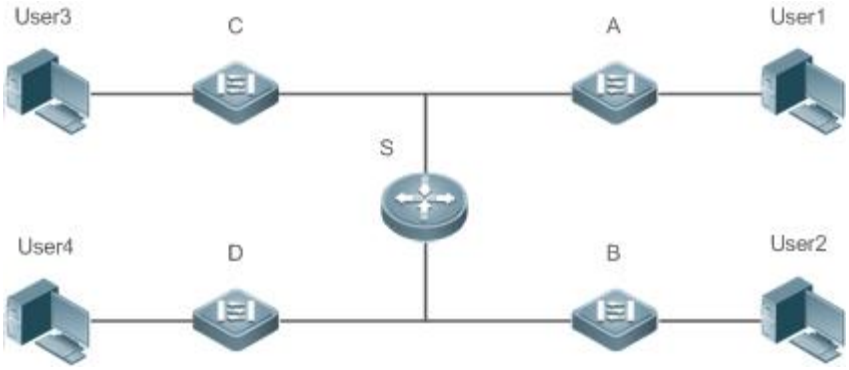
Scenario

Assign IP addresses to four users in a LAN.

For example, assign IP addresses to User 1, User 2, User 3 and User 4, as shown in the following figure.

- The four users are connected to Server S through A, B, C and D.

Figure 4-1



Remarks	S is an egress gateway working as a DHCP server. A, B, C and D are access switches achieving layer-2 transparent transmission. User 1, User 2, User 3 and User 4 are LAN users.

Deployment

- Enable DHCP Server on S.
- Deploy layer-2 VLAN transparent transmission on A, B, C and D.
- User 1, User 2, User 3 and User 4 initiate DHCP client requests.

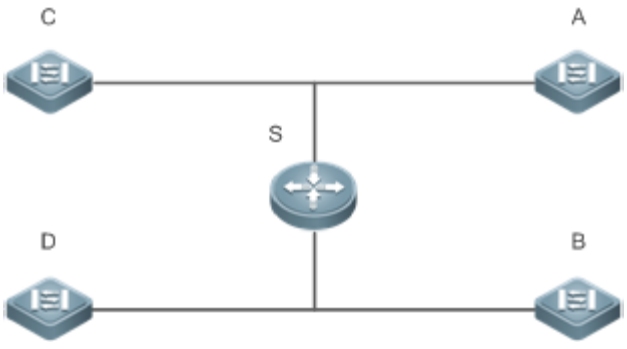
4.2.2 Enabling DHCP Client

Scenario

Access switches A, B, C and D in a LAN request server S to assign IP addresses.

For example, enable DHCP Client on the interfaces of A, B, C and D to request IP addresses, as shown in the following figure.

Figure 4-2



Remarks	S is an egress gateway working as a DHCP server. A, B, C and D are access switches with DHCP Client enabled on the interfaces.

Deployment

- Enable DHCP Server on S.
- Enable DHCP Client on the interfaces of A, B, C and D.

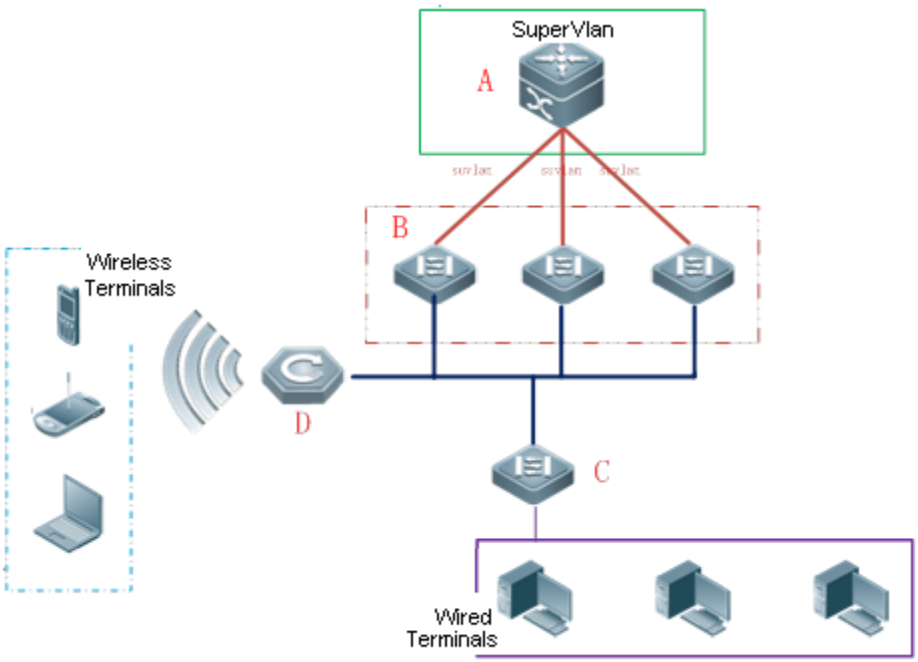
4.2.3 Applying AM Rule on DHCP Server

Scenario

As shown in Figure 4-3, create a Super VLAN, configure an AM rule and enable DHCP Server on the core switch A. B is an aggregation switch, C an access switch, and D a wireless access device. The requirements are listed as follows:

- Assign IP addresses dynamically based on the VLAN and port;
- Assign IP addresses statically based on the VLAN;
- Assign IP addresses dynamically based on the default AM rule.

Figure 4-3 Applying AM Rule on a DHCP Server



Remarks	A is a core device. B is an aggregation device. C is a wired access device. D is a wireless access device.

Deployment

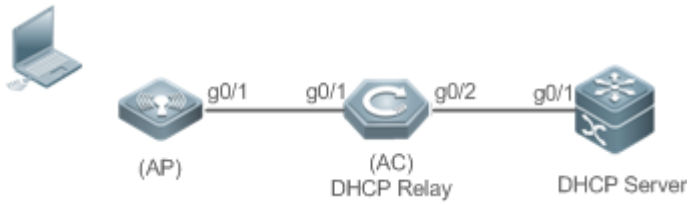
- Configure an AM rule, enable DHCP Server and create a Super VLAN on A.
- Create VLANs on B and C to transparently transmit DHCP packets from wired users to A to request IP addresses.
- Enable the wireless function on D to transparently transmit DHCP packets from wireless users to A to request IP addresses.

4.2.4 Deploying DHCP Relay in WLAN

Scenario

Wireless users in different network segments obtain IP addresses to access the Internet.

Figure 4-4 DHCP Relay



Remarks	AP is a wireless access point. AC is a wireless management device and DHCP Relay agent. DHCP Server is a core device responsible for assigning IP addresses to wireless users.

Deployment

- Connect AP to AC.
- Enable DHCP Relay on AC.
- Enable DHCP Server on the core device.

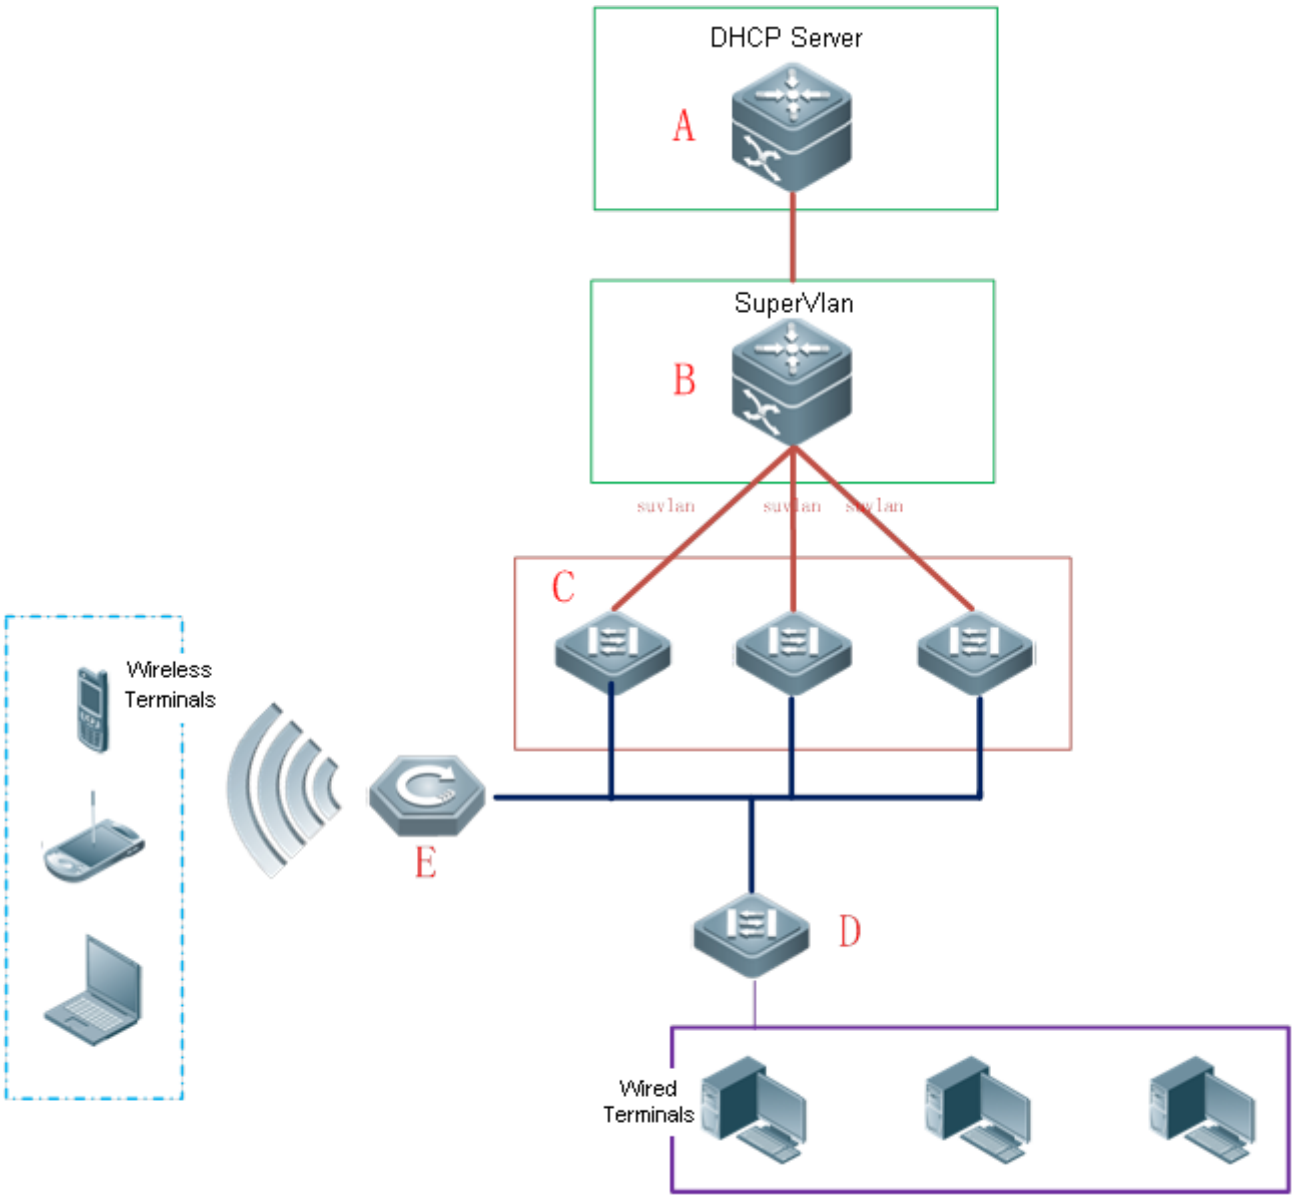
4.2.5 Applying AM Rule on DHCP Relay

Scenario

As shown in Figure 4-5, A is a DHCP server, B a core switch configured with Super VLAN, an AM rule and DHCP Relay, C an aggregation switch, D an access switch, and E a wireless access device. The requirements are listed as follows:

- Based on the VLAN-port AM rule, the DHCP relay agent chooses a subnet address as Giaddress of relay packets and forwards them to the DHCP server to request an IP address for the client.
- Based on default AM rule, the DHCP relay agent chooses a subnet address as Giaddress of relaying packets and forwards them to the DHCP server to request an IP address for the client.

Figure 4-5 Applying AM Rule on DHCP Relay



Remarks	A is a core device. B is a core device. C is an aggregation device. D is a wired access device. E is a wireless access device.

Deployment

- Enable DHCP Server on A.
- Configure an AM rule, enable DHCP Relay and create a Super VLAN on B.
- Create VLANs on C and D to transparently transmit DHCP packets from wired users to B to request IP addresses.

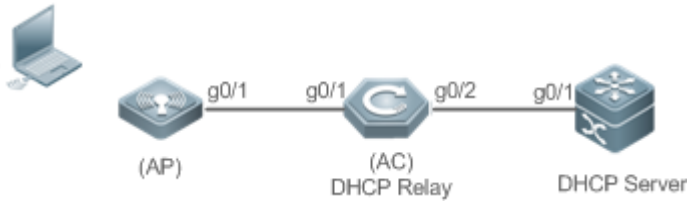
- Enable the wireless function on E to transparently transmit DHCP packets from wireless users to B to request IP addresses.

4.2.6 Assigning Preferentially DNS Addresses Obtained from External DHCP Server in WLAN

Scenario

When the WAN port of a wireless fat AP operates in PPPoE or DHCP Client mode, a DNS address can be automatically obtained from an external DHCP server and be configured on the DHCP server of the local device, so that the user does not need to perform DNS configuration. When the fat AP serves as the DHCP server, it preferentially assigns STAs with DNS addresses obtained from an external DHCP server.

Figure 4-6 DHCP Server Network Topology



Remarks	When an AP operates in fat AP mode, and the WAN port of the fat AP operates in PPPoE or DHCP Client mode, the AP can obtain IP addresses and DNS addresses from an external DHCP server, and serves as the DHCP server to assign addresses to STAs.

Deployment

- Configure the AP as a fat AP and enable the PPPoE or DHCP Client function on the WAN port of the fat AP.
- Enable the DHCP server function on the fat AP to assign addresses to STAs.
- Preferentially assign DNS addresses obtained by the PPPoE or DHCP Client module from an external DHCP server to STAs.

4.3 Features

Basic Concepts

↘ DHCP Server

Based on the RFC 2131, Ruijie DHCP server assigns IP addresses to clients and manages these IP addresses.

↘ DHCP Client

DHCP Client enables a device to automatically obtain an IP address and configurations from a DHCP server.

↘ DHCP Relay

When a DHCP client and a DHCP server are not in a same subnet, they need a DHCP relay to forward DHCP request and reply packets.

Lease

Lease is a period of time specified by a DHCP server for a client to use an assigned IP address. An IP address is active when leased to a client. Before a lease expires, a client needs to renew the lease through a server. When a lease expires or is deleted from a server, the lease becomes inactive.

Excluded Address

An excluded address is a specified IP address not assigned to a client by a DHCP server.

Address Pool

An address pool is a collection of IP addresses that a DHCP server may assign to clients.

Option Type

An option type is a parameter specified by a DHCP server when it provides lease service to a DHCP client. For example, a public option include the IP addresses of a default gateway (router), WINS server and a DNS server. DHCP server allows configuration of other options. Though most options are defined in the RFC 2132, you can add user-defined options.

Overview

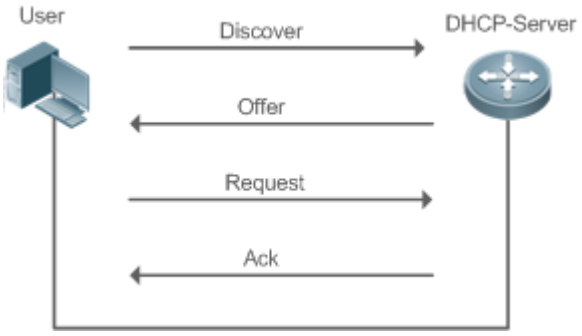
Feature	Description
DHCP Server	Enable DHCP Server on a device, and it may assign IP addresses dynamically and pushes configurations to DHCP clients.
DHCP Relay Agent	Enable DHCP Relay on a device, and it may forward DHCP request and reply packets across different network segments.
DHCP Client	Enable DHCP Client on a device, and it may obtain IP addresses and configurations automatically from a DHCP server.
AM Rule	Enable an AM rule on a device, and it may assign IP addresses according to the rule.

4.3.1 DHCP Server

Working Principle

DHCP Working Principle

Figure 4-7



A host requests an IP address through DHCP as follows:

9. A host broadcasts a DHCP discover packet to find DHCP servers in a network.
10. DHCP servers unicast/broadcast (based on the property of the host packet) DHCP offer packets to the host, containing an IP address, a MAC address, a domain name and a lease.
11. The host broadcasts a DHCP request packet to formally request an IP address.
12. A DHCP server sends a DHCP ACK unitcast packet to the host to acknowledge the request.

A DHCP client may receive DHCPOFFER packets from multiple DHCP servers, but usually it accepts only the first DHCPOFFER packet. Besides, the address specified in a DHCPOFFER packet is not necessarily assigned. Instead, it is retained by the DHCP server until a client sends a formal request.

To formally request an IP address, a client broadcasts a DHCPREQUEST packet so that all DHCP servers sending DHCPOFFER packets may receive the packet and release OFFER IP addresses.

If a DHCPOFFER packet contains invalid configuration parameters, a client will send a DHCPDECLINE packet to the server to decline the configuration.

During the negotiation, if a client does not respond to the DHCPOFFER packets in time, servers will send DHCPNAK packets to the client and the client will reinitiate the process.

During network construction, Ruijie DHCP servers have the following features:

- Low cost. Usually the static IP address configuration costs more than DHCP configuration.
- Simplified configuration. Dynamic IP address assignment dramatically simplifies device configuration
- Centralized management. You can modify the configuration for multiple subnets by simply modifying the DHCP server configuration.

Address Pool

After a server receives a client's request packet, it chooses a valid address pool, determines an available IP address from the pool through PING, and pushes the pool and address configuration to the client. The lease information is saved locally for validity check upon lease renewal.

An address pool may carry various configuration parameters as follows:

- An IP address range, which is the range of IP addresses that are available.
- A gateway address. A maximum of 8 gateway addresses are supported.

- A DNS address. A maximum of 8 DNS addresses are supported.
- A lease period notifying clients of when to age an address and request a lease renewal.

VRRP Monitoring

In a Virtual Router Redundancy Protocol (VRRP) scenario, Ruijie devices enabled with DHCP provide a command to monitor the VRRP status of the interface. To an interface configured with VRRP address and VRRP monitoring, a DHCP server only processes the DHCP clients' request packets from the interface in Master state, and other packets are discarded. If no VRRP address is configured, the DHCP server does not monitor the VRRP status, and all DHCP packets are processed. VRRP monitoring is configured on only layer-3 interfaces. It is disabled by default, namely, only the Master device processes the DHCP service.

IP Address Assignment Based on VLANs, Ports and IP Range

After an IP address pool is deployed, the specified IP address range is assigned based on VLANs and ports. There are three scenarios. 1. Global configuration. 2. Configuration based on VLANs, ports and IP range. 3. Both 1 and 2. In scenario 1, the addresses are assigned globally. In scenario 2, the addresses in the specified IP range are assigned only to the clients of the specified VLANs and ports. In scenario 3, the clients of the specified VLANs and ports are assigned the addresses in the specified IP range, and the other clients are configured with default global addresses.

Adding Trusted ARP

A trusted ARP prevents gateway ARP spoofing. Ruijie devices enabled with DHCP provide a command for pushing a trusted ARP while assigning an address. After this function is enabled, DHCP server pushes it while assigning an IP address to the client to prevent ARP spoofing.

ARP-Based Offline Detection

Ruijie devices enabled with DHCP provide a command to enable ARP-based offline detection. After this function is enabled, a DHCP server will receive an ARP aging notification when a client gets offline, and start retrieving the client's address. If the client does not get online within a period of time (5 minutes by default), the DHCP server will retrieve the address and assign it to another client. If the client gets online again, the address is still valid.

Adding Pseudo Server Detection

If a DHCP server is deployed illegally, a client interacts with this server while requesting an IP address and a wrong address will be assigned to the client. This server is a pseudo server. Ruijie devices enabled with DHCP provides a command to enable pseudo server detection. After it is enabled, DHCP packets are checked for Option 54 (Server Identifier Option). If the content of Option 54 is different from the actual DHCP server identifier, the IP address of the pseudo server and port receiving the packets will be recorded. The pseudo server detection is only an after-event security function and cannot prevent an illegal DHCP server from assigning IP addresses to clients.

Related Configuration

Enabling DHCP Server Globally

- By default, DHCP Server is disabled.

- Run the **service dhcp** command to enable the DHCP Server.
- Run the **service dhcp** command globally to enable DHCP service.

↘ Configuring Address Pool

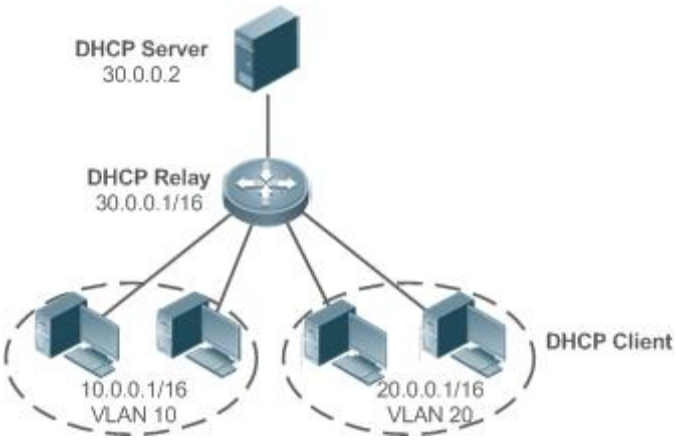
- By default, no address pool is configured.
- Run the **ip dhcp pool** command to configure an IP address range, a gateway and a DNS.
- If no address pool is configured, no addresses will be assigned.

4.3.2 DHCP Relay Agent

Working Principle

The destination IP address of DHCP request packets is 255.255.255.255, and these packets are forwarded within a subnet. To achieve IP address assignment across network segments, a DHCP relay agent is needed. The DHCP relay agent unicasts DHCP request packets to a DHCP server and forwards DHCP reply packets to a DCHP client. The DHCP relay agent serves as a repeater connecting a DHCP client and a DHCP server of different network segments by forwarding DHCP request packets and DHCP reply packets. The Client-Relay-Server mode achieves management of IP addresses across multiple network segments by only one DHCP server. See the following figure.

Figure 4-8 DHCP Relay Scenario



VLAN 10 and VLAN 20 correspond to the segments 10.0.0.1/16 and 20.0.0.1/16 respectively. A DHCP server with IP address 30.0.0.2 is in segment 30.0.0.1/16. To achieve management of dynamic IP addresses in VLAN 10 and VLAN 20 by the DHCP server, you only need to enable DHCP Relay on a gateway and configure IP address 30.0.0.2 for the DHCP server.

↘ DHCP Relay Agent Information (Option 82)

As defined in RFC3046, an option can be added to indicate a DHCP client's network information when DHCP Relay is performed, so that a DHCP server may assign IP addresses of various privileges based on more accurate information. The option is called Option 82. Currently, Ruijie devices support four schemes of relay agent information, which are described respectively as follows:

a) Relay agent information option82: This scheme serves without correlation with other protocol modules. A DHCP relay agent forms an Option 82 based on the physical port receiving DHCP request packets and the MAC address of the device. The option format is shown in the following figure.

Figure 4-9 Agent Circuit ID

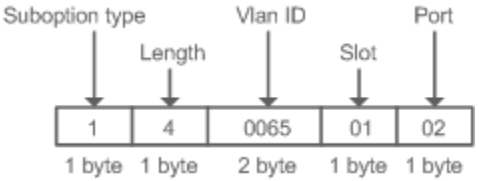


Figure 4-10 Agent Remote ID

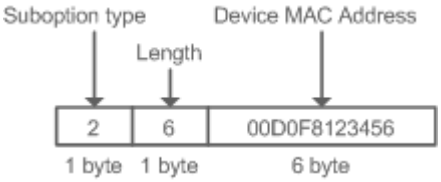

DHCP Relay Check Server-ID

- In DHCP environment, multiple DHCP servers are deployed for a network, achieving server backup to ensure uninterrupted network operation. After this function is enabled, the DHCP request packet sent by a client contains a **server-id** option specifying a DHCP server. In alleviating the burden on servers in specific environments, you need to enable this function on a relay agent to send a packet to a specified DHCP server rather than all DHCP servers.

DHCP Relay suppression

After you configure the **ip DHCP Relay suppression** command on an interface, DHCP request packets received on the interface will be filtered, and the other DHCP request packets will be forwarded.

Related Configuration

Enabling DHCP Relay

- By default, DHCP Relay is disabled.
- You may run the **service dhcp** command to enable DHCP Relay.
- You need to enable DHCP Relay before it works.

Configuring IP Address for DHCP Server

- By default, no IP address is configured for a DHCP server.
- You may run the **ip helper-address** command to configure an IP address for a DHCP server. The IP address can be configured globally or on a layer-3 interface. A maximum of 20 IP addresses can be configured for a DHCP server.

Enabling DHCP Option 82

- By default, DHCP Option 82 is disabled.

- You may run the **ip dhcp relay information option82** command to enable DHCP Option 82.

Enabling DHCP Relay Check Server-ID

- By default, DHCP Relay check server-id is disabled.
- You may run the **ip dhcp relay check server-id** command to enable DHCP Relay check server-id.

Enabling DHCP Relay Suppression

- By default, DHCP Relay suppression is disabled on all interfaces.
- You may run the **ip dhcp relay suppression** command to enable it on an interface.

4.3.3 DHCP Client

Working Principle

A DHCP client broadcasts a DHCP discover packet after entering the Init state. Then it may receive multiple DHCP offer packets. It chooses one of them and responds to the corresponding DHCP server. After that, it sends lease renewal request packets in the Renew and Rebind processes of an aging period to request lease renewal.

Related Configuration

Enabling DHCP Client on Interface

- By default, DHCP Client is disabled.
- In interface configuration mode, you may run the **ip address dhcp** command to enable DHCP Client.
- You need to enable DHCP Client to enable DHCP service.
- The configuration takes effect on a layer-3 interface, for example, an SVI or a routed port.

4.3.4 AM Rule

Working Principle

An AM rule defines the range of IP addresses assigned to DHCP clients in different VLANs and ports. It can be used to quickly identify the VLAN and port of a faulty DHCP client and effectively assign addresses. After an AM rule is configured, all DHCP clients from the set VLAN and ports may obtain IP addresses. If no AM rule is configured, there are two following cases: If a default AM rule is configured, the client obtains an IP address from the default range; if no default AM rule is configured, the client cannot obtain an IP address.

Related Configuration

Configuring AM Rule in Global Configuration Mode

- In global configuration mode, run the **address-manage** command to enter AM rule configuration mode.
- Run the **match ip default** command to configure a default AM rule.
- Run the **match ip** command to configure an AM rule based on VLAN & port or port.

4.4 Configuration

Configuring DHCP Server

Configuration	Description and Command	
Configuring Dynamic IP Address	(Mandatory) It is used to enable DHCP Server to achieve dynamic IP address assignment.	
	service dhcp	Enables DHCP Server.
	ip dhcp pool	Configures an address pool.
	network	Configures the network number and subnet mask of a DHCP address pool.
	(Optional) It is used to configure the properties of an address pool.	
	default-router	Configures a default gateway of a client.
	lease	Configures an address lease.
	next-server	Configures a TFTP server address
	bootfile	Configures a boot file of a client.
	domain-name	Configures a domain name of a client.
	dns-server	Configures a domain name server.
	netbios-name-server	Configures a NetBIOS WINS server.
	netbios-node-type	Configures a NetBIOS node type on a client.
	lease-threshold	Configures an alarm threshold of an address pool.
	option	Configures a user-defined option.
	pool-status	Enables or disables an address pool.
	update arp	Adds a trusted ARP while assigning addresses from a pool.
Configuring Static IP Address	(Optional) It is used to statically assign an IP address to a client.	
	ip dhcp pool	Configures an address pool name and enters address pool configuration mode.
	host	Configures the IP address and subnet mask of a client host.
	hardware-address	Configures a client hardware address.
	client-identifier	Configures a unique client identifier.
	client-name	Configures a client name.
Configuring Global Properties of DHCP Server	(Optional) It is used to configure the properties of a DHCP server.	
	ip dhcp excluded-address	Configures an excluded IP address.
	ip dhcp force-send-nak	Configures Compulsory NAK reply by a DHCP server.

Configuration	Description and Command	
	ip dhcp monitor-vrrp-state	Configures VRRP status monitoring.
	ip dhcp ping packets	Configures ping times.
	ip dhcp ping timeout	Configures a ping timeout.
	ip dhcp refresh arp	Configures a DHCP server to refresh trusted ARPs.
	ip dhcp server arp-detect	Configures a DHCP server to detect user offline.
	ip dhcp server detect	Configures pseudo server detection.
Configuring AM Rule for DHCP Server	(Optional) It is used to configure the AM rule of a DHCP server.	
	address-manage	Enters AM configuration mode.
	match ip default	Configures a default AM rule.
	match ip	Configures AM rule based on VLAN/VLAN and port.

Configuring DHCP Relay

Configuration	Description and Command	
Configuring Basic DHCP Relay Functions	(Mandatory) It is used to enable DHCP Relay.	
	service dhcp	Enables DHCP Relay.
	ip helper-address	Configures an IP Address of a DHCP Server.
Configuring DHCP Relay Option 82	(Optional) It is used to assign IP addresses of different privileges to clients in combination with the information of a physical port. This function cannot be used together with the **dhcp option dot1x** command.	
	ip dhcp relay information option82	Enables DHCP option82.
Configuring DHCP Relay Check Server-ID	(Optional) It is used to enable a DHCP Relay agent to send DHCP request packets only to a specified server.	
	ip dhcp relay check server-id	Enables a DHCP Relay agent to send DHCP request packets only to a specified server
Configuring DHCP Relay Suppression	(Optional) It is used to shield DHCP request packets on an interface.	
	ip dhcp relay suppression	Enables DHCP Relay Suppression.

Configuring DHCP Client

Configuration	Description and Command	
Configuring DHCP Client	(Mandatory) It is used to enable DHCP Client.	
	ip address dhcp	Enables an Ethernet interface, a PPP/HDLC-encapsulated or FR-encapsulated interface to obtain IP addresses through DHCP.

4.4.1 Configuring Dynamic IP Address

Configuration Effect

Provide all DHCP clients with DHCP service including assigning IP addresses and gateways.

Notes

A DHCP server and a DHCP relay share the **service dhcp** command, but a device cannot function as a DHCP server and relay at the same time. When a device is configured with a valid address pool, it acts as a server and forwards packets. Otherwise, it serves as a relay agent.

Configuration Steps

Enabling DHCP Server

- Mandatory. It achieves dynamic IP address assignment.
- Run the **service dhcp** command in global configuration mode.

Configuring Address Pool

- Mandatory. It is used to create an IP address pool.
- Run the **ip dhcp pool** command in global configuration mode.

Configuring Network Number and Subnet Mask of DHCP Address Pool

- Mandatory. It defines a range of dynamically assigned addresses.
- Run the **network** command in DHCP address pool configuration mode.

Configuring Default Gateway of Client

- Optional. It is used to configure a gateway address.
- Run the **default-router** command in DHCP address pool configuration mode.

Configuring Address Lease

- Optional. It is used to configure an IP address lease, which is 24h by default.
- Run the **lease** command in DHCP address pool configuration mode.

Configuring TFTP Server Address

- Optional. It is used to configure a TFTP server address.
- Run the **next-server** command in DHCP address pool configuration mode.

Configuring Domain Name of Client

- Optional. It is used to configure the domain name of a client.
- Run the **domain-name** command in DHCP address pool configuration mode.

Configuring DNS

- Optional. It is used to configure a DNS address.
- Run the **dns** command in DHCP address pool configuration mode.

Configuring NetBIOS WINS Server

- Optional. It is used to configure a NetBIOS WINS server address.
- Run the **netbios-name-server** command in DHCP address pool configuration mode.

Configuring NetBIOS Node Type on Client

- Optional. It is used to configure a NetBIOS node type.
- Run the **netbios-name-type** command in DHCP address pool configuration mode.

Configuring Alarm Threshold of Address Pool

- Optional. It is used to manage the number of leases. When a threshold (90% by default) is reached, an alarm will be printed.
- Run the **lease-threshold** command in DHCP address pool configuration mode.

Configuring User-Defined Option

- Optional. It is used to configure user-defined options.
- Run the **option** command in DHCP address pool configuration mode.

Enabling or Disabling Address Pool

- Optional. It is used to enable or disable an address pool. It is enabled by default.
- Run the **pool-status** command in DHCP address pool configuration mode.

Adding Trusted ARP

- Optional. It is used to add a trusted ARP while assigning an IP address. It is disabled by default.
- Run the **update arp** command in DHCP address pool configuration mode.

Verification

Connect a DHCP client and a DHCP server.

- Check whether the client obtains configurations on the server.

Related Commands

Enabling DHCP Server

Command	**service dhcp**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Enable DHCP Server and DHCP Relay. A DHCP server and a DHCP relay share the **service dhcp** command. When a device is configured with a valid address pool, it acts as a server and forwards packets. Otherwise, it serves as a relay agent.

Configuring Address Pool

Command	**ip dhcp pool** *dhcp-pool*
Parameter Description	*pool-name*: Indicates the name of an address pool.
Command Mode	Global configuration mode
Usage Guide	Before assigning an IP address to a client, you need to configure an address pool name and enter DHCP address pool configuration mode.

Configuring Network Number and Subnet Mask of DHCP Address Pool

Command	**network** *network-number mask* [*low-ip-address high-ip-address*]
Parameter Description	*network-number:* Indicates the network number of an IP address pool. *mask:* Indicates the subnet mask of an IP address pool. If no subnet mask is defined, the natural subnet mask is applied.
Command Mode	DHCP address pool configuration mode
Usage Guide	To configure dynamic address assignment, you need to configure a network number and subnet mask of an address pool to provide a DHCP server with a range of addresses. The IP addresses in a pool are assigned in order. If an address is assigned or exists in the target network segment, the next address will be checked until a valid address is assigned. Ruijie wireless products provide available network segments by specifying start and end addresses. The configuration is optional. If the start and end address are not specified, all IP addresses in the network segment are assignable. For Ruijie products, addresses are assigned based on the client's physical address and ID. Therefore, one client will not be assigned two leases from one address pool. In case of topological redundancy between a client and a server, address assignment may fail.

	To avoid such failures, a network administrator needs to prevent path redundancy in network construction, for example, by adjusting physical links or network paths.

Configuring Default Gateway of Client

Command	**default-router** *address* [*address2…address8*]
Parameter Description	*address*: Indicates the IP address of a default gateway. Configure at least one IP address. *ip-address2…ip-address8:* (Optional) A maximum of 8 gateways can be configured.
Command Mode	DHCP address pool configuration mode
Usage Guide	Configure a default gateway of a client, and a server will push the gateway configuration to the client. The IP addresses of the default gateway and the client should be in a same network.

Configuring Address Lease

Command	**lease** {*days* [*hours]* [*minutes*] | **infinite**}
Parameter Description	*days:* Defines a lease in the unit of day. *hours:* (Optional) Defines a lease in the unit of hour. Please define *days* before *hours*. *minutes:* (Optional) Defines a lease in the unit of minute. Please define *days* and *hours* before *minutes*. **infinite:** Defines an unlimited lease.
Command Mode	DHCP address pool configuration mode
Usage Guide	The default lease of an IP address assigned by a DHCP server is 1 day. When a lease is expiring soon, a client needs to request a lease renewal. Otherwise the IP address cannot be used after the lease is expired.

Configures Boot File on Client

Command	**bootfile** *filename*
Parameter Description	*file-name*: Defines a boot file name.
Command Mode	DHCP address pool configuration mode
Usage Guide	A boot file is a bootable image file used when a client starts up. The file is usually an OS downloaded by a DHCP client.

Configuring Domain Name of Client

Command	**domain-name** *domain*
Parameter Description	*domain-name:* Defines a domain name of a DHCP client.
Command Mode	DHCP address pool configuration mode
Usage Guide	You may define a domain name for a client. When the client accesses network through the host name, the domain name will be added automatically to complete the host name.

Configuring DNS

Command	**dns-server** *ip-address* [*ip-address2…ip-address8*]
Parameter Description	*ip-address:* Defines an IP address of a DNS server. Configure at least one IP address. *ip-address2…ip-address8:* (Optional) A maximum of 8 DNS servers can be configured. **use-dhcp-client** *interface-type interface-number:* A DHCP client learns its DNS server via RGOS software.
Command Mode	DHCP address pool configuration mode
Usage Guide	If a client accesses network resources through the domain name, you need to configure a DNS server to resolve the domain name.

Configuring NetBIOS WINS Server

Command	**netbios-name-server** *address* [*address2…address8*]
Parameter Description	*address:* Defines an IP address of a WINS server. Configure at least one IP address. *ip-address2…ip-address8:* (Optional) A maximum of 8 WINS servers can be configured.
Command Mode	DHCP address pool configuration mode
Usage Guide	WINS is a domain name service through which a Microsoft TCP/IP network resolves a NetNBIOS name to an IP address. A WINS server is a Windows NT server. When a WINS server starts, it receives a registration request from a WINS client. When the client shuts down, it sends a name release message, so that the computers in the WINS database and on the network are consistent.

Configuring NetBIOS Node Type on Client

Command	**netbios-node-type** *type*
Parameter Description	type: Defines a NetBIOS node type with one of the following approaches. 1. A hexadecimal number, ranging from 0 to FF. Only followings values are available. ● b-node ● p-node ● m-node ● 8 for h-node 2. A character string. ● b-node for a broadcast node; ● p-node for a peer-to-peer node; ● m-node for a mixed node; ● h-node for a hybrid mode.
Command Mode	DHCP address pool configuration mode
Usage Guide	There are four types of NetBIOS nodes of a Microsoft DHCP client. 1) A broadcast node. For such a node, NetBIOS name resolution is requested through broadcast.2) A peer-to-peer node. The client sends a resolution request to the WINS server. 3) A mixed node. The client broadcasts a resolution request and sends the resolution request to the WINS server.. 4) A hybrid node. The client sends a resolution request to

	the WINS server. If no reply is received, the client will broadcast the resolution request. By default, a Microsoft operating system is a broadcast or hybrid node. If no WINS server is configured, it is a broadcast node. Otherwise, it is a hybrid node.

Configuring User-Defined Option

Command	**option** *code* { **ascii** *string* | **hex** *string* | **ip** *ip-address* }
Parameter Description	*code:* Defines a DHCP option code. **ascii** *string:* Defines an ASCII character string. **hex** *string:* Defines a hexadecimal character string. **ip** *ip-address:* Defines an IP address.
Command Mode	DHCP address pool configuration mode
Usage Guide	The DHCP allows transmitting configuration information to a host via a TCP/IP network. DHCP packets contain the option field of definable content. A DHCP client should be able to receive a DHCP packet carrying at least 312 bytes option. Besides, the fixed data field in a DHCP packet is also called an option. In a WLAN, a DHCP client on an AP dynamically requests the IP address of an AC. You may configure on a DHCP server the **option** command specifying the AC address.

Enabling or Disabling Address Pool

Command	**pool-status** {**enable | disable**}
Parameter Description	**enable***:* Enables an address pool. **disable***:* Disable an address pool. It is enabled by default.
Command Mode	DHCP address pool configuration mode
Usage Guide	A Ruijie wireless product provides a command for you to enable/disable a DHCP address pool.

Adding Trusted ARP

Command	**update arp**
Parameter Description	N/A
Command Mode	DHCP address pool configuration mode
Usage Guide	After configuration, a trusted ARP is added when an address is assigned from a pool. A trusted ARP prevents ARP spoofing.

Configuration Example

Configuring Address Pool

Configuration	● Define an address pool net172.

Steps	● The network segment is 172.16.1.0/24. ● The default gateway is 172.16.1.254. ● The address lease is 1 day. ● xcluded addresses range from 172.16.1.2 to 172.16.1.100.
	Ruijie(config)# ip dhcp excluded-address 172.16.1.2 172.16.1.100 Ruijie(dhcp-config)# ip dhcp pool net172 Ruijie(dhcp-config)# network 172.16.1.0 255.255.255.0 Ruijie(dhcp-config)# default-router 172.16.1.254 Ruijie(dhcp-config)# lease 1
Verification	● Run the **show run** command to display the configuration.
	Ruijie(config)#show run | begin ip dhcp ip dhcp excluded-address 172.16.1.2 172.16.1.100 ip dhcp pool net172 network 172.16.1.0 255.255.255.0default-router 172.16.1.254 lease 1

4.4.2 Configuring Static IP Address

Configuration Effect

Assign specific IP addresses and push configuration to specific DHCP clients.

Notes

N/A

Configuration Steps

Configuring Address Pool Name and Entering Address Pool Configuration Mode

- Mandatory. It is used to create an IP address pool.
- Run the **ip dhcp pool** command in global configuration mode.

Configuring IP Address and Subnet Mask of Client

- Mandatory. It is used to configure a static IP address and a subnet mask.
- Run the **host** command in DHCP address pool configuration mode.

Configuring Hardware Address of Client

- Optional. It is used to configure a MAC address.

- Run the **hardware** command in DHCP address pool configuration mode.

Configures Unique Client Identifier

- Optional. It is used to configure a static user identifier (UID).
- Run the **client-identifier** command in DHCP address pool configuration mode.

Configuring Client Name

- Optional. It is used to configure a static client name.
- Run the **host-name** command in DHCP address pool configuration mode.

Verification

Check whether the client obtains the IP address when it is online.

Related Commands

Configuring Address Pool

Command	**ip dhcp pool** *dhcp-pool*
Parameter Description	*pool-name*: Indicates the name of an address pool.
Command Mode	Global configuration mode
Usage Guide	Before assigning an IP address to a client, you need to configure an address pool name and enter address pool configuration mode.

Manual IP Address Binding

Command	**host** *ip-address* [*netmask*] **client-identifier** *unique-identifier* **client-name** *name*
Parameter Description	*ip-address:* Defines the IP address of a DHCP client. *netmask:* Defines the subnet mask of a DHCP client. *unique-identifier:* Defines the hardware address (for example, aabb.bbbb.bb88) and identifier (for example, 01aa.bbbb.bbbb.88) of a DHCP client. *name:* (Optional) It defines a client name using ASCII characters. The name excludes a domain name. For example, name a host **mary** rather than **mary.rg.com**.
Command Mode	DHCP address pool configuration mode
Usage Guide	Address binding means mapping between an IP address and a client's MAC address. There are two kind of address binding. 1) Manual binding. Manual binding can be deemed as a special DHCP address pool with only one address. 2) Dynamic binding. A DHCP server dynamically assigns an IP address from a pool to a client when it receives a DHCP request, creating mapping between the IP address and the client's MAC address.

	To configure manual binding, you need to define a host pool and then specify a DHCP client's IP address and hardware address or identifier. A hardware address is a MAC address. A client identifier includes a network medium type and a MAC address. A Microsoft client is usually identified by a client identifier rather than a MAC address. For the codes of medium types, refer to the *Address Resolution Protocol Parameters* section in the RFC 1700. The Ethernet type is **01**.

Configuration Example

Dynamic IP Address Pool

Configuration Steps	● Configure address pool VLAN 1 with IP address 20.1.1.0 and subnet mask 255.255.255.0. ● The default gateway is 20.1.1.1. ● The lease time is 1 day.
	Ruijie(config)# ip dhcp pool vlan1 Ruijie(dhcp-config)# network 20.1.1.0 255.255.255.0 Ruijie(dhcp-config)# default-router 20.1.1.1 Ruijie(dhcp-config)# lease 1 0 0
Verification	● Run the **show run** command to display the configuration.
	Ruijie(config)#show run | begin ip dhcp ip dhcp pool vlan1 network 20.1.1.0 255.255.255.0 default-router 20.1.1.1 lease 1 0 0

Manual Binding

Configuration Steps	● The host address is 172.16.1.101 and the subnet mask is 255.255.255.0. ● The host name is Billy.rg.com. ● The default gateway is 172.16.1.254. ● The MAC address is 00d0.df34.32a3.
	Ruijie(config)# ip dhcp pool Billy Ruijie(dhcp-config)# host 172.16.1.101 255.255.255.0 Ruijie(dhcp-config)# client-name Billy Ruijie(dhcp-config)# hardware-address 00d0.df34.32a3 Ethernet Ruijie(dhcp-config)# default-router 172.16.1.254
Verification	● Run the **show run** command to display the configuration.
	Ruijie(config)#show run | begin ip dhcp

	ip dhcp pool Billy host 172.16.1.101 255.255.255.0 client-name Billy hardware-address 00d0.df34.32a3 Ethernet default-router 172.16.1.254

4.4.3 Configuring AM Rule for DHCP Server

Configuration Effect

Assign IP addresses according to an AM rule based on a port and a VLAN.

Notes

Ruijie products support AM rule configuration on Ethernet, GB, FR, PPP and HDLC interfaces.

Configuration Steps

Configuring Address Management

- Mandatory. Enter address management mode.
- Run the **address-manage** command in address management configuration mode.

Verification

Check whether clients in different VLANs and ports obtain the valid IP addresses.

Related Commands

Configuring Default Range

Command	**match ip default** *ip-address netmask*
Parameter Description	*ip-address:* Defines an IP address. *netmask:* Defines a subnet mask.
Command Mode	Address management mode
Usage Guide	After configuration, all DHCP clients are assigned IP addresses from the default range based on the VLAN and port. If this command is not configured, IP addresses will be assigned through the regular process.

Assigning Dynamic IP Address Based on VLAN and Port

Command	**match ip** *ip-address netmask interface* [**add**/**remove**] **vlan** *vlan-list*
Parameter Description	*ip-address:* Defines an IP address. *netmask:* Defines a subnet mask. *interface:* Defines an interface name. *add/remove:* Adds or deletes a specific VLAN.

	vlan-list: Indicates a VLAN index.
Command Mode	Address management mode
Usage Guide	After configuration, DHCP clients are assigned IP addresses from the default address range based on the VLAN and port.

Assigning Static IP Address Based on VLAN

Command	**match ip** *ip-address netmask* [**add**/**remove**] **vlan** *vlan-list*
Parameter Description	*ip-address:* Defines an IP address. *netmask:* Defines a subnet mask. *add/remove:* Adds or deletes a specific VLAN. *vlan-list:* Indicates a VLAN index.
Command Mode	Address management mode
Usage Guide	In a Super VLAN, a client may be assigned a fixed static address no matter which Super VLAN the client resides in. You do not need to configure an AM rule for this IP address based on all sub-VLANs and ports, but only configure an AM rule based on the VLAN. This rule takes effect for only static address assignment.

Configuration Example

Configuring AM Rule

Configuration Steps	● Configure a default rule. ● Configure a rule based on a specific VLAN, port and address range. ● Configure a rule based on a specific VLAN and address range.
	Ruijie(config)# address-manage Ruijie(config-address-manage)# match ip default 172.50.128.0 255.255.128.0 Ruijie(config-address-manage)# match ip 10.1.5.0 255.255.255.0 Gi5/3 vlan 1005 Ruijie(config-address-manage)# match ip 10.1.6.0 255.255.255.0 vlan 1006
Verification	● 1: Run the **show run** command to display the configuration.
	address-manage match ip default 172.50.128.0 255.255.128.0 match ip 10.1.5.0 255.255.255.0 Gi5/3 vlan 1005 match ip 10.1.6.0 255.255.255.0 vlan 1006

4.4.4 Configuring Global Properties of DHCP Server

Configuration Effect

Enable a server with specific functions, for example, ping and compulsory NAK.

Notes

Configuring the command may cause exceptions on other servers.

Configuration Steps

Configuring Excluded IP Address

- Optional. Configure some addresses or address ranges as unavailable.
- Run the **ip dhcp excluded-address** command in global configuration mode.

Configuring Compulsory NAK Reply

- Optional. A server replies to a wrong address request with a NAK packet.
- Run the **ip dhcp force-send-nak** command in global configuration mode.

Configuring VRRP Status Monitoring

- Optional. After configuration, DHCP packets are processed by the Master server.
- Run the **ip dhcp monitor-vrrp-state** command in global configuration mode.

Configuring Ping Times

- Optional. Check the address reachability with the **ping** command. The default is 2.
- Run the **ip dhcp ping packet** command in global configuration mode.

Configuring Ping Timeout

- Optional. Check the address reachability with the **ping** command. The default is 500 ms.
- Run the **ip dhcp ping timeout** command in global configuration mode.

Refreshing Trusted ARP

- Configure a DHCP server to refresh trusted ARPs according to the addresses assigned from an address pool configured with the **update arp** command.
- Run the **ip dhcp refresh arp** command in global configuration mode.

Detecting User Offline Detection

- Configure a DHCP server to detect whether the client is offline or not. If a client does not get online after being offline for a period, the address assigned to the client will be retrieved.
- Run the **ip dhcp server arp-detect** command in global configuration mode.

Configuring Pseudo Server Detection

- Optional. Enable this function to log a pseudo server.
- Run the **ip dhcp server detect** command in global configuration mode.

Verification

Run the **dhcp-server** command, and check the configuration during address assignment.

Related Commands

Configuring Excluded IP Address

Command	**ip dhcp excluded-address** *low-ip-address* [*high-ip-address*]
Parameter Description	*low-ip-address:* Indicates a start IP address. *high-ip-address:* Indicates an end IP address.
Command Mode	Global configuration mode
Usage Guide	Unless otherwise specified, a DHCP server assigns all the addresses from an IP address pool to DHCP clients. To reserve some addresses(e.g., addresses already assigned to the server or devices), you need to configure these addresses as excluded addresses. To configure a DHCP server, it is recommended to configure excluded addresses to avoid address conflict and shorten detection time during address assignment.

Configuring Compulsory NAK Reply

Command	**ip dhcp force-send-nak**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	In a WLAN, a DHCP client often moves from one network to another. When a DHCP server receives a lease renewal request from a client but finds that the client crosses the network segment or that the lease is expired, it replies with a NAK packet to require the client to obtain an IP address again. This prevents the client from sending request packets continually before obtaining an IP address again after timeout. The server sends a NAK packet only when it finds the client's lease record. When a DHCP client crosses the network, a DHCP server cannot find lease record of the client and will not reply with a NAK packet. The client sends request packets continually before obtaining an IP address again after timeout. Consequently, it takes a long to obtain an IP address. This also occurs when a DHCP server loses a lease after restart and a client requests lease renewal. In this case, you may configure a command to force the DHCP server to reply with a NAK packet even though it cannot find the lease record so that the client may obtain an IP address rapidly. Please note that the command is disabled by default. To enable it, only one DHCP server can be configured in a broadcast domain.

Configuring Ping Times

Command	**ip dhcp ping packets** [*number*]
Parameter Description	*number:* (Optional) Ranges from 0 to 10. 0 indicates the ping function is disabled. The default is two pings.
Command Mode	Global configuration mode
Usage Guide	By default, when a DHCP server assigns an IP address from a pool, it runs the **Ping** command twice (one packet per time). If there is no reply, the server takes the address as idle and assigns it to a client. If there is a reply, the server takes the address as occupied and assigns another address.

Configuring Ping Timeout

Command	**ip dhcp ping timeout** *milliseconds*
Parameter Description	*milli-seconds:* Indicates the time that it takes for a DHCP server to wait for a ping reply. The value ranges from 100 ms to 10,000 ms.
Command Mode	Global configuration mode
Usage Guide	By default, if a DHCP server receives no Ping reply within 500 ms, the IP address is available. You may adjust the ping timeout to change the time for a server to wait for a reply.

Refreshing Trusted ARP

Command	**ip dhcp refresh arp**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, if an address pool is configured with the **update arp** command, a DHCP server will refresh trusted ARPs while assigning an IP address from the address pool. If a client clears the trusted ARPs, the server will not reassign them. After configuration, a DHCP server may refresh trusted ARPs according to addresses assigned from an address pool configured with **update arp**.

Configuring ARP-Based Offline Detection

Command	**ip dhcp server arp-detect**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, DHCP server does not detect whether a client is offline or not based on ARP. After configuration, a DHCP server may perform the detection. If a client does not get online again after a period (5 minutes by default), a DHCP server retrieves the address assigned to the client.

Configuring Pseudo Server Detection

Command	ip dhcp server detect
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, pseudo server detection is disabled on a DHCP server. Run this command to enable pseudo server detection.

Configuration Example

Configuring Ping

Configuration Steps	● Set ping times to 5. ● Set ping timeout to 800ms.
	Ruijie(config)# ip dhcp ping packet 5 Ruijie(config)# ip dhcp ping timeout 800
Verification	● Run the **show run** command to display the configuration.
	Ruijie(config)#show run | begin ip dhcp ip dhcp ping packet 5 ip dhcp ping timeout 800

Configuring Excluded IP Address

Configuration Steps	● Configure the excluded IP address from 192.168.0.0 to 192.168.255.255.
	Ruijie(config)# ip dhcp excluded-address 192.168.0.0 192.168.255.255
Verification	● Run the **show run** command to display the configuration.
	Ruijie(config)#show run | begin ip dhcp ip dhcp excluded-address 192.168.0.0 192.168.255.255

4.4.5 Configuring Basic DHCP Relay Functions

Configuration Effect

- Deploy dynamic IP management in Client–Relay–Server mode to achieve communication between a DHCP client and a DHCP server, which are in different network segments.

Notes

- To enable DHCP Relay, you need to configure IPv4 unicast routing in a network.

Configuration Steps

Enabling DHCP Relay

- Mandatory.
- Unless otherwise specified, you need to enable DHCP Relay on a device.

Configuring IP Address for DHCP Server

- Mandatory.
- You need to configure an IP address for a DHCP server.

Verification

- Check whether a client obtains an IP address through DHCP Relay.

Related Commands

Enabling DHCP Relay

Command	**service dhcp**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring IP Address for DHCP Server

Command	**ip helper-address { cycle-mode |** *A.B.C.D* **}**
Parameter Description	*cycle-mode*: Indicates that DHCP request packets are forwarded to all DHCP servers. *A.B.C.D*: Indicates the IP address of a server.
Command Mode	Global configuration mode
Usage Guide	

Configuration Example

Configuring DHCP Relay in Wired Connection

Scenario **Figure 4-11**	

Configuration Steps	● Enable a client with DHCP to obtain an IP address. ● Enable the DHCP Relay function on a DHCP relay agent. ● Configure DHCP Server.
A	Enable a client with DHCP to obtain an IP address.
B	Enable DHCP Relay. Ruijie(config)# service dhcp Configure a global IP address of a DHCP server. Ruijie(config)# ip helper-address 172.2.2.1 Configure an IP address for the port connected to the client. Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if)# ip address 192.1.1.1 255.255.255.0 Configure an IP address for the port connected to the server. Ruijie(config)# interface gigabitEthernet 0/2 Ruijie(config-if-gigabitEthernet 0/2)# ip address 172.2.2.2 255.255.255.0
C	Enable DHCP Server. Ruijie(config)# service dhcp Configure an address pool. Ruijie(config)# ip dhcp pool relay Ruijie (dhcp-config)#network 192.1.1.0 255.255.255.0 Ruijie (dhcp-config)#default-router 192.1.1.1 Configure an IP address for the port connected to the relay agent. Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-gigabitEthernet 0/2)# ip address 172.2.2.1 255.255.255.0
Verification	Check whether the client obtains an IP address. ● Check whether the client obtains an IP address. ● Check the DHCP Relay configuration.
A	The user device obtains an IP address.
B	After login to the DHCP relay agent, run the **show running-config** command in privileged EXEC mode to display DHCP Relay configuration. Ruijie# show running-config service dhcp ip helper-address 172.2.2.1 !

	interface GigabitEthernet 0/1 ip address 192.1.1.1 255.255.255.0 ! interface GigabitEthernet 0/2 ip address 172.2.2.2 255.255.255.0 !

Common Errors

- IPv4 unicast routing configuration is incorrect.
- DHCP Relay is disabled.
- No routing between DHCP relay agent and DHCP server is configured.
- No IP address is configured for the DHCP server.

4.4.6 Configuring DHCP Relay Option 82

Configuration Effect

- Through a DHCP relay agent, a server may assign IP addresses of different privileges to the clients more accurately based on the option information.

Notes

- You need to enable the DHCP Relay function.

Configuration Steps

↘ Enabling Basic DHCP Relay Functions

- Mandatory.
- Unless otherwise specified, you need to enable DHCP Relay on a device.

↘ Enables DHCP Option82

- By default, DHCP Option 82 is disabled.
- You may run the **ip dhcp relay information option82** command to enable or disable DHCP Option 82.

Verification

- Check whether the client obtains an IP address based on Option 82.

Related Commands

↘ Enabling DHCP Option 82

Command	**ip dhcp relay information option82**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Enabling DHCP Option 82

Configuration Steps	● Enable DHCP Option 82.
	Ruijie(config)# ip dhcp relay information option82
Verification	After login to the DHCP relay agent, run the **show running-config** command in privileged EXEC mode to display DHCP Relay configuration.
	Ruijie#show ru | incl ip dhcp relay ip dhcp relay information option82

Common Errors

- Basic DHCP Relay functions are not configured.

4.4.7 Configuring DHCP Relay Check Server-ID

Configuration Effect

- After you configure the **ip dhcp relay check server-id**, a DHCP Relay agent will forward DHCP request packets only to the server specified by the **option server-id** command. Otherwise, they are forwarded to all DHCP servers.

Notes

- You need to enable basic DHCP Relay functions.

Configuration Steps

Enabling DHCP Relay Check Server-ID

- By default, DHCP Relay check server-id is disabled.
- You may run the **ip dhcp relay check server-id** command to enable DHCP Relay check server-id.

Verification

Check whether a DHCP Relay agent sends DHCP request packets only to the server specified by the **option server-id** command.

Related Commands

Configuring DHCP Relay Check Server-ID

Command	**ip dhcp relay check server-id**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring DHCP Relay Check Server-ID

Configuration Steps	● Enable DHCP Relay.Omitted. ● Enable **DHCP Relay check server-id** on an interface.
	Ruijie# configure terminal Ruijie(config)# ip dhcp relay check server-id
Verification	After login to the DHCP relay agent, run the **show running-config** command in privileged EXEC mode to display DHCP Relay configuration.
	Ruijie# show running-config | include check server-id ip dhcp relay check server-id Ruijie#

Common Errors

- Basic DHCP Relay functions are not configured.

4.4.8 Configuring DHCP Relay Suppression

Configuration Effect

- After you configure the **ip DHCP Relay suppression** command on an interface, DHCP request packets received on the interface will be filtered, and the other DHCP requests will be forwarded.

Notes

- You need to enable basic DHCP Relay functions.

Configuration Steps

Enabling DHCP Relay Suppression

By default, DHCP Relay suppression is disabled on all interfaces.

- You may run the **ip dhcp relay suppression** command to enable DHCP Relay suppression.

Verification

- Check whether the DHCP request packets received on the interface are filtered.

Related Commands

Configuring DHCP Relay Suppression

Command	**ip dhcp relay suppression**
Parameter Description	N/A

Configuring DHCP Relay Suppression

Configuration Steps	● Configure basic DHCP Relay functions. ● Configure DHCP Relay suppression on an interface.
	Ruijie# configure terminal Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# ip dhcp relay suppression Ruijie(config-if-GigabitEthernet 0/1)#end Ruijie#
Verification	After login to the DHCP relay agent, run the **show running-config** command in privileged EXEC mode to display DHCP Relay configuration.
	Ruijie# show running-config | include relay suppression ip dhcp relay suppression Ruijie#

Common Errors

Basic DHCP Relay functions are not configured.

4.4.9 Configuring DHCP Client

Configuration Effect

Enable DHCP Client on a device so that it obtains IP addresses and configurations dynamically.

Notes

Ruijie products support DHCP Client configuration on Ethernet, FR, PPP and HDLC interfaces.

Configuration Steps

Run the **ip address dhcp** command on an interface.

Verification

Check whether the interface obtains an IP address.

Related Commands

↘ Configuring DHCP Client

Command	**ip address dhcp**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	● Ruijie products support dynamic IP address obtainment by an Ethernet interface. ● Ruijie products support dynamic IP address obtainment by a PPP-encapsulated interface. ● Ruijie products support dynamic IP address obtainment by an FR-encapsulated interface. ● Ruijie products support dynamic IP address obtainment by an HDLC-encapsulated interface.

Configuration Example

↘ Configuring DHCP Client

Configuration Steps	● 1: Enable port FastEthernet 0/0 with DHCP to obtain an IP address.
	Ruijie(config)# interface FastEthernet0/0 Ruijie(config-if-FastEthernet 0/0)#ip address dhcp
Verification	● 1: Run the **show run** command to display the configuration.
	Ruijie(config)#show run | begin ip address dhcp ip address dhcp

4.5 Monitoring

Clearing

Running the clear commands may lose vital information and interrupt services.

Description	Command
Clears DHCP address binding.	**clear ip dhcp binding** { *address* | *}
Clears DHCP address conflict.	**clear ip dhcp conflict** { *address* | *}
Clears statistics of a DHCP server.	**clear ip dhcp server statistics**
Clears statistics of a DHCP relay.	**clear ip dhcp relay statistics**
Clears statistics of DHCP server performance.	**clear ip dhcp server rate**
Clears information of a DHCP pseudo server.	**clear ip dhcp server detect**

Displaying

Description	Command
Displays DHCP lease.	**show dhcp lease**
Displays DHCP sockets.	**show ip dhcp socket**
Displays assigned IP addresses.	**show ip dhcp binding**
Displays created address pools.	**show ip dhcp pool**
Displays statistics of DHCP Server.	**show ip dhcp server statistic**
Displays statistics of DHCP Relay.	**show ip dhcp relay statistic**
Displays conflicted addresses.	**show ip dhcp conflict**
Displays the DHCP pseudo server.	**show ip dhcp server detect**

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs DHCP agent.	**debug ip dhcp server agent**
Debugs DHCP hot backup.	**debug ip dhcp server ha**
Debugs DHCP address pools.	**debug ip dhcp server pool**
Debugs DHCP VRRP.	**debug ip dhcp server vrrp**
Debugs all DHCP servers.	**debug ip dhcp server all**
Debugs DHCP packets.	**debug ip dhcp client**
Debugs DHCP Relay events.	**debug ip dhcp relay**

5 Configuring DHCPv6

5.1 Overview

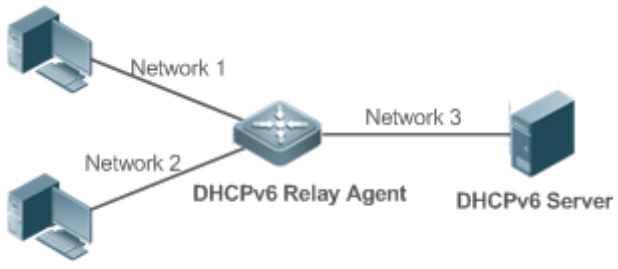
The Dynamic Host Configuration Protocol for IPv6 (DHCPv6) is a protocol that allows a DHCP server to transfer configurations (such as IPv6 addresses) to IPv6 nodes.

As compared with other IPv6 address allocation methods, such as manual configuration and stateless automatic address configuration, DHCPv6 provides the address allocation, prefix delegation, and configuration parameter allocation.

- DHCPv6 is a stateful protocol for automatically configuring addresses and flexibly adding and reusing network addresses, which can record allocated addresses and enhance network manageability.
- By using the prefix delegation of DHCPv6, uplink network devices can allocate address prefixes to downlink network devices, which implements flexible station-level automatic configuration and flexible control of station address space.
- The DHCPv6 configuration parameter allocation solves the problem that parameters cannot be obtained through a stateless automatic address configuration protocol and allocates DNS server addresses and domain names to hosts.
- DHCPv6 is a protocol based on the client/server model. A DHCPv6 client is used to obtain various configurations whereas a DHCPv6 server is used to provide various configurations. If the DHCPv6 client and DHCPv6 server are not on the same network link (the same network segment), they can interact with each other by using a DHCPv6 relay agent.

The DHCPv6 client usually discovers the DHCPv6 server by reserving multicast addresses within a link; therefore, the DHCPv6 client and DHCPv6 server must be able to directly communicate with each other, that is, they must be deployed within the same link. This may cause management inconvenience, economic waste (a DHCPv6 server is deployed for each subnet) and upgrade inconvenience. The DHCPv6 relay agent function can solve these problems by enabling a DHCPv6 client to send packets to a DHCPv6 server on a different link. The DHCP relay agent is often deployed within the link where a DHCPv6 client resides and is used to relay interaction packets between the DHCPv6 client and DHCPv6 server. The DHCP relay agent is transparent to the DHCPv6 client.

Figure 5-1



Protocols and Standards

- RFC3315: Dynamic Host Configuration Protocol for IPv6
- RFC3633: IPv6 Prefix Options for Dynamic Host Configuration Protocol (DHCP) Version 6

- RFC3646: DNS Configuration Options for Dynamic Host Configuration Protocol for IPv6 (DHCPv6)
- RFC3736: Stateless DHCP Service for IPv6
- RFC5417: Control And Provisioning of Wireless Access Points (CAPWAP) Access Controller DHCP Option

5.2 Applications

Application	Description
Requesting/Allocating Addresses and Configuration Parameters	A DHCPv6 client requests addresses from a DHCPv6 server. The DHCPv6 server allocates addresses and configuration parameters to the DHCPv6 client.
Requesting/Allocating Prefixes	The DHCPv6 client requests a prefix from the DHCPv6 server. The DHCPv6 server allocates a prefix to the DHCPv6 client and then the DHCPv6 client configures IPv6 addresses by using this prefix.
Relay Service	The DHCPv6 relay is used to enable communication between the DHCPv6 client and DHCPv6 server on different links.

5.2.1 Requesting/Allocating Addresses and Configuration Parameters

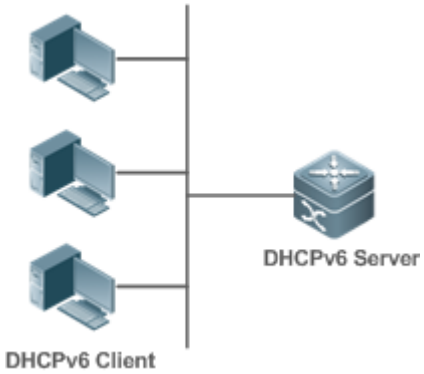
Scenario

In a subnet, a DHCPv6 client requests addresses from a DHCPv6 server. The DHCPv6 server allocates addresses and configuration parameters to the DHCPv6 client.

As shown in Figure 5-2:

- The DHCPv6 server is configured with IPv6 addresses, DNS servers, domain names and other configuration parameters to be allocated.
- A host works as a DHCPv6 client to request an IPv6 address from the DHCPv6 server. After receiving the request, the DHCPv6 server selects an available address and allocates the address to the host.
- The host can also request a DNS server, domain name and other configuration parameters from the DHCPv6 server.

Figure 5-2



Deployment

- Run the DHCPv6 client on a host in the subnet to obtain an IPv6 address and other parameters.
- Run the DHCPv6 server on a device and configure the IPv6 address and other parameters to allocate the IPv6 address and parameters.

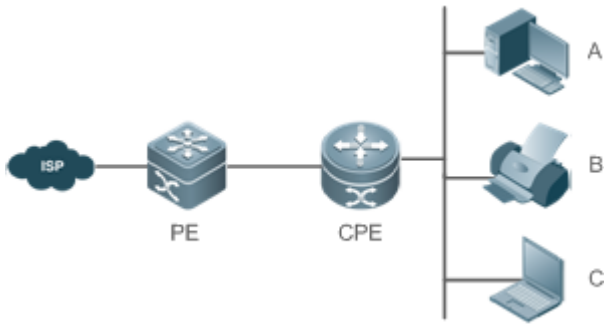
5.2.2 Requesting/Allocating Prefixes

Scenario

As shown in Figure 5-3, an uplink device (PE) allocates an IPv6 address prefix for a downlink device (CPE). The CPE generates a new address prefix for the internal subnet based on the obtained prefix. Hosts in the internal subnet of the CPE are configured with addresses through Router Advertisement (RA) by using the new address prefix.

- The PE provides the prefix delegation service as a DHCPv6 server.
- The CPE requests an address prefix from the PE as a DHCPv6 client. After obtaining the address prefix, the CPE generates a new address prefix for the internal subnet and sends an RA message to hosts in the internal subnet.
- The hosts in the internal subnet where CPE resides configure their addresses based on the RA message sent by the CPE.

Figure 5-3



Remarks	The Provider Edge (PE) works as a DHCPv6 server for providing prefixes and is also called a delegating router. The Customer Premises Equipment (CPE) works as a DHCPv6 client for requesting prefixes and is also called a requesting router. A, B and C are various hosts.

Deployment

- Run the DHCPv6 server on the PE to implement the prefix delegation service.
- Run the DHCPv6 client on the CPE to obtain address prefixes.
- Deploy IPv6 ND between the CPE and the hosts to configure the host addresses in the subnet through RA.

5.2.3 Relay Service

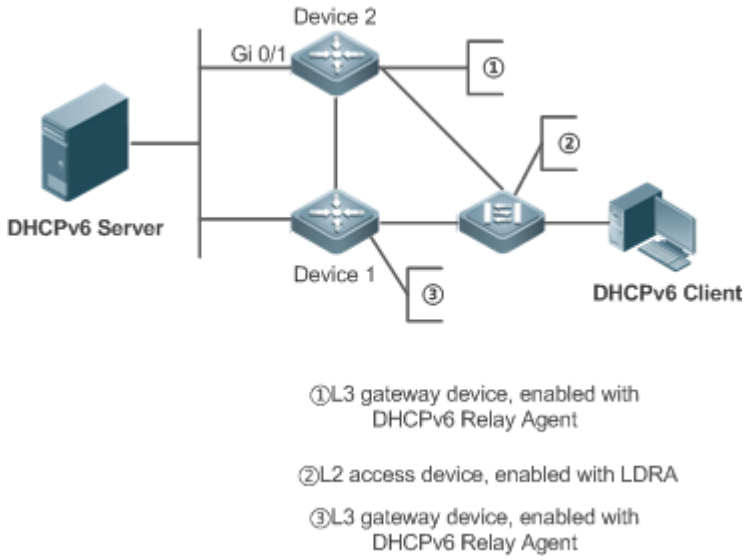
Scenario

The DHCPv6 relay agent provides the relay service for the DHCPv6 client ad DHCPv6 server on different links to enable communication between them.

As shown in Figure 5-4:

- Device 1 is enabled with the DHCPv6 relay agent and destined to 3001::2.
- Device 2 wants to forward packets to other servers through a next-level relay service. Enable the DHCPv6 relay agent on Device 2, set the destination address to FF02::1:2 (all servers and Relay multicast addresses) and specify the egress interface as the layer-3 interface gi 0/1.

Figure 5-4



Deployment

- Enable the DHCPv6 relay agent on device 1 and specify the address as 3000::1.
- Enable the DHCPv6 relay agent on device 2 and specify the address as FF02::1:2.

5.3 Features

Basic Concept

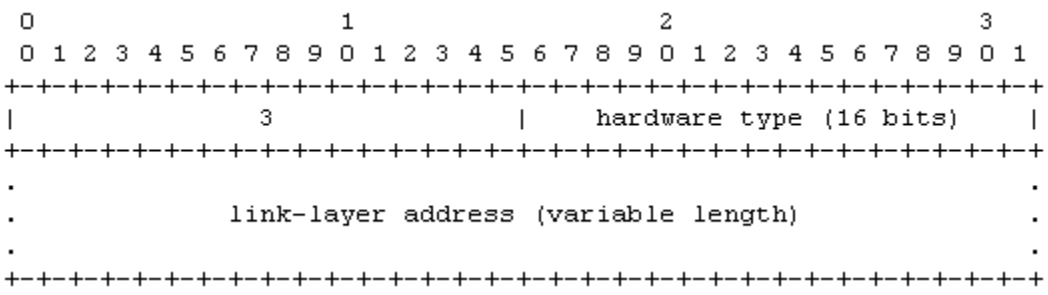
DUID

The DHCP Unique Identifier (DUID) identifies a DHCPv6 device. As defined in RFC3315, each DHCPv6 device (DHCPv6 client, relay or server) must have a DUID, which is used for mutual authentication during DHCPv6 message exchange.

RFC3315 defines three types of DUIDs:

- DUID Based on Link-Layer address plus Time (DUID-LLT).
- DUID Assigned by Vendor Based on Enterprise Number (DUID-EN).
- Link-Layer address (DUID-LL).

Ruijie DHCPv6 devices use DUID-LLs. The structure of a DUID-LL is as follows:



The values of *DUID-LL*, *Hardware type*, and *Link-layer address* are 0x0003, 0x0001 (indicating the Ethernet), and MAC address of a device respectively.

Identity Association (IA)

A DHCPv6 server allocates IAs to DHCPv6 clients. Each IA is uniquely identified by an identity association identifier (IAID). IAIDs are generated by DHCPv6 clients. A one-to-one mapping is established between IAs and clients. An IA may contain several addresses, which can be allocated by the client to other interfaces. An IA may contain one of the following types of addresses:

- Non-temporary Addresses (NAs), namely, globally unique addresses.
- Temporary Addresses (TAs), which are hardly used.
- Prefix Delegation (PD).

Based on the address type, IAs are classified into IA_NA, IA_TA, and IA_PD (three IA-Types). Ruijie DHCPv6 servers support only IA_NA and IA_PD.

Binding

A DHCPv6 binding is a manageable address information structure. The address binding data on a DHCPv6 server records the IA and other configurations of every client. A client can request multiple bindings. The address binding data on a server is present in the form of an address binding table with DUID, IA-Type and IAID as the indexes. A binding containing configurations uses DUID as the index.

DHCPv6 Conflict

When an address allocated by a DHCPv6 client is in conflict, the client sends a Decline packet to notify the DHCPv6 server that the address is rebound. Then, the server adds the address to the address conflict queue. The server will not allocate the addresses in the address conflict queue. The server supports viewing and clearing of address information in the address conflict queue.

Packet Type

RFC3315 stipulates that DHCPv6 uses UDP ports 546 and 547 for packet exchange. Specifically, a DHCPv6 client uses port 546 for receiving packets, while a DHCPv6 server and DHCPv6 relay agent use port 547 for receiving packets. RFC3315 defines the following types of packets that can be exchanged among the DHCPv6 server, client, and relay agent:

- Packets that may be sent by a DHCPv6 client to a DHCPv6 server include Solicit, Request, Confirm, Renew, Rebind, Release, Decline, and Information-request.
- Packets that may be sent by a DHCPv6 server to a DHCPv6 client include Advertise, Reply, and Reconfigure.
- Packets that may be sent by a DHCPv6 relay agent to another DHCPv6 relay agent or a DHCPv6 server include Relay-forward.
- Packets that may be sent by a DHCPv6 relay agent to another DHCPv6 relay agent or a DHCPv6 server include Relay-reply.

Ruijie DHCPv6 servers do not support the Reconfigure packet.

Ruijie DHCPv6 clients do not support the Confirm and Reconfigure packets.

Overview

Feature	Description
Requesting/Allocating Addresses	Dynamically obtains/allocates IPv6 addresses in a network in the client/server mode.
Requesting/Allocating Prefixes	Dynamically obtains/allocates IPv6 prefixes in a network in the client/server mode.
Stateless Service	Provides stateless configuration service for hosts in a network.
Relay Service	Provides the DHCPv6 server service for hosts in different networks by using the relay service.

5.3.1 Requesting/Allocating Addresses

A DHCPv6 client can request IPv6 addresses from a DHCPv6 server.

After being configured with available addresses, a DHCPv6 server can provide IPv6 addresses to hosts in the network, record the allocated addresses and improve the network manageability.

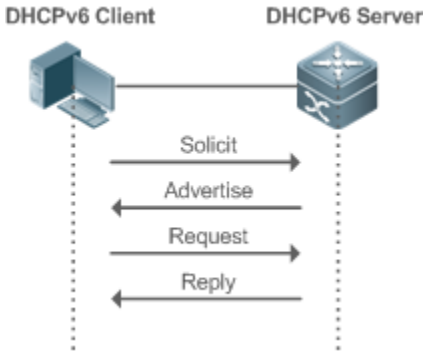
Working Principle

Network hosts serve as DHCPv6 clients and DHCPv6 servers to implement address allocation, update, confirmation, release and other operations through message exchange.

Four-Message Exchange

Figure 5-5 shows the four-message exchange process.

Figure 5-5

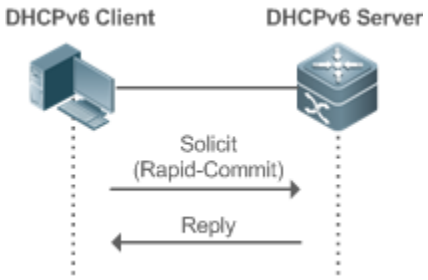


- A DHCPv6 client sends a Solicit message whose destination address is FF02::1:2 and destination port number is 547 within the local link to request address, prefix and configuration parameter allocation. All DHCPv6 servers or DHCPv6 relay agents within the link will receive the Solicit message.
- After receiving the Solicit message, a DHCPv6 server will send an Advertise message in the unicast mode if it can provide the information requested in the Solicit message. The Advertise message includes the address, prefix and configuration parameters.
- The DHCPv6 client may receive the Advertise message from multiple DHCPv6 servers. After selecting the most suitable DHCPv6 server, the DHCPv6 client sends a Request message whose destination address is FF02::1:2 and destination port number is 547 to request address, prefix and configuration parameter allocation.
- After receiving the Request message, the DHCPv6 server creates a binding locally and sends a Reply message in the unicast mode. The Reply message includes the address, prefix and configuration parameters that the DHCPv6 server will allocate to the DHCPv6 client. The DHCPv6 client obtains address, prefix or configuration parameters based on the information in the Reply message.

Two-Message Exchange

Two-message exchange can be used to complete address, prefix and parameter configuration for DHCPv6 clients more quickly.

Figure 5-6



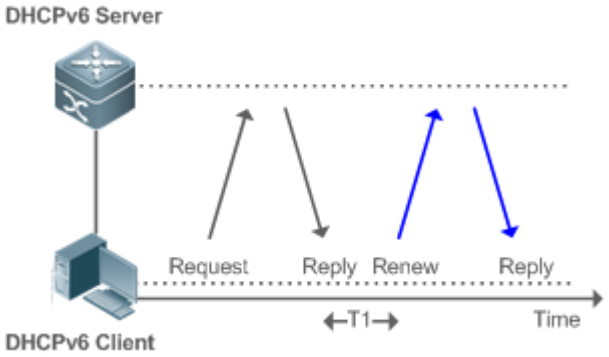
- A DHCPv6 client sends a Solicit message whose destination address is FF02::1:2 and destination port number is 547 within the local link to request address, prefix and configuration parameter allocation. The Solicit message contains Rapid Commit.
- If a DHCPv6 server supports the Rapid Commit option, the DHCPv6 server creates a binding locally and sends a Reply message in the unicast mode. The Reply message includes the address, prefix and configuration parameters to be

allocated to the DHCPv6 client. The DHCPv6 client completes configuration based on the information in the Reply message.

Update and Rebinding

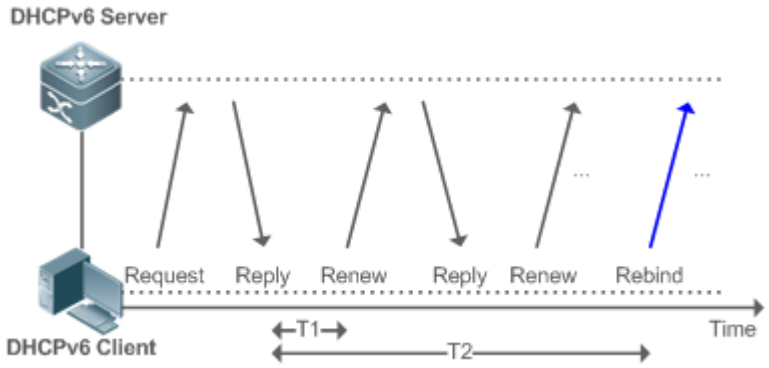
The DHCPv6 server provides the control address and the updated T1 and T2 in the IA of the message sent to the DHCPv6 client.

Figure 5-7



- The DHCPv6 client will send a Renew multicast message to the DHCPv6 server for updating the address and prefix after T1 seconds. The Renew message contains the DUID of the DHCPv6 server and the IA information to be updated.
- After receiving the Renew message, the DHCPv6 server checks whether the DUID value in the Renew message is equal to the DUID value of the local device. If yes, the DHCPv6 server updates the local binding and sends a Reply message in the unicast mode. The Reply message contains the new T1 and other parameter s.

Figure 5-8

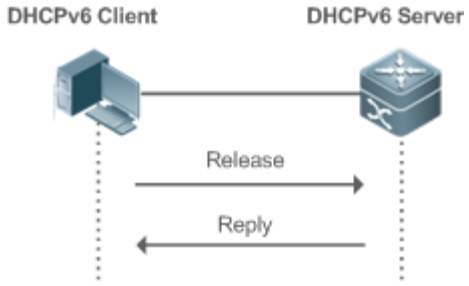


- If no response is received after the DHCPv6 client sends a Renew message to the DHCPv6 server, the DHCPv6 client will send a Rebind multicast message to the DHCPv6 server for rebinding the address and prefix after T2 expires.
- After receiving the Rebind message, the DHCPv6 server (perhaps a new DHCPv6 server) sends a Reply message according to the content of the Rebind message.

Release

If a DHCPv6 client needs to release an address or a prefix, the DHCPv6 client needs to send a Release message to a DHCPv6 server to notify the DHCPv6 server of the released addresses or prefixes. In this way, the DHCPv6 server can allocate these addresses and prefixes to other DHCPv6 clients.

Figure 5-9



- After receiving the Release message, the DHCPv6 server removes the corresponding bindings based on the addresses or prefixes in the Release message, and sends a Reply message carrying the state option to the DHCPv6 client.

Confirmation

After moving to a new link (for example, after restart), a DHCPv6 client will send a Confirm message to the DHCPv6 server on the new link to check whether the original addresses are still available.

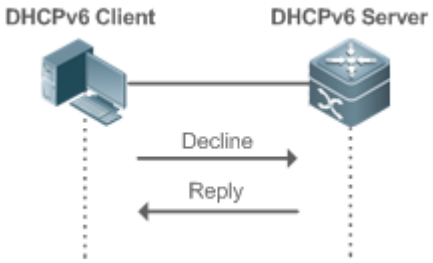
Figure 5-10

- After receiving the Confirm message, the DHCPv6 server performs confirmation based on the address information in the Confirm message, and sends a Reply message carrying the state option to the DHCPv6 client. If the confirmation fails, the DHCPv6 client may initiate a new address allocation request.

DHCPv6 Conflict

If the DHCPv6 client finds that the allocated addresses have been used on the link after address allocation is completed, the DHCPv6 client sends a Decline message to notify the DHCPv6 server of the address conflict.

Figure 5-11



- The DHCPv6 client includes the IA information of the conflicted addresses in the Decline message.
- After receiving the Decline message, the DHCPv6 server marks the addresses in the Decline message as "declined" and will not allocate these addresses . Then, the DHCPv6 server sends a Reply message carrying the state option to the DHCPv6 client. You can manually clear addresses marked as "declined" to facilitate re-allocation.

Related Configuration

Enabling the DHCPv6 Server Function on an Interface

- By default, an interface is not enabled with the DHCPv6 server function.
- You can run the **ipv6 dhcp server** command to enable the DHCPv6 server function for the interface.

The DHCPv6 server function must be enabled on a layer-3 interface.

Allocating Addresses Through the DHCPv6 Server

- By default, the DHCPv6 server has no configuration pool and is not configured with addresses to be allocated.
- You can run the **ipv6 dhcp pool** command to create a configuration pool.
- You can run the **iana-address** command to configure addresses to be allocated and the **preferred lifetime** and **valid lifetime** values.

Clearing Conflicted Addresses Through the DHCPv6 Server

- By default, the DHCPv6 server does not clear conflicted addresses that are detected.
- You can run the **clear ipv6 dhcp conflict** command to clear conflicted addresses so that these addresses can be reused.

Enabling the DHCPv6 Client Address Request Function on an Interface

- By default, an interface is not enabled with the DHCPv6 client address request function.
- You can run the **ipv6 dhcp client ia** command to enable the DHCPv6 client address request function for the interface.

The DHCPv6 client address request function is effective only on a layer-3 interface.

5.3.2 Requesting/Allocating Prefixes

Configure available prefixes on the DHCPv6 server. By using the prefix delegation of DHCPv6, uplink network devices can allocate address prefixes to downlink network devices, which implements flexible station-level automatic configuration and flexible control of station address space.

Working Principle

Downlink network devices serve as DHCPv6 clients to exchange messages with the DHCPv6 server to implement address allocation, update, release and other operations. Downlink network devices obtain, update, rebind and release prefixes by using the four-/two-message exchange mechanism similar to that for allocating addresses. However, prefix allocation is different from address allocation in the following aspects:

- In message exchange using the prefix delegation, the Confirm and Decline messages are not used.
- If a DHCPv6 client moves to a new link and needs to check whether the prefix information is available, it performs confirmation through Rebind and Reply message exchange.
- The IA type in various messages is IA_PD.

For the message exchange using the prefix delegation, refer to the section "Requesting/Allocating Addresses".

Related Configuration

Enabling the DHCPv6 Server Function on an Interface

- By default, an interface is not enabled with the DHCPv6 server function.
- You can run the **ipv6 dhcp server** command to enable the DHCPv6 server function for the interface.

The DHCPv6 server function is effective only on a layer-3 interface.

Prefix Delegation of the DHCPv6 Server

- By default, the DHCPv6 server has no configuration pool and is not configured with prefixes.
- You can run the **ipv6 dhcp pool** command to create a configuration pool.
- You can run the **prefix-delegation** command to allocate specified prefixes to a specific DHCPv6 client.
- You can run the **prefix-delegation pool** command to configure a prefix pool so that all prefixes requested by the DHCPv6 client are allocated from this pool.

Enabling the DHCPv6 Client Prefix Request Function on an Interface

By default, an interface is not enabled with the DHCPv6 client prefix request function.

You can run the **ipv6 dhcp client pd** command to enable or disable the DHCPv6 client prefix request function for the interface.

The DHCPv6 client prefix request function is effective only on a layer-3 interface.

5.3.3 Stateless Service

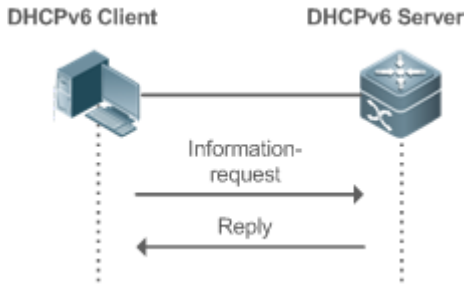
When a DHCPv6 client needs only configuration parameters, the DHCPv6 stateless service can be used to obtain related configuration parameters which cannot be obtained through a stateless automatic address configuration protocol, such as the DNS server address.

Working Principle

Network hosts serve as DHCPv6 clients to exchange messages with the DHCPv6 server to obtain and update configuration parameters.

Message Exchange Using the Stateless Service

Figure 5-12



- A DHCPv6 client sends an Information-request message to a DHCPv6 server to request stateless messages. Usually, this message does not contain the DUID of the specified DHCPv6 server.
- The DHCPv6 server sends a Reply message containing the configuration parameters to the DHCPv6 client.

Related Configuration

Enabling the DHCPv6 Server Function on an Interface

- By default, an interface is not enabled with the DHCPv6 server function.
- You can run the **ipv6 dhcp server** command to enable or disable the DHCPv6 server function for the interface.

⚠ The DHCPv6 server function is effective only on a layer-3 interface.

Stateless Service of a DHCPv6 Server

- By default, the DHCPv6 server has no configuration pool and is not configured with configuration parameters.
- You can run the **ipv6 dhcp pool** command to create a configuration pool.
- You can run the **dns-server** command to add a DNS server.
- You can run the **domain-name** command to add a domain name.
- You can run the **option52** command to add the IPv6 address of the CAPWAP AC.

Stateless Service of a DHCPv6 Client

- By default, an interface is not enabled with the stateless service of the DHCPv6 client.

- If a host receives an RA message containing the O flag, it will enable the stateless service.

5.3.4 Relay Service

When the DHCPv6 client and DHCPv6 server are on different links, the DHCPv6 client can relay related messages to the DHCPv6 server through the DHCPv6 relay agent. The DHCPv6 server also relays the response to the DHCPv6 client through the relay agent.

Working Principle

When receiving a message from the DHCPv6 client, the DHCPv6 relay agent creates a Relay-forward message. This message contains the original message from the DHCPv6 client and some options added by the relay agent. Then, the relay agent sends the Relay-forward message to a specified DHCPv6 server or a specified multicast address FF05::1:3.

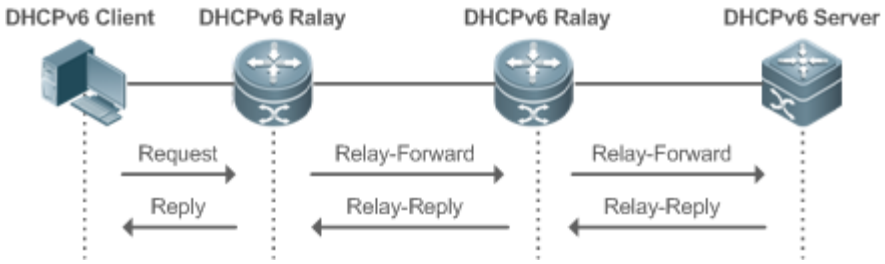
After receiving the Relay-forward message, the DHCPv6 server extracts the original message from the DHCPv6 client f for processing. Then, the DHCPv6 server constructs a response to the original message, encapsulates the response in a Relay-reply message, and then sends the Relay-reply message to the DHCPv6 relay agent.

After receiving the Relay-reply message, the DHCPv6 relay agent extracts the original message from the DHCPv6 server for processing, and forwards the message to the DHCPv6 client.

Multi-level relay agents are allowed between the DHCPv6 client and DHCPv6 server.

DHCPv6 Relay Agent

Figure 5-13



- The DHCPv6 relay agent performs message encapsulation and decapsulation between the DHCPv6 client and DHCPv6 server to enable communication between the DHCPv6 client and DHCPv6 server on different links.

5.3.5 Address Notifying

The DHCPv6 server obtains IPv6 addresses and MAC address of the terminals and notifies them to the authentication module for auditing.

Working Principle

In a subnet without a DHCPv6 Relay device, if IANA address allocating and address notifying are enabled on the DHCPv6 server, the server gets the source MAC addresses from packets and recognizes them as the MAC addresses of terminals. After allocating or renewing IPv6 addresses to the terminals, the IPv6 server notifies to the authentication module the

terminals' MAC and IPv6 addresses, which the module syncs to the authentication server together with IPv4 information. And based on all the received information, the authentication server authenticates or records the treminals.

Related Configuration

Adderess Notifying

- By default, address notifying is disabled.
- Run the **ipv6 dhcp notify** command to enabled address notifying.

5.4 Configuration

Configuration	Description and Command	
Configuring the DHCPv6 Server	(Mandatory) It is used to create a configuration pool.	
	ipv6 dhcp pool	Configures a configuration pool for a DHCPv6 server.
	(Optional) It is used to allocate addresses.	
	iana-address prefix	Configures the address prefixes to be allocated on the DHCPv6 server.
	(Optional) It is used to allocate prefixes.	
	prefix-delegation	Configures prefixes of statically bound addresses on the DHCPv6 server.
	prefix-delegation pool	Configures the DHCPv6 server to allocate prefixes from a local prefix pool.
	ipv6 local pool	Configures a local IPv6 prefix pool.
	(Optional) It is used to allocate configuration parameters.	
	dns-server	Configures the DNS server on the DHCPv6 server.
	domain-name	Configures the domain name of the DHCPv6 server.
	option52	Configures the IPv6 address of the CAPWAP AC on the DHCPv6 server.
	(Mandatory) It is used to enable the DHCPv6 server service.	
	ipv6 dhcp server	Enables the DHCPv6 server service on an interface.
Configuring the DHCPv6 Relay	(Mandatory) It is used to enable the DHCPv6 relay agent service.	
	ipv6 dhcp relay destination	Configures the DHCPv6 relay agent function.

Configuration	Description and Command	
Configuring the DHCPv6 Client	⚠ (Mandatory) It is used to request addresses or prefixes.	
	ipv6 dhcp client ia	Enables the DHCPv6 client and requests IANA addresses.
	ipv6 dhcp client pd	Enables the DHCPv6 client and requests address prefixes.
	⚠ (Optional) It is used to enable a host that receives an RA message to request stateless service through the DHCPv6 client.	
	ipv6 nd other-config-flag	Sets the O flag in the RA message on the device that sends the RA message so that the host that receives the RA message can request stateless service through the DHCPv6 client.

5.4.1 Configuring the DHCPv6 Server

Configuration Effect

- An uplink device can automatically allocate DHCPv6 addresses, prefixes and configuration parameters to a downlink device.

Notes

- To provide the DHCPv6 server service, you must specify a DHCPv6 server configuration pool.
- The name of the configuration pool cannot be too long.
- When enabling the DHCPv6 server service, you must specify a configuration pool.
- Only the Switch Virtual Interface (SVI), routed port and L3 aggregate port (AP) support this configuration.

Configuration Steps

↘ Configuring a DHCPv6 Server Configuration Pool

- Mandatory.
- Unless otherwise specified, you should configure a DHCPv6 server configuration pool on all devices that need to provide the DHCPv6 server service.

↘ Configuring the Address Prefixes to Be Allocated on the DHCPv6 Server

- Optional.
- To provide the address allocation service, you should configure address prefixes to be allocated on all devices that need to provide the DHCPv6 server service.

↘ Configuring Prefixes of Static Addresses on the DHCPv6 Server

- Optional.
- To provide the prefix delegation service for statically bound addresses, you should configure prefixes of statically bound addresses on all devices that need to provide the DHCPv6 server service.

Configuring the DHCPv6 Server to Allocate Prefixes from a Local Prefix Pool

- Optional.
- To provide the prefix delegation service, you should specify a local prefix pool on all devices that need to provide the DHCPv6 server service.

Configuring a Local IPv6 Prefix Pool

- Optional.
- To provide the prefix delegation service through a prefix pool, you should specify a local prefix pool on all devices that need to provide the DHCPv6 server service.

Configuring the DNS Server on the DHCPv6 Server

- Optional.
- To allocate DNS servers, you should configure the DNS server on all devices that need to provide the DHCPv6 server service.

Configuring Domain Names on the DHCPv6 Server

- Optional.
- To allocate domain names, you should configure domain names on all devices that need to provide the DHCPv6 server service.

Configuring the IPv6 Address of the CAPWAP AC on the DHCPv6 Server

- Optional.
- To allocate CAPWAP AC information, you should configure the IPv6 address of the CAPWAP AC on all devices that need to provide the DHCPv6 server service.

Enabling the DHCPv6 Server Service

- Mandatory.
- Unless otherwise specified, you should enable the DHCPv6 server service on specific interfaces of all devices that need to provide the DHCPv6 server service.

Verification

The DHCPv6 server allocates addresses, prefixes or configuration parameters for the DHCPv6 client.

- The DHCPv6 client obtains the required information.
- The DHCPv6 server successfully creates a local binding.

Related Commands

Configuring a DHCPv6 Server Configuration Pool

Command	**ipv6 dhcp pool** *poolname*
Parameter Description	***poolname***: Indicates the name of a user-defined DHCPv6 configuration pool.
Command Mode	Global configuration mode
Usage Guide	Run the **ipv6 dhcp pool** command to create a DHCPv6 server configuration pool. After configuring this command, you may enter the DHCPv6 pool configuration mode, in which you can configure the pool parameters such as the prefix and DNS server. After creating a DHCPv6 server configuration pool, you can run the **ipv6 dhcp server** command to associate the configuration pool with the DHCPv6 server service on an interface.

Configuring the IA_NA Address Prefix for the DHCPv6 Server

Command	**iana-address prefix** *ipv6-prefix/prefix-length* [**lifetime** { *valid-lifetime* | *preferred-lifetime* }]
Parameter Description	*ipv6-prefix/prefix-length*: Indicates an IPv6 address prefix and the prefix length. **lifetime**: Sets the valid time of the address allocated to a client. This keyword must be configured together with *valid-lifetime* and *preferred-lifetime*. *valid-lifetime***:** Indicates the valid time of the address allocated to a client. *preferred-lifetime*: Indicates the time when an address is preferentially allocated to a client.
Command Mode	Interface configuration mode
Usage Guide	Run the **iana-address prefix** command to configure IA_NA address prefixes for a DHCPv6 server, some of which are allocated to the client. When receiving an IA_NA address request from a client, the DHCPv6 server selects an available address according to the IA_NA address range and allocates the address to the client. When the client does not use this address, the DHCPv6 server marks this address as available for another client.

Configuring Prefixes of Statically Bound Addresses on the DHCPv6 Server

Command	**prefix-delegation** *ipv6-prefix/prefix-length client-DUID* [*lifetime*]
Parameter Description	*ipv6-prefix/prefix-length*: Indicates an IPv6 address prefix and the prefix length. *client-DUID*: Indicates the DUID of a client. *lifetime*: Sets the time when the client can use this prefix.
Command Mode	DHCPv6 pool configuration mode
Usage Guide	You can run the **prefix-delegation** command to manually configure a prefix list for an IA_PD of a client and specify the valid time of these prefixes. Use the *client-DUID* parameter to specify the client to which the address prefix is allocated. The address prefix will be allocated to the first IA_PD of the client. After receiving a request for the address prefix from the client, the DHCPv6 server checks whether a static

	binding is available. If yes, the DHCPv6 server directly returns the static binding. If not, the DHCPv6 server allocates the address prefix from another prefix source.

Configuring the DCHPv6 Server to Allocate Prefixes from a local prefix pool

Command	**prefix-delegation pool** *poolname* [**lifetime** { *valid-lifetime* | *preferred-lifetime* }]
Parameter Description	***poolname*:** Indicates the name of a user-defined local prefix pool. **lifetime:** Sets the valid time of the prefix allocated to a client. This keyword must be configured together with *valid-lifetime* and *preferred-lifetime*. *valid-lifetime*: Indicates the valid time of the prefix allocated to the client. *preferred-lifetime*: Indicates the time when a prefix is preferentially allocated to a client.
Command Mode	DHCPv6 pool configuration mode
Usage Guide	Run the **prefix-delegation pool** command to configure a prefix pool for a DHCPv6 server to allocate prefixes to clients. The **ipv6 local pool** command is used to configure a prefix pool. When receiving a prefix request from a client, the DHCPv6 server selects an available prefix from the prefix pool and allocates the prefix to the client. When the client does not use this prefix, the DHCPv6 server retrieves the prefix .

Configuring a Local IPv6 Prefix Pool

Command	**ipv6 local pool** *poolname prefix/prefix-length assigned-length*
Parameter Description	*poolname*: Indicates the name of a local prefix pool. *prefix/prefix-length***:** Indicates the prefix and prefix length. *assigned-length***:** Indicates the length of the prefix allocated to a user.
Command Mode	Global configuration mode
Usage Guide	Run the **ipv6 local pool** command to create a local prefix pool. If the DHCPv6 server needs prefix delegation, you can run the **prefix-delegation pool** command to specify a local prefix pool. Afterwards, prefixes will be allocated from the specified local prefix pool.

Configuring the DNS Server on the DHCPv6 Server

Command	**dns-server** *ipv6-address*
Parameter Description	*ipv6-address*: Indicates the IPv6 address of the DNS server.
Command Mode	DHCPv6 pool configuration mode
Usage Guide	You can run the **dns-server** command for multiple times to configure multiple DNS server addresses. A new DNS server address will not overwrite old DNS server addresses.

Configuring Domain Names on the DHCPv6 Server

Command	**domain-name** *domain*
Parameter	*domain*: Defines a domain name to be allocated to a user.

Description	
Command Mode	DHCPv6 pool configuration mode
Usage Guide	You can run the **domain-name** command for multiple times to create multiple domain names. A new domain name will not overwrite old domain names.

Configuring the option52 on the DHCPv6 Server

Command	**option52** *ipv6-address*
Parameter Description	*ipv6-address*: Specifies the IPv6 address of the CAPWAP AC.
Command Mode	DHCPv6 pool configuration mode
Usage Guide	You can run the **option52** command to configure IPv6 addresses for the multiple CAPWAP ACs. A new CAPWAP AC IPv6 address will not overwrite old IPv6 addresses.

Enabling the DHCPv6 Server Service

Command	**ipv6 dhcp server** *poolname* **[rapid-commit] [preference** *value***]**
Parameter Description	*poolname*: Indicates the name of a user-defined DHCPv6 configuration pool. **rapid-commit:** Permits the two-message exchange process. **preference** *value***:** Configures the priority of the advertise message, ranging from 0 to 255. The default value is 0.
Command Mode	Interface configuration mode
Usage Guide	Run the **ipv6 dhcp server** command to enable the DHCPv6 service on an interface. When the **rapid-commit** keyword is configured, the two-message exchange with a client is permitted during allocation of address prefixes and other configurations. After this keyword is configured, if the Solicit message from a client contains the **rapid-commit** option, the DHCPv6 server will send a Reply message directly. If **preference** is set to a non-0 value, the advertise message sent by the DHCPv6 server contains the **preference** option. The **preference** field affects the server selection by a client. If an advertise message does not contain this field, the value of **preference** is considered **0**. If the value of **preference** received by the client is 255, the client sends a request to the server immediately to obtain configurations. The DHCPv6 client, server, and relay functions are mutually exclusive. An interface can be configured with only one function at a time.

Configuration Example

Configuring the DHCPv6 Server

Configuration Steps	● Configure a configuration pool named "pool1". ● Configure the IA_NA address prefix for the DHCPv6 server. ● Configure prefixes of statically bound addresses on the DHCPv6 server.

	• Configure two DNS servers. • Configure the domain name. • Enable the DHCPv6 server service on an interface.
	Ruijie# configure terminal Ruijie(config)# ipv6 dhcp pool pool1 Ruijie(config-dhcp)# iana-address prefix 2008:50::/64 lifetime 2000 1000 Ruijie(config-dhcp)# prefix-delegation 2008:2::/64 0003000100d0f82233ac Ruijie(config-dhcp)# dns-server 2008:1::1 Ruijie(config-dhcp)# dns-server 2008:1::2 Ruijie(config-dhcp)# domain-name example.com Ruijie(config-dhcp)#exit Ruijie(config)# interface GigabitEthernet 0/1 Ruijie(config-if)# ipv6 dhcp server pool1
Verification	• Run the **show ipv6 dhcp pool** command to display the created configuration pool.
	Ruijie# show ipv6 dhcp pool DHCPv6 pool: pool1 Static bindings: Binding for client 0003000100d0f82233ac IA PD prefix: 2008:2::/64 preferred lifetime 3600, valid lifetime 3600 IANA address range: 2008:50::1/64 -> 2008:50::ffff:ffff:ffff:ffff/64 preferred lifetime 1000, valid lifetime 2000 DNS server: 2008:1::1 DNS server: 2008:1::2 Domain name: example.com

Common Errors

- The specified pool name is too long.
- The number of the configuration pools exceeds the system limit (256).
- The configuration is performed on other interfaces than the Switch Virtual Interface (SVI), routed port and L3 AP port.
- The number of interfaces configured with the DHCPv6 server service exceeds the system limit (256).
- The specified value of **valid lifetime** is smaller than that of **preferred lifetime**.

- An invalid IA_NA address is specified.
- The number of address ranges exceeds the system limit (20).
- When prefixes of statically bound addresses are configured, the specified DUIDs are too long.
- The number of prefixes of statically bound addresses exceeds the system limit (1024).
- When a local prefix pool is configured, the specified value of **valid lifetime** is smaller than that of **preferred lifetime**.
- The number of DNS servers exceeds the system limit (10).
- The number of domain names exceeds the system limit (10).
- The number of option52 addresses exceeds the system limit (10).

5.4.2 Configuring the DHCPv6 Relay

Configuration Effect

- A DHCPv6 relay agent can be configured for address allocation, prefix delegation and parameter allocation to enable communication between the DHCPv6 client and server on different links.

Notes

- A destination address must be specified. If the destination address is a multicast address (such as FF05::1:3), you also need to specify an egress interface.

Configuration Steps

↘ Configuring the DHCPv6 Relay Agent Function

- Mandatory.
- Unless otherwise specified, you should configure the DHCPv6 relay agent function on all devices that need to provide the DHCPv6 relay agent service.

Verification

- The DHCPv6 client and DHCPv6 server exchange messages through the relay agent.
- Check whether the interface is enabled with the DHCPv6 relay.
- Check whether the DHCPv6 relay agent can receive and send messages.

Related Commands

↘ Configuring the DHCPv6 Relay Agent Function

Command	**ipv6 dhcp relay destination** *ipv6-address* [*interface-type interface-number*]
Parameter Description	*ipv6-address*: Specifies the destination address of the relay agent. *interface-type*: Specifies the type of the destination interface (optional). *interface-number*: Specifies the destination interface number (optional).
Command	Interface configuration mode

Mode	
Usage Guide	All DHCPv6 packets from clients received by an interface enabled with the DHCPv6 relay function will be encapsulated and sent to a specified destination address (or multiple destination addresses) through a specified interface (optional).

Configuration Example

Configuring the DHCPv6 Relay

Configuration Steps	Specify an interface enabled with the relay service to forward received DHCPv6 client packets to a specified destination address through the specified interface (optional).
	`Ruijie#configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.` `Ruijie(config)#interface vlan 1` `Ruijie(config-if)#ipv6 dhcp relay destination 3001::2` `Ruijie(config-if)#ipv6 dhcp relay destination ff02::1:2 vlan 2`
Verification	Run the **show ipv6 dhcp relay destination all** command to display the configured destination addresses.
	`Interface:VLAN 1` `Destination address(es)  Output Interface` `3001::2` `ff02::1:2  VLAN 2`

Common Errors

- The configuration is performed on other interfaces than the Switch Virtual Interface (SVI), routed port and L3 AP port.

5.4.3 Configuring the DHCPv6 Client

Configuration Effect

- Enable a device to automatically request IPv6 addresses or related parameters from a server.

Notes

- The configuration must be performed on layer-3 interfaces.

Configuration Steps

Enabling the DHCPv6 Client and Requesting IANA Addresses

- Mandatory.

- Unless otherwise specified, you should enable the DHCPv6 client address request function on all devices that need to request addresses.

Enabling the DHCPv6 Client and Requesting Address Prefixes

- Mandatory.
- Unless otherwise specified, you should enable the DHCPv6 client prefix request function on all devices that need to request prefixes.

Enabling the Stateless Service of the DHCPv6 Client

- It is mandatory if the DHCPv6 client needs to obtain configuration parameters.

Verification

- Check whether the interface is enabled with the DHCPv6 client and check the addresses, prefixes and other configuration obtained on the interface.

Related Commands

Enabling the DHCPv6 Address Request Function

Command	**ipv6 dhcp client ia** [**rapid-commit**]
Parameter Description	**rapid-commit:** Permits the simplified message exchange process.
Command Mode	Interface configuration mode
Usage Guide	If the DHCPv6 client mode is not enabled, this command will enable the DHCPv6 client mode on the interface. After the **ipv6 dhcp client ia** command is configured, an IANA address request will be sent to the DHCPv6 server. The **rapid-commit** keyword permits the two-message exchange process between the client and server. If this keyword is configured, the Solicit message sent by the client contains the **rapid-commit** option.

Enabling the DHCPv6 Client Prefix Request

Command	**ipv6 dhcp client pd** *prefix-name* [**rapid-commit**]
Parameter Description	*prefix-name*: Indicates a IPv6 general prefix. **rapid-commit:** Permits the simplified message exchange process.
Command Mode	Interface configuration mode
Usage Guide	If the DHCPv6 client mode is not enabled, this command will enable the DHCPv6 client mode on the interface. After the **ipv6 dhcp client pd** command is configured, a prefix request will be sent to the DHCPv6 server. After receiving the prefix, the client will save the prefix in the IPv6 general prefix pool. Then, other commands and applications can use this prefix.

	The **rapid-commit** keyword permits the two-message exchange process between the client and server. If this keyword is configured, the Solicit message sent by the client contains the **rapid-commit** option.

Configuring Stateless Service

Command	**ipv6 nd other-config-flag**
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	Configure this command on a host that sends the RA message. Then, the host that receives the RA message obtains stateless configurations through the DHCPv6 client.

Configuration Example

Enabling the DHCPv6 Address Request Function

Configuration Steps	● Configure the DHCPv6 client address request function on an interface.
	`Ruijie(config)# interface GigabitEthernet 0/1` `Ruijie(config-if)# ipv6 dhcp client ia`
Verification	● Run the **show ipv6 dhcp interface** command to display whether the interface is enabled with the DHCPv6 client.
	`Ruijie#show ipv6 dhcp interface GigabitEthernet 0/1` `GigabitEthernet 0/1 is in client mode` `  Rapid-Commit: disable`

Enabling the DHCPv6 Client Prefix Request

Configuration Steps	● Configure the DHCPv6 client prefix request function on an interface.
	`Ruijie(config)# interface GigabitEthernet 0/1` `Ruijie(config-if)# ipv6 dhcp client pd pd_name`
Verification	● Run the **show ipv6 dhcp interface** command to display whether the interface is enabled with the DHCPv6 client.
	`Ruijie#show ipv6 dhcp interface GigabitEthernet 0/1` `GigabitEthernet 0/1 is in client mode` `  Rapid-Commit: disable`

Enabling the DHCPv6 Stateless Service

Configuration Steps	● Configure this command on an interface that sends the RA message.
	Ruijie# configure terminal Ruijie(config)# interface GigabitEthernet 0/1 Ruijie(config-if)# ipv6 nd other-config-flag
Verification	● Run the **show ipv6 dhcp interface** command to display whether an interface of the host obtains configuration parameters.
	Ruijie#show ipv6 dhcp interface GigabitEthernet 0/2 GigabitEthernet 0/2 is in client mode DNS server: 2001::1 Rapid-Commit: disable

Common Errors

- The DHCPv6 client address request is enabled on non-layer-3 interfaces.
- The DHCPv6 address request is enabled on interfaces enabled with the DHCPv6 relay or DHCPV6 server.
- The DHCPv6 client prefix request is enabled on non-layer-3 interfaces.
- The DHCPv6 prefix request is enabled on interfaces enabled with the DHCPv6 relay or DHCPV6 server.

5.5 Monitoring

Clearing

⚠ Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears DHCPv6 bindings.	**clear ipv6 dhcp binding** [*ipv6-address*]
Clears DHCPv6 server statistics.	**clear ipv6 dhcp server statistics**
Clears conflicted addresses on the DHCPv6 server.	**clear ipv6 dhcp conflict** { *ipv6-address* | * }
Clears the statistics on sent and received packets after the DHCPv6 relay is enabled on the current device.	**clear ipv6 dhcp relay statistics**
Restarts the DHCPv6 client.	**clear ipv6 dhcp client** *interface-type interface-number*

Displaying

Description	Command
Displays the DUID of a device.	**show ipv6 dhcp**
Displays address bindings on the DHCPv6 server.	**show ipv6 dhcp binding** [*ipv6-address*]
Displays DHCPv6 interface.	**show ipv6 dhcp interface** [*interface-name*]
Displays DHCPv6 pool.	**show ipv6 dhcp pool** [*poolname*]
Displays conflicted DHCPv6 addresses.	**show ipv6 dhcp conflict**
Displays the statistics on the DHCPv6 server.	**show ipv6 dhcp server statistics**
Displays the destination address of the DHCPv6 relay agent.	**show ipv6 dhcp relay destination** { **all** | *interface-type interface-number* }
Displays the statistics on sent and received packets after the DHCPv6 relay is enabled on a device.	**show ipv6 dhcp relay statistics**
Displays the local IPv6 prefix pool.	**show ipv6 local pool** [*poolname*]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs DHCPv6.	**debug ipv6 dhcp** [**detail**]

6 Configuring DNS

6.1 Overview

A Domain Name System (DNS) is a distributed database containing mappings between domain names and IP addresses on the Internet, which facilitate users to access the Internet without remembering IP strings that can be directly accessed by computers. The process of obtaining an IP address through the corresponding host name is called domain name resolution (or host name resolution).

Protocols and Standards

- RFC1034: DOMAIN NAMES - CONCEPTS AND FACILITIES
- RFC1035: DOMAIN NAMES - IMPLEMENTATION AND SPECIFICATION

6.2 Applications

Application	Description
Static Domain Name Resolution	Performs domain name resolution directly based on the mapping between a domain name and an IP address on a device.
Dynamic Domain Name Resolution	Obtains the IP address mapped to a domain name dynamically from a DNS server on the network.

6.2.1 Static Domain Name Resolution

Scenario

- Preset the mapping between a domain name and an IP address on a device.
- When you perform domain name operations (such as Ping and Telnet) through application programs, the system can resolve the IP address without being connected to a server on the network.

Deployment

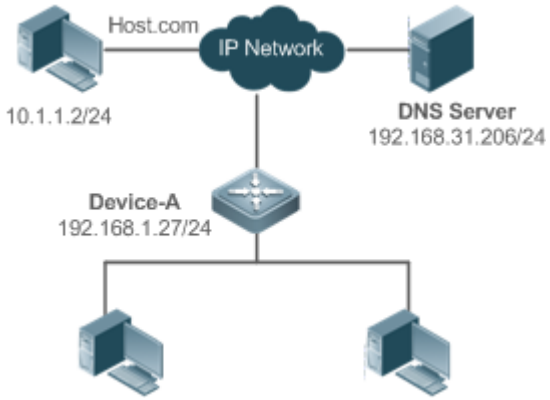
- Preset the mapping between a domain name and an IP address on a device.

6.2.2 Dynamic Domain Name Resolution

Scenario

- DNS Server is deployed on the network to provide the domain name service.
- Domain name "host.com" is deployed on the network.
- Device-A applies to DNS Server for domain name "host.com".

Figure 6-1 Dynamic Domain Name Resolution



Deployment

- Deploy DNS Server as the DNS server of Device-A.

6.3 Features

Basic Concepts

DNS

The DNS consists of a resolver and a DNS server. The DNS server stores the mappings between domain names and IP addresses of all hosts on the network, and implements mutual conversion between the domain names and IP addresses. Both the TCP and UDP port IDs of DNS are 53, and generally a UDP port is used.

Features

Feature	Description
Domain Name Resolution	IP addresses are obtained based on domain names from a DNS server or a local database.

6.3.1 Domain Name Resolution

Working Principle

Static Domain Name Resolution

Static domain name resolution means that a user presets the mapping between a domain name and an IP address on a device. When you perform domain name operations (such as Ping and Telnet) through application programs, the system can resolve the IP address without being connected to a server on the network.

Dynamic Domain Name Resolution

Dynamic domain name resolution means that when a user perform domain name operations through application programs, the DNS resolver of the system queries an external DNS server for the IP address mapped to the domain name.

The procedure of dynamic domain name resolution is as follows:

13. A user application program (such as Ping or Telnet) requests the IP address mapped to a domain name from the DNS resolver of the system.
14. The DNS resolver queries the dynamic cache at first. If the domain name on the dynamic cache does not expire, the DNS resolver returns the domain name to the application program.
15. If all domain names expire, the DNS resolver initiates a request for domain name-IP address conversion to the external DNS server.
16. After receiving a response from the DNS server, the DNS resolver caches and transfers the response to the application program.

Related Configuration

Enabling Domain Name Resolution

- By default, domain name resolution is enabled.
- Run the **ip domain-lookup** command to enable domain name resolution.

Configuring the IP Address Mapped to a Static Domain Name

- By default, no mapping between a domain name and an IP address is configured.
- Run the **ip host** command to specify the IPv4 address mapped to a domain name.
- Run the **ipv6 host** command to specify the IPv6 address mapped to a domain name.

Configuring a DNS Server

- By default, no DNS server is configured.
- Run the **ip name-server** command to configure a DNS server.

6.4 Configuration

Configuration	Description and Command	
Configuring Static Domain Name Resolution	⚠ Optional.	
	ip domain-lookup	Enables domain name resolution.
	ip host	Configures the IPv4 address mapped to a domain name.
	ipv6 host	Configures the IPv6 address mapped to a domain name.
Configuring Dynamic Domain Name Resolution	⚠ Optional.	
	ip domain-lookup	Enables domain name resolution.
	ip name-server	Configures a DNS server.

6.4.1 Configuring Static Domain Name Resolution

Configuration Effect

The system resolver resolves the IP address mapped to a domain name on a local device.

Configuration Steps

Enabling Domain Name Resolution

- The domain name resolution function is enabled by default.
- If this function is disabled, static domain name resolution does not take effect.

Configuring the IP Address Mapped to a Domain Name

- (Mandatory) Domain names to be used must be configured with mapped IP addresses.

Verification

- Run the **show run** command to check the configuration.
- Run the **show hosts** command to check the mapping between the domain name and the IP address.

Related Commands

Configuring the IPv4 Address Mapped to a Domain Name

Command	**ip host** *host-name ip-address*
Parameter Description	*host-name*: indicates a domain name. *ip-address*: indicates a mapped IPv4 address.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the IPv6 Address Mapped to a Domain Name

Command	**ipv6 host** *host-name ipv6-address*
Parameter Description	*host-name*: indicates a domain name. *ipv6-address*: indicates a mapped IPv6 address.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring Static Domain Name Resolution

Configuration Steps	● Set the IP address of static domain name www.test.com to 192.168.1.1 on a device. ● Set the IP address of static domain name www.testv6.com to 2001::1 on a device.

	Ruijie#configure terminal Ruijie(config)# ip host www.test.com 192.168.1.1 Ruijie(config)# ipv6 host www.testv6.com 2001::1 Ruijie(config)# exit
Verification	Run the **show hosts** command to check whether the static domain name entry is configured.
	Ruijie#show hosts Name servers are: Host type Address TTL(sec) www.test.com static 192.168.1.1 --- www.testv6.com static 2001::1 ---

6.4.2 Configuring Dynamic Domain Name Resolution

Configuration Effect

The system resolver resolves the IP address mapped to a domain name through a DNS server.

Configuration Steps

↘ Enabling Domain Name Resolution

- Domain name resolution is enabled by default.
- If this function is disabled, dynamic domain name resolution does not take effect.

↘ Configuring a DNS Server

- (Mandatory) To use dynamic domain name resolution, you must configure an external DNS server.

Verification

- Run the **show run** command to check the configuration.

Related Commands

↘ Configuring a DNS Server

Command	**ip name-server**{ *ip-address* | *ipv6-address* }
Parameter Description	*ip-address*: indicates the IPv4 address of the DNS server. *Ipv6-address*: indicates the IPv6 address of the DNS server.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring Dynamic Domain Name Resolution

Scenario **Figure 6-2**	
	Device resolves the domain name through the DNS server (192.168.10.1) on the network.
Configuration Steps	Set the IP address of the DNS server to 192.168.10.1 on the device.
	DEVICE#configure terminal DEVICE(config)# ip name-server 192.168.10.1 DEVICE(config)# exit
Verification	Run the **show hosts** command to check whether the DNS server is specified.
	Ruijie(config)#show hosts Name servers are: 192.168.10.1 static Host type Address TTL(sec)

6.5 Monitoring

Clearing

⚠ Running the **clear** command during device operation may cause data loss or even interrupt services.

Description	Command
Clears the dynamic host name cache table.	**clear host** [*host-name*]

Displaying

Description	Command
Displays DNS parameters.	**show hosts** [*host-name*]

Debugging

⚠ System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the DNS function.	**debug ip dns**

7 Configuring FTP Server

7.1 Overview

The File Transfer Protocol (FTP) server function enables a device to serve as an FTP server. In this way, a user can connect an FTP client to the FTP server and upload files to and download files from the FTP server through FTP.

A user can use the FTP server function to easily obtain files such as syslog files from a device and copy files to the file system of the device through FTP.

Protocols and Standards

- RFC959: FILE TRANSFER PROTOCOL (FTP)
- RFC3659: Extensions to FTP
- RFC2228: FTP Security Extensions
- RFC2428: FTP Extensions for IPv6 and NATs
- RFC1635: How to Use Anonymous FTP

7.2 Applications

Application	Description
Providing FTP Services in a LAN	Provides the uploading and downloading services for a user in a Local Area Network (LAN).

7.2.1 Providing FTP Services in a LAN

Scenario

Provide the uploading and downloading services for a user in a LAN.

As shown in Figure 7-1, enable the FTP server function only in a LAN.

- G and S are enabled with the FTP server function and layer-2 transparent transmission function respectively.
- A user initiates a request for FTP uploading and downloading services.

Figure 7-1

Remarks	G is an egress gateway device. S is an access device.

Deployment

- G is enabled with the FTP server function.
- As a layer-2 switch, S provides the function of layer-2 transparent transmission.

7.3 Features

Basic Concepts

FTP

FTP is a standard protocol defined by the IETF Network Working Group. It implements file transfer based on the Transmission Control Protocol (TCP). FTP enables a user to transfer files between two networked computers and is the most important approach to transferring files on the Internet. A user can obtain abundant Internet for free through anonymous FTP. In addition, FTP provides functions such as login, directory query, file operation, and other session control. Among the TCP/IP protocol family, FTP is an application-layer protocol and uses TCP ports 20 and 21 for transmission. Port 20 is used to transmit data and port 21 is used to transmit control messages. Basic operations of FTP are described in RFC959.

User Authorization

To connect an FTP client to an FTP server, you should have an account authorized by the FTP server. That is, a user can enjoy services provided by the FTP server after logging in to the FTP server with a user name and password. A maximum of 10 accounts can be configured, a maximum of 2 connections are allowed for each account, and a maximum of 10 connections are supported by the server.

FTP File Transmission Modes

FTP provides two file transmission modes:

- Text transmission mode (ASCII mode): It is used to transfer text files (such as .txt, .bat, and .cfg files). This mode is different from the binary mode in carriage return and line feed processing. In ASCII mode, carriage return and line feed are changed to local CRC characters, for example, \n in Unix, \r\n in Windows, and \r in Mac. Assume that a file being copied contains ASCII text. If a remote computer does not run Unix, FTP automatically converts the file format to suit the remote computer.
- Binary transmission mode: It is used to transfer program files (for example, .app, .bin and .btm files), including executable files, compressed files and image files without processing data. Therefore, Binary mode facilitates faster transfer of all files and more reliable transfer of ASCII files.

FTP Working Modes

FTP provides two working modes:

Figure 7-2

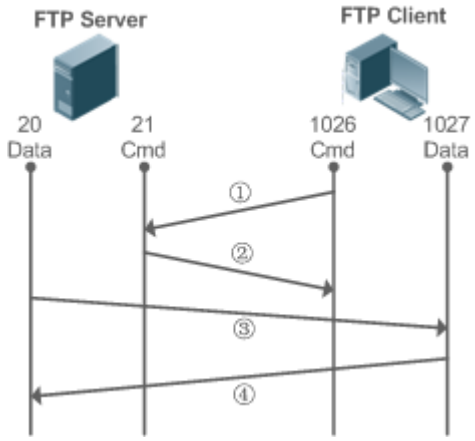


Figure 7-3

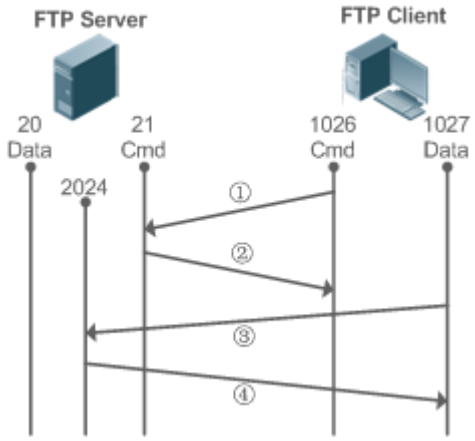


- Figure 7-2 shows the active (PORT) mode. The FTP client uses port 1026 to connect to the FTP server through port 21. The client sends commands through this channel. Before receiving data, the client sends the **PORT** command on this channel. The **PORT** command contains information on the channel port (1027) of the client for receiving data. The server uses port 20 to connect to the client through port 1027 for establishing a data channel to receive and transmit data. The FTP server must establish a new connection with the client for data transmission.
- Figure 7-3 shows the passive (PASV) mode. The process for establishing a control channel is similar to that in the PORT mode. However, after the connection is established, the client sends the **PASV** command rather than the **PORT** command. After receiving the **PASV** command, the FTP server enables a high-end port (2024) at random and notifies the client that data will be transmitted on this port. The client uses port 1027 to connect the FTP server through port 2024. Then, the client and server can transmit and receive data on this channel. In this case, the FTP server does not need to establish a new connection with the client.

Supported FTP Commands

After receiving an FTP connection request, the FTP server requires the client to provide the user name and password for authentication.

If the client passes the authentication, the FTP client commands can be executed for operations. The available FTP client commands are listed as follows:

ascii	delete	mdelete	mput	quit	send
bin	dir	mdir	nlist	recv	size
bye		mget		rename	system
cd	get	mkdir	passive		type
cdup		mls	put	rmdir	user
close	ls		pwd		

For usage of these FTP client commands, please refer to your FTP client software document. In addition, many FTP client tools (such as CuteFTP and FlashFXP) provide the graphic user interface. These tools facilitate operations by freeing users from configuring FTP commands.

Overview

Feature	Description
Enabling the FTP Server Function	Provides the functions of uploading, downloading, displaying, creating and deleting files for an FTP client.

7.3.1 Enabling the FTP Server Function

Working Principle

The basic working principle is described in the previous chapter. Ruijie devices provide FTP services after the user name, password, and top-level directory are configured.

Related Configuration

↘ Enabling the FTP Server Function Globally

The FTP server function is disabled by default.

Run the **ftp-server enable** command to enable the FTP server function.

You must enable the FTP server function globally before using it.

↘ Configuring a User Name, Password, and Top-Level Directory

There is no authorized user or top-level directory by default.

Run the **ftp-server username password** and **ftp-server topdir** commands to set an authorized user and top-level directory.

The three configurations above are mandatory; otherwise, the FTP server function cannot be enabled.

7.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions	(Mandatory) It is used to enable an FTP server.	
	ftp-server enable	Enables the FTP server function.
	ftp-server login timeout	Configures Login timeout for an FTP session.
	ftp-server login times	Configures the valid login count.
	ftp-server topdir	Configures the top-level directory of the FTP server.
	ftp-server username password	Configures a user name and password.
	Optional.	
	ftp-server timeout	Configures the idle timeout of an FTP session.

7.4.1 Configuring Basic Functions

Configuration Effect

- Create an FTP server to provide FTP services for an FTP client.

Notes

- The user name, password, and top-level directory need to be configured.
- To enable the server to close an abnormal session within a limited period, you need to configure the idle timeout of a session.

Configuration Steps

Enabling the FTP Server Function

- Mandatory.
- Unless otherwise noted, enable the FTP server function on every router.

Configuring a Top-Level Directory

- Mandatory.
- Unless otherwise noted, configure the top-level directory as the root directory on every router.

Configuring a User Name and Password for Login

- Mandatory.
- The lengths of the user name and password are restricted.

Configuring the Login Timeout for an FTP Session

- Optional.
- When the client is disconnected from the server due to an error or other abnormal causes, the FTP server may not know that the user is disconnected and continues to keep the connection. Consequently, the FTP connection is occupied for a long time and the server cannot respond to the login requests of other users. This configuration can ensure that other users can connect to the FTP server within a period of time upon an error.

Verification

Connect an FTP client to the FTP server.

- Check whether the client is connected.
- Check whether operations on the client are normal.

Related Commands

Enabling the FTP Server Function

Command	**ftp-server enable**
Parameter Description	**-**
Command Mode	Global configuration mode
Usage Guide	The client cannot access the FTP server unless the top-level directory, user name and password are configured. Therefore, it is recommended that you configure the top-level directory, user name and password for login by referring to the subsequent chapters before enabling the service for the first time.

Configuring the Valid Login Count

Command	**ftp-server login times***times*
Parameter Description	*times:* Indicates the valid login count, ranging from 1 to 10.
Command Mode	Global configuration mode
Usage Guide	The valid login count refers to the number of times you can perform account verification during an FTP session. The default value is 3, which means that your session will be terminated if you enter an incorrect user name or password for three times and other users can go online.

Configuring the Login Timeout for an FTP Session

Command	**ftp-server login timeout***timeout*

Parameter Description	*timeout*: Indicates the login timeout, ranging from 1 to 30 minutes.
Command Mode	Global configuration mode
Usage Guide	The login timeout refers to the maximum duration that the session lasts since being established. If you do not pass the password verification again during the login timeout, the session will be terminated to ensure that other users can log in.

Configuring the Top-Level Directory of the FTP Server

Command	**ftp-servertopdir***directory*
Parameter Description	*directory:* Indicates the user access path.
Command Mode	Global configuration mode
Usage Guide	If the top-level directory of the server is set to "/syslog", the FTP client can access only the files and directories in the "/syslog" directory on the device after login. Due to restriction on the top-level directory, the client cannot return to the upper directory of "/syslog".

Configuring a User Name and Password for Server Login

Command	**ftp-server username** *username* **password** [*type*] *password*
Parameter Description	*username*: Indicates a user name. *type*: 0 or 7. 0 indicates that the password is not encrypted (plaintext) and 7 indicates that the password is encrypted (cipher text). *password*: Indicates a password.
Command Mode	Global configuration mode
Usage Guide	The FTP server does not support anonymous login; therefore, a user name must be configured. A user name consists of up to 64 characters including letters, half-width digits and symbols without spaces. A password consists of only letters or digits. Spaces at the beginning and end of the password are ignored. Spaces inside the password are viewed as part of the password. A plaintext password consists of 1 to 25 characters. A cipher text password consists of 4 to 52 characters. User names and passwords must match. A maximum of 10 users can be configured. A username is exclusively associated with a password. Up to ten users can be configured.

Configuring the Idle Timeout for an FTP Session

Command	**ftp-Server timeout** *time*
Parameter Description	*time*: Indicates the idle timeout, ranging from 1 to 3,600 minutes.
Command	Global configuration mode

Mode	
Usage Guide	The idle timeout of a session refers to the duration from the end of an FTP operation to the start of the next FTP operation in an FTP session. After the server responds to an FTP client command operation (for example, after a file is completely transferred), the server starts to count the idle time again, and stops when the next FTP client command operation arrives. Therefore, the configuration of the idle timeout has no effect on some time-consuming file transfer operations.

Displaying Server Status

Command	**show ftp-server**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Run this command to display FTP server status.

Debugging

Command	**debug ftp-server pro/err**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Run this command to debug message/error events of the FTP server.

Configuration Example

Creating an FTP Server on an IPv4 Network

Scenario	● A TCP connection is established for transmission from a server to a client.
Configuration Steps	● Enable the FTP server function. ● Configure the top-level directory/syslog. ● Set the user name **user** and password to **password**. ● Set the session idle timeout to 5 minutes.
	`Ruijie(config)#ftp-server username user` `Ruijie(config)#ftp-server password password` `Ruijie(config)#ftp-server timeout 5` `Ruijie(config)#ftp-server topdir /` `Ruijie(config)#ftp-server enable`
Verification	● Run the **show ftp-server** command to check whether the configuration takes effect.
	`Ruijie#show ftp-server`

```
    ftp-server information
==================================
enable : Y
topdir : tmp:/
timeout: 10min
username:aaaa         password:(PLAINT)bbbb         connect num[2]
    [0]trans-type:BINARY (ctrl)server IP:192.168.21.100[21]
                               client IP:192.168.21.26[3927]
    [1]trans-type:ASCII (ctrl)server IP:192.168.21.100[21]
                               client IP:192.168.21.26[3929]
username:a1           password:(PLAINT)bbbb         connect num[0]
username:a2           password:(PLAINT)bbbb         connect num[0]
username:a3           password:(PLAINT)bbbb         connect num[0]
username:a4           password:(PLAINT)bbbb         connect num[0]
username:a5           password:(PLAINT)bbbb         connect num[0]
username:a6           password:(PLAINT)bbbb         connect num[0]
username:a7           password:(PLAINT)bbbb         connect num[0]
username:a8           password:(PLAINT)bbbb         connect num[0]
username:a9           password:(PLAINT)bbbb         connect num[0]
```

Common Errors

- No user name is configured.
- No password is configured.
- No top-level directory is configured.

7.5 Monitoring

Displaying

Description	Command
Displays the FTP server configuration.	show ftp-server

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the FTP server error events.	**debug ftp-server err**
Debugs the FTP server message events.	**debug ftp-server pro**

8 Configuring FTP Client

8.1 Overview

The File Transfer Protocol (FTP) is an application of TCP/IP. By establishing a connection-oriented and reliable TCP connection between the FTP client and server, a user can access a remote computer that runs the FTP server program.

An FTP client enables file transfer between a device and the FTP server over the FTP protocol. A user uses the client to send a command to the server. The server responds to the command and sends the execution result to the client. By means of command interaction, the user can view files in the server directory, copy files from a remote computer to a local computer, or transfer local files to a remote computer.

FTP is intended to facilitate sharing of program/data files and encourage remote operation (by using programs). Users do not need to be concerned with differences of different files systems on different hosts. Data is transmitted in an efficient and reliable manner. FTP enables remote file operation securely.

Ruijie FTP clients are different from standard FTP clients that run interactive commands. Instead, you enter the **copy** command in CLI to perform control-connection instructions such as **open**, **user**, and **pass**. After a control connection is established, the file transfer process starts, and then a data connection is established to upload or download files.

Old devices support TFTP. However, TFTP is used to transfer small files whereas FTP is used to transfer large files. Implementing FTP on a device enables the file transfer between the local device and other clients or servers.

Protocols and Standards

- RFC959: FILE TRANSFER PROTOCOL (FTP)

8.2 Applications

Application	Description
Uploading a Local File to a Remote Server	Local and remote files need to be shared, for example, uploading a local file to a remote server.
Downloading a File from a Remote Server to a Local Device	Local and remote files need to be shared, for example, downloading a file from a remote server to a local device.

8.2.1 Uploading a Local File to a Remote Server

Scenario

Local and remote files need to be shared, for example, uploading a local file to a remote server.

As shown in Figure 8-1, resources are shared only on the Intranet.

Figure 8-1

Deployment

- Implement only communication on the Intranet.
- Enable file uploading on the FTP client.
- Enable file uploading on the FTP server.

8.2.2 Downloading a File from a Remote Server to a Local Device

Scenario

Local and remote files need to be shared, for example, downloading a file from a remote server to a local device.

As shown in Figure 8-2, resources are shared only on the Intranet.

Figure 8-2

Deployment

- Implement only communication on the Intranet.
- Enable file downloading on the FTP client.
- Enable file downloading on the FTP server.

8.3 Features

Basic Concepts

Uploading FTP Files

Upload files from an FTP client to an FTP server.

Downloading FTP Files

Download files from an FTP server to an FTP client.

FTP Connection Mode

An FTP client and an FTP server can be connected in the active or passive mode.

FTP Transmission Mode

The transmission between an FTP client and an FTP server is available in two modes, namely, text (ASCII) and binary (Binary).

Specifying the Source Interface IP Address for FTP Transmission

An FTP client is configured with a source IP address for communication with an FTP server.

Overview

Feature	Description
Uploading FTP Files	Uploads files from an FTP client to an FTP server.
Downloading FTP Files	Downloads files from an FTP server to an FTP client.
FTP Connection Mode	Specifies the connection mode between an FTP client and an FTP server.
FTP Transmission Mode	Specifies the transmission mode between an FTP client and an FTP server.
Specifying the Source Interface IP Address for FTP Transmission	Configures a source IP address of an FTP client for communication with an FTP server.

8.3.1 Uploading FTP Files

FTP enables file uploading. Start the FTP client and FTP server simultaneously, and upload files from the FTP client to the FTP server.

8.3.2 Downloading FTP Files

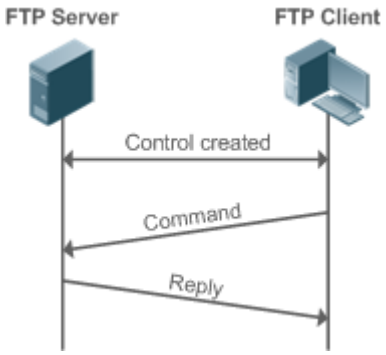
FTP enables file downloading. Start the FTP client and FTP server simultaneously, and download files from the FTP server to the FTP client.

8.3.3 FTP Connection Mode

FTP needs to use two TCP connections: one is a control link (command link) that is used to transfer commands between the FTP client and server; the other one is a data link that is used to upload or download data.

1. Control connection: Some simple sessions are enabled with the control connection only. A client sends a command to a server. After receiving the command, the server sends a response. The process is shown in Figure 8-3.

Figure 8-3 Control Connection



2. Control connection and data connection: When a client sends a command for uploading or downloading data, both the control connection and data connection need to be established.

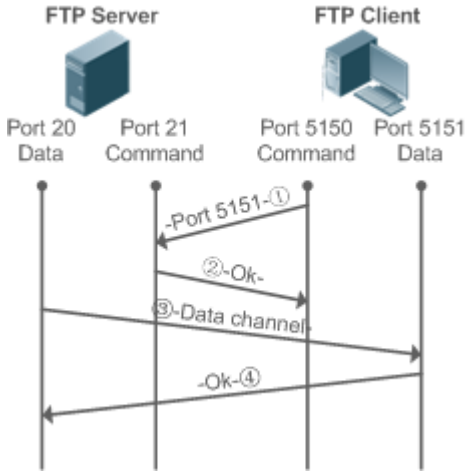
FTP supports two data connection modes: active (PORT) and passive (PASC). The two modes are different in establishing a data connection.

- Active mode

In this mode, an FTP server connects to an FTP client actively when a data connection is established. This mode comprises four steps:

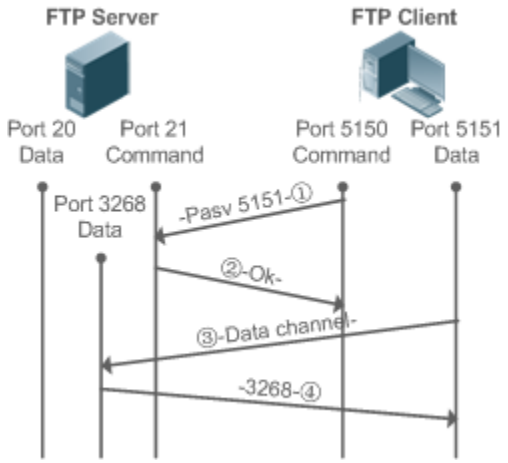
1. The client uses source port 5150 to communicate with the server through port 21 as shown in Figure 8-4 to send a connection request and tell the server that the port to be used is port 5151.
2. After receiving the request, the server sends a response OK(ACK). The client and server exchanges control signaling by console ports.
3. The server enables port 20 as the source port to send data to port 5151 of the client.
4. The client sends a response. Data transmission ends.

Figure 8-4 Active (PORT) Mode



- Passive mode

- Figure 8-5 Passive (PASV) Mode
  -



This mode is often set by the **passive** command. When a data connection is established, the FTP server is connected to the FPT client passively. This mode comprises four steps:

1. In the passive mode, the client initializes the control signaling connection. The client uses source port 5150 to connect to the server through port 21 as shown in Figure 8-5, and runs the **passive** command to request the server to enter the PASV mode.
2. The server agrees to enter the PASV mode, selects a port number greater than 1024 at random, and tells the port number to the client.
3. After receiving the message, the client uses port 5151 as shown in Figure 8-5 to communicate with the server through port 3268. Here, port 5151 is the source port and port 3268 is the destination port.
4. After receiving the message, the server sends data and responds an ACK(OK) response.

After the data connection is established, you can perform file uploading and downloading. Besides, you can perform some operations on the server file from the client.

The control connection for command and feedback transmission is always present whereas the data connection is established as required. Only an FTP client has the right to select and set the PASV or PORT mode. The FTP client sends a command to establish a data connection. Ruijie FTP clients use the PASV mode by default.

8.3.4 FTP Transmission Mode

FTP provides two transmission modes: text (ASCII) and binary (Binary). At present, Ruijie FTP clients support both the ASCII and Binary modes and use the BINARY mode by default.

- ASCII mode

The difference between the ASCII and Binary modes lies in carriage return and line feed processing. In ASCII mode, carriage return and line feed are changed to a local Carriage Return Character (CRC), for example, \n in Unix, \r\n in Windows, and \r in Mac.

- Binary mode

The Binary mode can be used to transfer executable files, compressed files and image files without processing data. For example, a text file needs to be transferred from Unix to Windows. When the Binary mode is used, the line breaks in Unix will not be converted from \r to \r\n; therefore in Windows, this file has no line feeds and displays many black squares. Therefore, Binary mode facilitates faster transfer of all files and more reliable transfer of ASCII files.

8.3.5 Specifying the Source Interface IP Address for FTP Transmission

An FTP client is configured with a source IP address for communication with an FTP server. In this way, the FTP client connects to the server and shares files with the server through the specified source IP address.

8.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions	(Mandatory) It is used to configure the functions of an FTP client.	
	copy flash	Uploads a file.
	copy ftp	Downloads a file.
Configuring Optional Functions	(Optional) It is used to configure the working mode of the FTP client.	
	ftp-client port	Sets the connection mode to active (port).
	ftp-client ascii	Sets the transmission mode to ASCII.
	ftp-client source-address	Configures the source IP address of the FTP client.
	default ftp-client	Restores the default settings, namely, connection mode set to passive (PASV), transmission mode to Binary and source IP address removed.

8.4.1 Configuring Basic Functions

Configuration Effect

- Implement file uploading and downloading.

Notes

- Pay attention to the command formats for uploading and downloading.

Configuration Steps

↘ Uploading a File

- This configuration is mandatory when a file needs to be uploaded.

- Configure the FTP URL as the destination address of **copy** in Privileged EXEC mode.

Downloading a File

- This configuration is mandatory when a file needs to be downloaded.
- Configure the FTP URL as the source address of **copy** in Privileged EXEC mode.

Verification

- Check whether the uploaded file exists on the FTP server.
- Check whether the downloaded file exists at the destination address.

Related Commands

Uploading a File

Command	**copy flash:**[*local-directory/*]*local-file* **ftp:** *//username:password@dest-address*[*/remote-directory*]*/remote-file*
Parameter Description	*local-directory:* Specifies a directory on the local device. If it is not specified, it indicates the current directory. *local-file:* Specifies a local file to be uploaded. *username*: Specifies a user name for accessing the FTP server, consisting of no more than 32 bytes and excluding delimiters such as /, :, @ and space. This parameter is mandatory. *password:* Specifies a password for accessing the FTP server, consisting of no more than 32 bytes and excluding delimiters such as /, :, @ and space. This parameter is mandatory. *dest-address:* Specifies an IP address for the FTP server. *remote-directory:* Specifies a directory on the server. *remote-file:* Renames the file on the server. ⚠ The directory specified by the *local-directory* field must have been created on the device. This command will not automatically create a directory.
Command Mode	Global configuration mode
Usage Guide	Run this command to upload a file from the flash of a local device to an FTP server.

Downloading an FTP File

Command	**copy ftp:***//username:password@dest-address*[*/remote-directory*]*/remote-file* **flash:**[*local-directory/*]*local-file*
Parameter Description	*username*: Specifies a user name for accessing the FTP server, consisting of no more than 32 bytes and excluding delimiters such as /, :, @ and space. This parameter is mandatory. *password:* Specifies a password for accessing the FTP server, consisting of no more than 32 bytes and excluding delimiters such as /, :, @ and space. This parameter is mandatory. *dest-address:* Specifies an IP address for the FTP server. *remote-directory:* Specifies a directory on the server.

	remote-file: Specifies a file to be downloaded. *local-directory:* Specifies a directory on the local device. If it is not specified, it indicates the current directory. *local-file:* Renames the file in the local flash. ⚠ The directory specified by the *local-directory* field must have been created on the device. This command will not automatically create a directory.
Command Mode	Global configuration mode
Usage Guide	Run this command to download a file from an FTP server to the flash of a local device.

Configuration Example

Uploading a File

Configuration Steps	Upload the **local-file** file in the **home** directory of a device to the **root** directory of an FTP server whose user name is **user**, password is **pass** and IP address is **192.168.23.69** and name the file as **remote-file**.
	`Ruijie# copy flash: home/local-file ftp://user:pass@192.168.23.69/root/remote-file`
Verification	Check whether the **remote-file** file exists on the FTP server.

Downloading a File

Configuration Steps	Download the **remote-file** file from the **root** directory of an FTP server whose user name is **user**, password is **pass** and IP address is **192.168.23.69** to the **home** directory of a device and save the file as **local-file**.
	`Ruijie# copy ftp://user:pass@192.168.23.69/root/remote-file flash: home/local-file`
Verification	Check whether the **remote-file** file exists in the **home** directory of the flash.

Common Errors

- The command formats for uploading and downloading are incorrect.
- The user name or password is incorrect.

8.4.2 Configuring Optional Functions

Configuration Effect

- Set the connection and transmission modes and configure a source IP address of the client for file uploading and download.

Notes

- N/A

Configuration Steps

Setting the Connection Mode to Active (Port)

- Optional.
- Configure the connection mode of FTP.

Setting the Transmission Mode to ASCII

- Optional.
- Configure the transmission mode of FTP.

Configuring the Source IP Address of the FTP Client

- Optional.
- Configure the source IP address of the FTP client.

Restoring the Default Settings

- Optional.
- Restore the default settings of the FTP client.

Verification

Run the **show run** command to check whether the configuration takes effect.

Related Commands

Setting the Connection Mode to Active (Port)

Command	**ftp-client port**
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to set the connection mode to active (port). The default connection mode is passive (PASV).

Configuring the Source IP Address of the FTP Client

Command	**ftp-client source-address** {*ip-address* | *ipv6-address* }
Parameter Description	*ip-address:* Specifies the IPv4 address of a local interface. *ipv6-address:* Specifies the IPv6 address of a local interface.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an interface IP address of the client for connection to the server. By default, the client is not configured with a local IP address. Instead, the route selects an IP address for the client.

Setting the Transmission Mode to ASCII

Command	ftp-client ascii
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to set the transmission mode to ASCII. The default transmission mode is Binary.

Restoring the Default Settings

Command	default ftp-client
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to restore the default settings, namely, connection mode set to passive (PASV), transmission mode to Binary and source IP address removed.

Configuration Example

Configuring Optional Functions

Configuration Steps	• Set the connection mode of FTP to port. • Set the transmission mode to ASCII. • Set the source IP address to 192.168.23.167.
	Ruijie# configure terminal Ruijie(config)# ftp-client ascii Ruijie(config)# ftp-client port Ruijie(config)# ftp-client source-address 192.168.23.167 Ruijie(config)# end
Verification	Run the **show run** command on the device to check whether the configuration takes effect. Ruijie# show run ! ftp-client ascii ftp-client port ftp-client vrf 123 port ftp-client vrf 123 ascii

	ftp-client source-address 192.168.23.167 !

Common Errors

- The source IP address is not a local IP address.

8.5 Monitoring

Displaying

Description	Command
Displays the FTP client configuration.	**show run**

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the FTP Client.	**debug ftp-client**

9 Configuring Tunnel Interfaces

9.1 Overview

Tunnel interfaces are virtual interfaces used to implement tunneling. A tunnel interface provides a standard transmission link and you do not need to specify a transport protocol or payload protocol. Each tunnel interface represents a transmission link.

Tunneling function includes the following parts:

- Payload protocol: Is used to encapsulate the data transmitted in tunnels. For example, the IPv4 and IPv6 protocols work as payload protocols. Generic routing encapsulation (GRE) tunnels can carry IPv4 or IPv6 data.
- Bearer protocol: Is used for secondary encapsulation and identification of the data to be transmitted. Among the tunnels described in this document, only the GRE tunnel uses a bearer protocol, that is, the GRE protocol. The other tunnels use the IPv4 and IPv6 protocols. Packets are encapsulated with outer IPv4 and IPv6 headers.
- Transport protocol: Is used to transmit the data encapsulated for the second time through a bearer protocol. Ruijie products use the widely applied IPv4 and IPv6 protocols as transport protocols.

The tunnel mode can be used to set up communication between two private networks running the same protocol through a heterogeneous public network.

Tunneling is applicable to the following scenarios:

- Because tunneling supports different payload protocols, it allows the communication between local networks running non-IP protocols through a single network (IP network). Because tunneling operates on routes running transport protocols (IP protocols), it allows wider application of the protocols with hop limit.
- Tunneling allows discrete subnets to be connected through a single network (IP network).
- Tunneling allows the virtual private network (VPN) feature to be enabled on wide area networks (WANs).

Encapsulated data is transmitted through tunnels, which is a complex process. In some cases, you need to pay attention to the following changes:

- Because a tunnel is a logical link, it appears to be a single hop in routing. However, actually its path cost may be more than one hop. When you use a tunnel for transmission, note that the route of the tunnel link is different from the actual route.
- When you configure a firewall or an access control list (ACL), take the tunnel configuration into consideration. The transmission bandwidth and maximum transmission unit (MTU) allowed by payload protocols are smaller than the theoretical values.

9.2 Applications

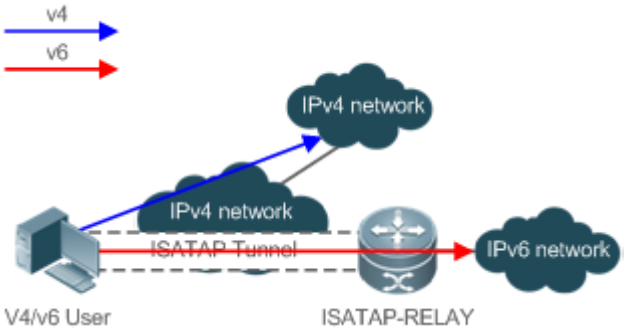
Application	Description
Accessing the IPv6 Sites on a Campus Network	Accesses the IPv6 sites on a campus network.

9.2.1 Accessing the IPv6 Sites on a Campus Network

Scenario

IPv6 servers are deployed on some campus networks, and PCs need to access the servers. The Intra-Site Automatic Tunnel Addressing Protocol (ISATAP) can be used to realize the access.

Figure 9-1



Remarks	ISATAP-RELAY supports tunneling. Users on the campus network can access IPv4 servers directly through the IPv4 network, but need to access IPv6 servers through the ISATAP tunnel.

Deployment

- IPv4 and IPv6 users access the IPv4 network by using IPv4 addresses.
- IPv4 and IPv6 users access the IPv6 network through the ISATAP tunnel.
- The ISATAP tunnel is established between PCs and the ISATAP-RELAY router.

9.3 Features

Basic Concepts

Tunnel MTU

- The MTU of a tunnel interface is smaller than that of a regular interface, such as a regular IPv4 over IPv4 tunnel. The maximum amount of data carried by a packet transmitted over the Ethernet is 1,460 bytes, not including the two IP headers. Therefore, the MTU of a tunnel interface is 1,480 bytes, not 1,500 bytes of a standard Ethernet interface.

Tunnel Path MTU

- A tunnel interface represents a virtual link. For an IPv4 over IPv4 tunnel, the MTU of the tunnel interface is the MTU of the tunnel link, that is, the MTU of the path between the local and peer ends of the tunnel When the routing path between the local and peer ends is changed, the MTU of the path may also be changed, which will affect the MTU of the tunnel interface.

Tunnel Encapsulation Limit

- Tunnel encapsulation is supported. For example, an IPv4 packet can be encapsulated with two or more IPv4 headers and then transmitted in an IPv4 over IPv4 tunnel. Tunnel encapsulation is intended for security protection and used sparingly. The amount of data to be transmitted is reduced after tunnel encapsulation. After routing through the forwarding information base (FIB), if the outbound interface is another tunnel interface, tunnel encapsulation occurs. If

the outbound interface is the local tunnel interface, infinite encapsulation occurs. (Ruijie products can detect this case and give prompts.)

Overview

Feature	Description
Tunnel Reachability Detection	Checks whether tunnel links are available.
Tunnel MTU Auto-Adjustment	Dynamically adjusts the MTU of a tunnel interface based on the changes of the path MTU of the tunnel link.
Tunnel Encapsulation Limit	Increases the maximum number of nested encapsulations of a packet based on actual requirements. (This feature is rarely used.)
Tunnel Data Validity Check	Adds checksum to the data transmitted in GRE tunnels to check whether an error occurs during transmission.

9.3.1 Tunnel Reachability Detection

Tunnel reachability detection is used to check whether the virtual link of a tunnel is available. Before this feature is enabled, a tunnel is considered as available if routing through the FIB based on the destination IP address is successful. After this feature is enabled, the criteria for determining tunnel availability are more accurate.

Working Principle

Each side of a tunnel periodically sends a keepalive packet to the other side. If one side does not receive a keepalive packet in the specified time, the tunnel is considered unavailable. Tunnel reachability detection is deployed only on one side of the tunnel.

Construction of a keepalive packet (Take IPv4 over IPv4 as an example): The packet is encapsulated with three IPv4 headers. The source address of the outer IPv4 header is the local address of the tunnel, and the destination address is the peer address. The local address and destination address of the middle IPv4 header are contrary to those of the outer and inner IPv4 headers.

One end of the tunnel encapsulates a keepalive packet with the preceding three IPv4 headers and sends it to the peer end. The peer end decapsulates the packet and returns the packet to the local end.

Upon receiving the packet, the local end of the tunnel which initially sends the packet continues to decapsulate the packet until only one IPv4 header remains. If the packet is a keepalive packet, the tunnel link is considered available.

Related Configuration

↘ Enabling Reachability Detection on Tunnel Interfaces

By default, reachability detection is disabled on tunnel interfaces.

To enable or disable reachability detection on tunnel interfaces, run the **keepalive** command.

For tunnel encapsulation, if the outermost tunnel is reachable, the other inner tunnels are also reachable.

9.3.2 Tunnel MTU Auto-Adjustment

The MTU of a tunnel interface is subject to the MTU of the tunnel link, that is, the path MTU. The MTU of the tunnel interface will be changed if a path is changed or the path MTU is changed. The tunnel MTU auto-adjustment feature is used to detect these changes and automatically adjust the MTU of the tunnel interface on the changes.

Working Principle

When a device receives an Internet Control Message Protocol (ICMP) error packet (PACKET TOO BIG), if the packet is encapsulated with a tunneled packet (an encapsulated IP packet), the faulty tunnel can be located based on the encapsulation information. The MTU of the tunnel interface will be changed based on the information in the "PACKET TOO BIG" packet.

Related Configuration

↘ Enabling Tunnel MTU Auto-Adjustment on Tunnel Interfaces

By default, tunnel MTU auto-adjustment is disabled on tunnel interfaces.

To enable or disable tunnel MTU auto-adjustment on tunnel interfaces, run the **tunnel path-mtu-discovery** command.

For tunnel encapsulation, tunnel MTU auto-adjustment needs to be enabled only for the outermost tunnel. The MTU of each inner tunnel is equal to the MTU of the outermost tunnel minus the length of the outer encapsulated header.

9.3.3 Tunnel Encapsulation Limit

In many cases, tunnel encapsulation is a deployment error and is actively deployed only in few cases. By default, Ruijie products allow four nested encapsulations of a packet at most. Administrators can use a command to change the limit.

Working Principle

If the peer end of tunnel interface A is a regular outbound interface, Ruijie products consider Tunnel Interface A as a regular tunnel interface.

If the peer end of tunnel interface A is another tunnel interface, Ruijie products consider Tunnel Interface A as a nested tunnel interface. If the outbound tunnel is a regular tunnel interface, Tunnel Interface A is called a single-nested tunnel. If the outbound tunnel is a single-nested tunnel, Tunnel Interface A is called a double-nested tunnel.

If the peer end of tunnel interface A is itself, infinite recursive encapsulation occurs. When Ruijie products detect infinite recursive encapsulation, they will output logs and disable Tunnel Interface A.

If the peer end of the tunnel is another tunnel interface, routing is performed based on the peer address of the tunnel interface. The actual outbound interface will be determined after multiple times of routing.

If the number of nested encapsulations on a tunnel interface exceeds the upper limit, Ruijie products will output logs and disable the tunnel interface.

Note that the tunnel encapsulation limit is a device-based feature and is different from the maximum number of encapsulated headers in a packet over a network.

Related Configuration

Configuring the Tunnel Encapsulation Limit on Tunnel Interfaces

By default, the maximum number of nested encapsulations of a packet on a tunnel interface is four. To change this limit, run the **tunnel nested-limit** command.

9.3.4 Tunnel Data Validity Check

In a GRE tunnel enabled with data validity check, the receiver checks the validity of the packets sent by the peer end to determine whether the packets are tampered or modified accidentally during transmission. In the case of long distance transmission, if the encapsulated data transmitted in GRE tunnels does not have similar validity check capabilities, you can enable tunnel data validity check.

Working Principle

A GRE tunnel calculates the checksum of the data to be encapsulated at the sender and encapsulates the checksum in the packet before sending the packet out.

Upon receiving the packet, the receiver recalculates the checksum and compares the calculated value to the checksum field in the packet. If the two do not match, the receiver considers that the packet has an error and discards it.

Related Configuration

Enabling Tunnel Data Validity Check on Tunnel Interfaces

By default, data validity check is disabled on tunnel interfaces.

To enable or disable data validity check on tunnel interfaces, run the **tunnel checksum** command.

Tunnel data validity check takes effect only when it is enabled on both ends of a GRE tunnel.

9.4 Configuration

Configuration	Description and Command	
Configuring Tunnel Interfaces	(Mandatory) It is used to create tunnels.	
	Interface tunnel	Creates a tunnel interface.
	tunnel source	Configures the local address of a tunnel.
Configuring a Tunnel Mode	(Optional) It is used to configure a tunnel mode.	
	tunnel mode	Configures a tunnel encapsulation mode.
Configuring a Peer Address	(Optional) It is used to configure the peer address of a tunnel.	
	tunnel destination	Configures the peer address of a tunnel.
Configuring the VPN of a VPN Tunnel	(Optional) It is used to configure the VPN tunnel.	
	tunnel vrf	Configures the VPN tunnel.

Configuration	Description and Command	
Configuring the TOS of a Tunnel	(Optional) It is used to configure the type of service (TOS) of a tunnel.	
	tunnel tos	Configures the TOS of a tunnel.
Configuring the TTL of a Tunnel	(Optional) It is used to configure the time to live (TTL) of a tunnel.	
	tunnel ttl	Configures the TTL of a tunnel.
Configuring the Tunnel Encapsulation Limit	(Optional) It is used to configure the maximum number of nested encapsulations of a packet.	
	tunnel nested-limit	Configures the maximum number of nested encapsulations of a packet.
Configuring Tunnel Data Validity Check	(Optional) It is used to enable data validity check for GRE tunnels.	
	tunnel checksum	Enables data validity check for GRE tunnels.
Configuring a Tunnel Key	(Optional) It is used to configure the check key of a tunnel.	
	tunnel key	Configures the check key of a GRE tunnel.

9.4.1 Configuring Tunnel Interfaces

Configuration Effect

- Create a tunnel interface.

Configuration Steps

Creating a Tunnel Interface

- Run the **interface tunnel** *number* command in global configuration mode to create a tunnel interface.
- The tunneling service is available only after a tunnel interface is created.

Verification

- Run the **show interfaces tunnel** *number* command to check whether the tunnel interface is created successfully.

Related Commands

Configuring a Tunnel Interface

Command	**interface tunnel** *number*
Parameter Description	*number*: Indicates the number of a tunnel interface.
Command Mode	Global configuration mode
Usage Guide	N/A

Checking the Tunnel Configuration

Command	**show interfaces tunnel** *number*
Parameter Description	*number*: Indicates the number of a tunnel interface.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Creating a Tunnel Interface

Configuration Steps	● Create a tunnel interface.
	Ruijie# configure terminal Ruijie(config)# interface tunnel 1 Ruijie(config-if-Tunnel 1)# end
Verification	● Check the configuration of the tunnel interface.
	Ruijie# show interfaces tunnel 1 ..... Tunnel attributes: ..... Tunnel protocol/transport is gre ip

Common Errors

- A tunnel interface cannot be created due to memory deficiency.
- A tunnel interface cannot be created due to insufficient hardware resource deficiency.

9.4.2 Configuring a Tunnel Mode

Configuration Effect

- Configure a tunnel encapsulation mode in tunnel interface configuration mode when you need to use a tunnel in non-default encapsulation mode.

Configuration Steps

Configuring a Tunnel Mode

- Optional.
- The default encapsulation mode for routers and gateway products is tunnel mode gre ip.

- To change the default encapsulation mode, run the **tunnel mode** command in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** *number* command to check whether the tunnel encapsulation mode is configured.

Related Commands

Configuring a Tunnel Mode

Command	**tunnel mode** { **gre ip | ipv6ip [6to4 | isatap]** }
Parameter Description	Each mode corresponds to different encapsulation format of the packets sent out by the tunnel interface. **gre ip** indicates that a packet is encapsulated with a GRE header and an IPv4 header in sequence and then is transmitted over a new IPv4 network. **ipv6ip** indicates that the tunnel interface carries only IPv6 packets and a packet sent out by the tunnel interface is encapsulated with an IPv4 header and then transmitted over a new IPv4 network. The preceding tunnels are manual tunnels, whereas IPv6IP 6RD, 6to4, and ISATAP are automatic tunnels. During packet encapsulation, the destination IPv4 address is mapped from the destination IPv6 address.
Command Mode	Interface configuration mode
Usage Guide	Both ends of a tunnel must be configured with the same encapsulation mode. Otherwise, the tunnel cannot work.

Configuration Example

Configuring the IPv4 over IPv4 Encapsulation Mode

Configuration Steps	● Configure the IPv4 over IPv4 encapsulation mode on a tunnel interface.
	`Ruijie# configure terminal` `Ruijie(config)# interface tunnel 1` `Ruijie(config-if-Tunnel 1)# tunnel mode ipip` `Ruijie(config)# end`
Verification	● Check the configuration of the tunnel interface.
	`Ruijie# show interfaces tunnel 1` `.....` `Tunnel attributes:` `.....` `  Tunnel protocol/transport is ipv6ip`

Common Errors

- A 6to4 tunnel or ISATAP tunnel is configured for a virtual routing and forwarding (VRF) instance that is already configured with a 6to4/ISATAP tunnel.

9.4.3 Configuring a Local Address

Configuration Effect

- Configure the local address of a tunnel.

Notes

- The local address of a tunnel must match the transport protocol used by the tunnel. Otherwise, the tunnel interface will not be up (be disabled).
- When the local address is specified indirectly by configuring another interface, the local address is the primary IPv4 address or the first global public IPv6 address of IPv6.

Configuration Steps

↘ Configuring a Local Address

- Mandatory.
- Run the **tunnel source** command in tunnel interface configuration mode to specify the local address of a tunnel.

Verification

- Run the **show interfaces tunnel** *number* command to display the local address of the tunnel.

Related Commands

↘ Configuring a Local Address

Command	**tunnel source** { *ip-address* | *interface-name interface-number* }
Parameter Description	**ip-address**: Indicates an IPv4 or IPv6 address. *Interface-name interface-number*: Indicates a Layer-3 interface.
Command Mode	Interface configuration mode
Usage Guide	If you specify an IPv4 or IPv6 address directly, you need to configure the address of the device.

Configuration Example

↘ Configuring a Local Address

Configuration Steps	• Configure the local address of a tunnel as 1.1.1.1.
	Ruijie# configure terminal Ruijie(config)# interface tunnel 1

	Ruijie(config-if-Tunnel 1)# tunnel mode ipv6ip Ruijie(config-if-Tunnel 1)# tunnel source 1.1.1.1
Verification	● Check the configuration of the tunnel interface.
	Ruijie# show interfaces tunnel 1 ..... Tunnel attributes: Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable Tunnel TOS/Traffic Class not set, Tunnel TTL 254 Tunnel config nested limit is 0, current nested number is 0 Tunnel protocol/transport ipv6ip Tunnel transport VPN is no set .....

9.4.4 Configuring a Peer Address

Configuration Effect

- A manual tunnel can be used (the tunnel interface is up) only after its peer address is configured.

Notes

- Peer addresses cannot be configured for automatic tunnels.

Configuration Steps

↘ Configuring a Peer Address

- The peer addresses must be configured for all tunnels except 6RD, 6to4, and ISATAP tunnels.
- Run the **tunnel destination** command in interface configuration mode to configure the peer address of a tunnel.

Verification

- Run the **show interfaces tunnel** command to check whether the destination address is configured.

Related Commands

↘ Configuring a Peer Address

Command	**tunnel destination** { *ip-address* }
Parameter Description	***ip-address***: Indicates an IPv4 or IPv6 address.
Command	Interface configuration mode

Mode	
Usage Guide	The peer address of a manual tunnel must be configured. The protocol suite type of the configured peer address must be consistent with the transport protocol used by the tunnel. If they are not consistent, the tunnel interface will be disabled (down).

Configuration Example

Configuring a Peer Address

Configuration Steps	● Configure the peer address of a tunnel as 2.2.2.2.
	Ruijie# configure terminal Ruijie(config)# interface tunnel 1 Ruijie(config-if-Tunnel 1)# tunnel mode ipv6ip Ruijie(config-if-Tunnel 1)# tunnel destination 2.2.2.2
Verification	● Check the configuration of the tunnel interface.
	Ruijie# show interfaces tunnel 1 ..... Tunnel attributes: Tunnel source: UNKNOWN, destination 2.2.2.2, unrouteable Tunnel TOS/Traffic Class not set, Tunnel TTL 254 Tunnel config nested limit is 0, current nested number is 0 Tunnel protocol/transport ipv6ip .....

Common Errors

- A peer address is configured for an automatic tunnel.
- The peer address configured for a tunnel is the same as that of another tunnel.

9.4.5 Configuring the VPN of a VPN Tunnel

Configuration Effect

- A device may have multiple network interfaces, which may belong to different VPNs. You can specify the VPN where a tunnel link will be created.

Notes

- If the specified VPN does not exist, the tunnel link can still be created, but the tunnel interface will be disabled (down).

Configuration Steps

Configuring the VPN of a VPN Tunnel

- Optional for all tunnels.
- By default, tunnels connected to other devices on the public network are created.
- To create tunnels connected to the devices on a VPN, run the **tunnel vrf** *vrf-name* command in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether the VPN is configured.

Related Commands

Configuring the VPN of a VPN Tunnel

Command	**tunnel vrf** *vrf-name*
Parameter Description	***vrf-name***: Indicates the VPN where the tunnel is located.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuring the VPN of a VPN Tunnel

Configuration Steps	● Configure VPN 1.
	Ruijie# configure terminal Ruijie(config)# interface tunnel 1 Ruijie(config-if-Tunnel 1)# tunnel mode ipv6ip Ruijie(config-if-Tunnel 1)# tunnel vrf VPN1
Verification	● Check the configuration of the tunnel interface.
	Ruijie# show interfaces tunnel 1 ..... Tunnel attributes: Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable Tunnel TOS/Traffic Class not set, Tunnel TTL 254

	Tunnel config nested limit is 0, current nested number is 0 Tunnel protocol/transport ipv6ip Tunnel transport VPN is VPN1 .....

Common Errors

- The transport layer protocol is IPv6, but the VPN uses the VRF of the IPv4 protocol suite.
- The VPN uses multi-protocol VRF, but the address family mapped to the tunneling protocol is not enabled.

9.4.6 Configuring the TOS of a Tunnel

Configuration Effect

- Specify the TOS or Traffic Class field in the transport protocol header.

Notes

- If the TOS or Traffic Class field in the transport protocol header is not specified, the TOS or Traffic Class field of the protocol is copied to the header.

Configuration Steps

↘ Configuring the TOS of a Tunnel

- Optional.
- To change the priority of tunnel data on a network, run the **tunnel tos** command in interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether the TOS is configured.

Related Commands

↘ Configuring the TOS of a Tunnel

Command	**tunnel tos** *number*
Parameter Description	***number***: Indicates the TOS of a tunnel.
Command Mode	Interface configuration mode
Usage Guide	By default, if the IPv4 protocol is used for the inner bearer and outer encapsulation in a tunnel, the TOS bytes in the inner IPv4 header are copied to the outer IPv4 header. If the IPv6 protocol is used for the inner bearer and outer encapsulation in a tunnel, the Traffic Class 8 bit in the inner IPv6 header is copied to the outer IPv6 header. In other cases, the TOS field in the outer IPv4 header and the Traffic Class field in the IPv6 header are 0.

Configuration Example

Configuring the TOS of a Tunnel

Configuration Steps	● Configure the TOS of a tunnel.
	Ruijie# configure terminal Ruijie(config)# interface tunnel 1 Ruijie(config-if-Tunnel 1)# tunnel mode ipv6ip Ruijie(config-if-Tunnel 1)# tunnel tos 2
Verification	● Check the configuration of the tunnel interface.
	Ruijie# show interfaces tunnel 1 ..... Tunnel attributes: Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable Tunnel TOS/Traffic Class 0x2, Tunnel TTL 254 Tunnel config nested limit is 0, current nested number is 0 Tunnel protocol/transport ipv6ip Tunnel transport VPN is VPN1 .....

9.4.7 Configuring the TTL of a Tunnel

Configuration Effect

- Specify the TTL or hop limit of tunnel encapsulation protocol headers.

Configuration Steps

Configuring the TTL of a Tunnel

- Optional.
- By default, the TTL is 254, which is the maximum value.
- To change the tunnel link length limit, run the **tunnel ttl** command.

Verification

- Run the **show interfaces tunnel** command to check whether the TTL is configured.

Related Commands

Configuring the TTL of a Tunnel

Command	**tunnel ttl** *hop-limit*
Parameter Description	*hop-limit*: Indicates the hop limit of a tunnel.
Command Mode	Global configuration mode
Usage Guide	The hop limit specifies the maximum number of routers that a packet can pass through. The default value is 254. This command is used to change the hop quantity limit.

Configuration Example

Configuring the TTL of a Tunnel

Configuration Steps	● Configure the TTL of a tunnel.
	Ruijie# configure terminal Ruijie(config)# interface tunnel 1 Ruijie(config-if-Tunnel 1)# tunnel mode ipv6ip Ruijie(config-if-Tunnel 1)# tunnel ttl 3
Verification	● Check the configuration of the tunnel interface.
	Ruijie# show interfaces tunnel 1 ..... Tunnel attributes: Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable Tunnel TOS/Traffic Class 0x2, Tunnel TTL 3 Tunnel config nested limit is 0, current nested number is 0 Tunnel protocol/transport ipv6ip Tunnel transport VPN is VPN1

9.4.8 Configuring Tunnel Reachability Detection

Configuration Effect

- Determine the availability of tunnels more accurately through tunnel reachability detection.

Configuration Steps

Configuring Tunnel Reachability Detection

- Optional for manual tunnels. Automatic tunnels do not support reachability detection.
- To dynamically monitor the availability of tunnel links, configure tunnel reachability detection in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether tunnel reachability detection is configured.

Related Commands

↘ Configuring Tunnel Reachability Detection

Command	**keepalive** [*seconds* [*retries*]]
Parameter Description	***seconds***: Indicates the interval at which keepalive packets are retransmitted, in the unit of seconds. *retries*: Indicates the number of times keepalive packets are retransmitted.
Command Mode	Interface configuration mode
Usage Guide	Manual tunnels support reachability detection, whereas automatic tunnels do not support it. By default, tunnel reachability detection is disabled. A tunnel interface is up if the route to the destination IP address can be found in the routing table of the device. After tunnel reachability detection is enabled, the tunnel interface is up if keepalive packets are sent and received correctly.

Configuration Example

↘ Configuring Tunnel Reachability Detection

Configuration Steps	● Configure tunnel reachability detection.
	`Ruijie# configure terminal` `Ruijie(config)# interface tunnel 1` `Ruijie(config)# tunnel mode ipv6ipRuijie(config)# keepalive 3 5`
Verification	● Check the configuration of the tunnel interface.
	`Ruijie# show interfaces tunnel 1` `Index(dec):11 (hex):b` `...` `Keepalive interval is 3 sec ,retries 5.`

9.4.9 Configuring Tunnel Path MTU Discovery

Configuration Effect

- Configure tunnel path MTU discovery to allow the MTU of a tunnel interface to be adjusted automatically based on the changes of the route MTU. Before this feature is configured, the MTU of the tunnel interface is equal to the MTU of the transport protocol minus the length of the header encapsulated through a transport protocol.

Configuration Steps

↘ Configuring Tunnel Path MTU Discovery

- Optional for manual tunnels. Automatic tunnels do not support tunnel path MTU discovery.
- To dynamically monitor and adjust the MTUs of tunnel links, configure tunnel path MTU discovery in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether tunnel path MTU discovery is configured.

Related Commands

↘ Configuring Tunnel Path MTU Discovery

Command	**tunnel path-mtu-discovery** [**age-timer** {*aging-mins* | **infinite**} | **min-mtu** *mtu-bytes*]
Parameter Description	*aging-mins*: Indicates the interval at which the MTU of a tunnel interface ages, in the unit of minutes. **infinite** indicates that the MTU never ages. *mtu-bytes*: Indicates the minimum value of the MTU.
Command Mode	Global configuration mode
Usage Guide	Use this command to realize dynamic monitoring and automatic change of the MTUs of tunnel links. You can configure the monitoring frequency and the lower limit of MTU change. Tunnel path MTU discovery has three states: init, learning, and keep. ● init indicates that detection is not initiated. ● learning indicates that dynamic learning is in progress. ● keep indicates that dynamic MTU adjustment is completed and the next round of adjustment is ready. Tunnel path MTU discovery depends on the "ICMP Packet Too Big" error packet returned by a device. If the packet is filtered by an in-between device, the discovery results will be inaccurate.

Configuration Example

↘ Configuring Tunnel Path MTU Discovery

Configuration Steps	● Configure tunnel path MTU discovery.

	Ruijie# configure terminal Ruijie(config)# interface tunnel 1 Ruijie(config)# tunnel mode ipv6ip Ruijie(config)# tunnel path-mtu-discovery
Verification	● Check the configuration of the tunnel interface.
	Ruijie# show interfaces tunnel 1 ... Tunnel transport VPN is no set Path MTU Discovery state:init, ager 10 mins, min MTU 92

Common Errors

- Tunnel path MTU discovery is enabled for automatic tunnels.

9.4.10 Configuring the Tunnel Encapsulation Limit

Configuration Effect

- Change the maximum number of nested encapsulations allowed by the outer protocol of a tunnel.

Notes

- In many cases, the tunnel encapsulation limit does not need to be changed.

Configuration Steps

↘ Configuring the Tunnel Encapsulation Limit

- By default, Ruijie products allow a maximum of four nested encapsulations of a packet. This limit can meet requirements in many scenarios.
- To change the limit, run the **tunnel nested-limit** *number* command in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether the tunnel encapsulation limit is configured.

Related Commands

↘ Configuring the Tunnel Encapsulation Limit

Command	**tunnel nested-limit** *number*
Parameter Description	*number*: Indicates the maximum number of nested encapsulations of a packet.

Command Mode	Interface configuration mode
Usage Guide	Ruijie products automatically discover tunnel multi-encapsulation and prevent excessive nested encapsulations. Only manual tunnels support the tunnel encapsulation limit, whereas automatic tunnels do not support it. The tunnel encapsulation limit is a device-based feature and indicates the maximum number of times a packet is encapsulated from its entrance to the device to exit.

Configuration Example

Configuring the Tunnel Encapsulation Limit

Configuration Steps	● Configure the tunnel encapsulation limit.
	Ruijie# configure terminal Ruijie(config)# interface tunnel 1 Ruijie(config-if-Tunnel 1)# tunnel mode ipv6ip Ruijie(config-if-Tunnel 1)# tunnel nested-limit 8
Verification	● Check the configuration of the tunnel interface.
	Ruijie# show interfaces tunnel 1 ..... Tunnel attributes: Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable Tunnel TOS/Traffic Class 0x2, Tunnel TTL 3 Tunnel config nested limit is 8, current nested number is 0 Tunnel protocol/transport ipv6ip Tunnel transport VPN is VPN1 .....

Common Errors

- The tunnel encapsulation limit is configured for automatic tunnels.

9.4.11 Configuring Tunnel Data Validity Check

Configuration Effect

- Configure tunnel data validity check to determine whether the data carried by tunnels is changed during transmission. If the data is changed, it is considered as corrupted and will be discarded. If the data carried by a tunnel does not have the validity check feature, you can enable the data validity check feature of the tunnel.

Notes

- Only GRE tunnels support data validity check.

Configuration Steps

Configuring Tunnel Data Validity Check

- Optional.
- If application protocols do not support data validity check, you can enable the data validity check feature of GRE tunnels.
- To enable tunnel data validity check, run the **tunnel checksum** command in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether tunnel data validity check is enabled.

Related Commands

Configuring Tunnel Data Validity Check

Command	**tunnel checksum**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Use this command to enable the data validity check feature of a GRE tunnel if the service data carried in the GRE tunnel does not support validity check. Data validity check must be configured on both ends of a tunnel. The sender adds the checksum to an encapsulated packet. The receiver calculates the checksum of the packet and compares it to the checksum provided by the sender. If they are consistent, the packet is valid. Otherwise, the packet is invalid.

Configuration Example

Configuring Tunnel Data Validity Check

Configuration Steps	• Configure data validity check in a tunnel.
	`Ruijie# configure terminal` `Ruijie(config)# interface tunnel 1` `Ruijie(config-if-Tunnel 1)# tunnel mode gre ip`

	Ruijie(config-if-Tunnel 1)# tunnel checksum
Verification	● Check the configuration of the tunnel interface.
	Ruijie# show interfaces tunnel 1 ..... Tunnel attributes: Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable Tunnel TOS/Traffic Class 0x2, Tunnel TTL 3 Tunnel config nested limit is 8, current nested number is 0 Tunnel protocol/transport gre ip Key disabled, Sequencing disabled Checksumming of packets enabled Tunnel transport VPN is VPN1 .....

Common Errors

- Data validity check is configured for regular tunnels (non-GRE tunnels).

9.4.12 Configuring a Tunnel Key

Configuration Effect

- By configuring the key of a tunnel interface, you can ensure the security of both ends of the tunnel to some extent, and also prevent malicious probe and attacks.

Notes

- Each packet encapsulated in the GRE format contains the configured key, but the attempt to ensure security through the key is inconsiderate.
- Both ends of a tunnel must use the same key settings.

Configuration Steps

↘ Configuring a Tunnel Key

- Optional.
- You can configure different keys to segregate the data carried in a GRE tunnel.
- To configure a tunnel key, run the **tunnel key** *key-value* command in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether the tunnel key is configured.

Related Commands

Configuring a Tunnel Key

Command	**tunnel key** *key-value*
Parameter Description	*key-value*: Indicates the value of a tunnel key.
Command Mode	Interface configuration mode
Usage Guide	The sender encapsulates the key in a packet. The receiver compares the local key to the key in the packet. If they are inconsistent, the packet is discarded.

Configuration Example

Configuring a Tunnel Key

Configuration Steps	● Configure a tunnel key.
	Ruijie# configure terminal Ruijie(config)# interface tunnel 1 Ruijie(config-if-Tunnel 1)# tunnel mode gre ip Ruijie(config-if-Tunnel 1)# tunnel key 10
Verification	● Check the configuration of the tunnel interface.
	Ruijie# show interfaces tunnel 1 …… Tunnel attributes: Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable Tunnel TOS/Traffic Class 0x2, Tunnel TTL 3 Tunnel config nested limit is 8, current nested number is 0 Tunnel protocol/transport gre ip Key 0xa, Sequencing disabled Checksumming of packets enabled Tunnel transport VPN is VPN1 ……

Common Errors

- Tunnel keys are configured for regular tunnels (non-GRE tunnels).

9.5 Monitoring

Displaying

Description	Command
Displays the information about a tunnel interface.	**show interfaces tunnel** *number*

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables tunnel interface debugging.	**debug tunnel**

10 Configuring Network Communication Test Tools

10.1 Overview

Network communication test tools can be used to check the connectivity of a network and helps you analyze and locate network faults. Network communication test tools include Packet Internet Groper (PING) and Traceroute. Ping is used to check the connectivity and delay of a network. A greater delay indicates a slower network speed. Traceroute helps you learn about the topology of physical and logical links and transmission rate. On a network device, you can run the **ping** and **traceroute** commands to use the two tools respectively.

Protocols and Standards

- RFC792: Internet Control Message Protocol
- RFC4443: Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification

10.2 Applications

Application	Description
End-to-End Connectivity Test	Both the network device and the destination host are connected to the IP network and configured with IP addresses.
Host Route Test	Both the network device and the destination host are connected to the IP network and configured with IP addresses.

10.2.1 End-to-End Connectivity Test

Scenario

As shown in Figure 10-1, Network Device A and Target Host B are connected to the IP network.

If both the network device and the target host are connected to the IP network, the end-to-end connectivity test aims to check whether IP packets can be transmitted between the two ends. The target host can be the network device itself. In this case, the connectivity test aims to check the network interface and TCP/IP configurations on the device.

Figure 10-1

Deployment

Execute the ping function on the network device.

10.2.2 Host Route Test

Scenario

As shown in Figure 10-2, Network Device A and Target Host B are connected to the IP network.

If both the network device and the target host are connected to the IP network, the host route test aims to check gateways (or routers) that IP packets pass through between the two ends. Generally, the target host is not within the same IP network segment as the network device.

Figure 10-2

Deployment

Execute the traceroute function on the network device.

10.3 Features

Overview

Feature	Description
Ping Test	Test whether the specified IPv4 or IPv6 address is reachable and display the related information.
Traceroute Test	Display the gateways that IPv4 or IPv6 packets pass through when transmitted from the source to the destination.

10.3.1 Ping Test

Working Principle

The ping tool sends an Internet Control Message Protocol (ICMP) Request message to the destination host to request the for an ICMP Echo Reply message. In this way, the ping tool determines the delay and the connectivity between the two network devices.

Related Configuration

- Run the **ping** command.

10.3.2 Traceroute Test

Working Principle

The traceroute tool uses the Time To Live (TTL) field in the headers of the ICMP and IP messages for the test First, the traceroute tool on the network device sends an ICMP Request message with TTL 1 to the destination host. After receiving

the message, the first router on the path decreases the TTL by 1. As the TTL becomes 0, the router drops the packets and returns an ICMP time exceeded message to the network device. After receiving this message, the traceroute tool learns that this router exists on this path, and then sends an ICMP Request packet with TTL 2 to the destination host to discover the second router. Each time the traceroute tool increases the TTL in the ICMP Request message by 1 to discover one more router. This process is repeated until a data packet reaches the destination host. After the packet reaches the destination host, the host returns an ICMP Echo message instead of an ICMP time exceeded message to the network device. Then, the traceroute tool finishes the test and displays the path from the network device to the destination host.

Related Configuration

- Run the **traceroute** command.

10.4 Configuration

Configuration	Description and Command	
Ping Test	(Optional) It is used to check whether an IPv4 or IPv6 address is reachable.	
	ping	Executes the Ping function.
Traceroute Test	(Optional) It is used to display the gateways that IPv4 or IPv6 packets pass through when transmitted from the source to the destination.	
	traceroute	Executes the traceroute function.

10.4.1 Ping Test

Configuration Effect

After conducting a ping test on a network device, you can learn whether the network device is connected to the destination host and whether packets can be transmitted between the network device and the destination host.

Notes

The network device must be configured with an IP address.

Configuration Steps

- To check whether an IPv4 address is reachable, use the **ping IPv4** command.
- To check whether an IPv6 address is reachable, use the **ping IPv6** command.

Verification

Run the **ping** command to display related information on the command line interface (CLI) window.

Related Commands

↘ **Ping IPv4**

Command	**ping** [**oob** | **ip**] [*address* [**via** *mgmt-name*] [**length** *length*] [**ntimes** *times*] [**timeout** *seconds*] [**data** *data*] [**source** *source*] [**df-bit**] [**validate**] [**detail**] [**interval** millisecond] [**out-interface** interface]
Parameter Description	*oob:* Indicates out-of-band management. This parameter must be configured if the MGMT port is specified as the source port. *address*: Specifies the destination IPv4 address or domain name. **via**: If a device supports multiple MGMT ports, that is, multiple MGMT ports are displayed in the **show interface brief** command output, you are advised to add **via mgmt xxx** to the ping command. *mgmt-name:* Specifies the MGMT port in OOB mode. *length*: Specifies the length of the data packet. The value ranges from 36 to 18, 024. The default length is 100. *times*: Specifies the number of probes. The value ranges from 1 to 4, 294, 967, 295 *seconds*: Specifies the timeout. The value ranges from 1s to 10s. *data*: Specifies the data in the packet. The data is a string of 1 to 255 bytes. By default, the string is "abcd". *source*: Specifies the source IPv4 address or source port of the packet. The loopback interface address, for example, 127.0.0.1, cannot be used as the source address. **df-bit**: Configures the DF bit of the IP address. When the DF bit is set to 1, the packet is not fragmented. By default, the DF bit is 0. **validate**: Configures whether to verify the response packet. **detail**: Configures whether to display the Echo Reply message in detail. By default, only the exclamation mark (!) and dot (.) are displayed. interface: Specifies the interface for sending the data packets. millisecond: Specifies the interval at which the ping packet is sent. The value ranges from 50 ms to 300,000 ms. The default interval is 100 ms.
Command Mode	In User EXEC mode, you can execute only the basic ping function. In Privileged EXEC mode, you can execute the extended ping function. In other configuration modes, you can run the **do** command to execute the extended ping function. For details about the configuration, see the description about the **do** command.
Configuration Usage	When the ping function is executed, information about the response (if any) will be displayed, and then related statistics will be output. Using the extended ping function, you can specify the number, length and timeout of packets to be sent. Like the basic ping function, related statistics will be output. To use the domain name, you must first configure the domain name server (DNS). For details about the configuration, see *Configuring DNS*.

Ping IPv6

Command	**ping** [**oob** | **ipv6**] [*ip-address* [**via** *mgmt-name*] [**length** *length*] [**ntimes** *times*] [**timeout** *seconds*] [**data** *data*] [**source** *source*] [**detail**] [**interval** *millisecond*] [**out-interface** *interface*]
